

FIELD-MARSHAL LORD GRENFELL, G.C.B., G.C.M.G., LL.D.

AN
ILLUSTRATED WEEKLY JOURNAL
OF
Horticulture in all its Branches.

Founded by W. Robinson in 1871.

EDITED BY HERBERT COWLEY.

VOL. LXXIX. CHRISTMAS, 1915.

LONDON.

Office: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.

Published by "COUNTRY LIFE," Ltd., 20, Tavistock Street, Covent Garden, W.C., and by
GEORGE NEWNES, Ltd., 8-11, Southampton Street, Strand.

THIS VOLUME OF "THE GARDEN"

is dedicated by permission to

FIELD-MARSHAL LORD GRENFELL,

G.C.B., G.C.M.G., LL.D.

(President of the Royal Horticultural Society.)

WHEN Field-Marshal Lord Grenfell accepted the Presidency of the Royal Horticultural Society in the spring of 1913, the cloud of the great European war was not apparent. It therefore appears the more fortunate that he should have consented to preside over this great National Society at a time when his knowledge, experience and connections are invaluable to the Society over which he exercises a wise and guiding hand. Ever since the revival of the Society in the eighties, there almost seems to have been some higher care watching over it. When difficulties have threatened, they have been removed in remarkable ways, leaving the Society stronger than ever and in a better position to pursue the good work it is doing in increasing beauty, happiness and health throughout this fair land.

Lord Grenfell has been devoted to the art of gardening for the greater portion of his life. In the many parts of the globe where he has been stationed, he has succeeded in creating a garden for himself. He was probably the first to grow English Roses in Malta. He imported a large number there and grew them successfully. When in Egypt he founded a horticultural society, which became influential in improving the cultivation of flowers, despite the difficulties involved by the annual rise of the Nile. In late years Lord Grenfell has taken the keenest interest in his beautiful garden at Overstone, near Northampton.

Lord Grenfell entered the Army in 1859 and served in the Kaffir and Zulu Wars of 1878-79. He was Quartermaster-General in the Transvaal in 1881-82. Between 1882 and 1892 he was occupied in the Egyptian and Nile Expeditions, and was Sirdar of the Egyptian Army from 1885 to 1892. Subsequently, Lord Grenfell was Inspector-General of the Auxiliary Forces, Governor and Commander-in-Chief of Malta, for some time Commander of the 4th Army Corps and for five years Commander-in-Chief in Ireland. In recognition of his great services, Lord Grenfell was raised to the peerage in 1902.

It falls to the lot of very few men to gain such distinguished honours, but one tribute very dear to him is that of his late and gallant nephew, Captain Francis O. Grenfell, who was the first officer to win the Victoria Cross in the present war. Referring to his uncle, Captain Francis Grenfell in his will, which has been recently proved, says: "I should like to express my deep gratitude for his kindness to me during my lifetime, ever since the day when he decided I should go into the Army at his expense. I have endeavoured to base my career on his example." He has, since the death of my father, done everything that a father could do for me."

INDEX.

- Abutilon Triumph, 496
 Acacia, False, as a hedge plant, 133; platyptera, 25, 551
 Achillea Ostrifolia, 315
 Aconites, Winter, and Snowdrops, 97
 Actinidia chinensis, 589, 610
 Actinidias, two climbing, 565
 Æsculus parviflora, 436; plantiærensis, 311
 Agave americana, 554
 Agrostis nebulosa, 95
 Ailantus glandulosa, a noble group of, 242
 Akebia quinata, 529
 Allium kansuense, 543
 Alpines as border plants in Scotland, 337; increasing, 340; in Yunnan, Mr. George Forrest on, 347; late-flowering, 506, 541, 573; under glass, 121
 Alyssum spinosum, 302
 Amaryllis, the, after flowering, 263
 Anemone blanda, 217; fulgens, how to grow, 207; japonica Kentish White, 431; nemorosa bosniaca, 211; Pulsatilla, 181; rupicola, 273; sylvestris, 277
 Annual, a good hardy, for edgings, 140; flowers suitable for cutting, 103
 Annuals at Reading and Slough, 131; between shrubs, 372; for beds, 23; hardy, among shrubs, 127; in border, 179; sowing late, 265; the best climbing, 201

 Spinach, a hint on cooking, 122; New Zealand, 181, 265, 278
Spiraea Aitchisonii, 433
 Spray nozzles, trial of, at Wisley, 121
 Spring effect, a charming, 205; the fragrance of, 296
 Spruce, the Norway, as a hedge plant, 384
 Squill, the Spanish, 265
Stachys corsica and *Asperula suberosa*, 467
Stachyurus chinensis, 182
 Starworts, the Italian, 558
Statice latifolia, propagating, by root cuttings, 61
Stephanotis floribunda, culture of, 394
Sternbergia lutea, 481, 517; in Scotland, 504
 Stock, Virginian, for the autumn, 335
 Stocks, annual, cultivation of, 126
 Strawberries, planting, 395; seasonable work among, 169; the cultivation of, 353
 Strawberry season, how to prolong the, 430; St. Fiacre, 477; Tree, fruits of, 564
Streptocarpus and their cultivation, 363; culture of, 297
Streptocarpus cyaneus, 193; hybrid, 46
Styrax hemsleyana, 205
 Sun Roses, the, 231, 288; white, growing wild, 348
 Sunflowers, the perennial, 416
 Sweet Pea Jean Ireland, 354; National, Society's outing, 359
 Sweet Peas at Castlemilk, 360; best white, 92; cream pink, 167; for garden decoration, 77; from cuttings, 170; from cuttings and as standards, 127; new, 366; notes on some of the newer, 397
Syringa Juliana, 194; *Sweginzow*, 306
Tamarix anglica, 342
Taxus baccata fructu-luteo, 575
Thalictrum dipterocarpum, 493
 Thrift, a charming dwarf, 157
 Toad, the, in the garden, 372, 397, 408, 420
 Tomato plants diseased, 432
 Totley Hall, Derbyshire, 364
 Traveller's Joy, the, as a wayside plant, 592
 Tree leaves, 445
 Trees and shrubs as screens, 119; beautiful spring-flowering, 160; berried, 530

Trees and shrubs, deciduous, 380; evergreen, 380; snow on, 49; the best berried, 482; the use of variegated, 380
 Trees, early flowering, two beautiful, 145; our native, and their congeners, 593, 600, 615, 626; Japanese at Coombe Wood, 386; seedling, 575
Troilus chinensis, 37
Tropæolum speciosum, cultivation of, 68, 87, 111, 134; *tuberosum*, 610
 Tulip Bloodstone, 273; Bouton d'Or, 277, 312; Bread, 587; Comedy, 273; Empire, 260; exhibition and conference, 267; Inglescombe White, 273; *Raufmanniana*, 157; Marconi, 260; *Mirvana*, 280; notes, 164, 279, 289, 468, 485; Satin Gown, 273; show and conference, 215, the, in bygone days, 288; Winner, 260
Tulipa montana, 176
 Tulips, Darwin and Cottage, in the flower garden, 189; Darwin, the breaking of, 528; for forcing, 85; late-flowering, 555; May-flowering and Wallflowers, 327; species, in pots, 227; that flower in May, 508; trials of, at Wisley, 181
 Tweedia cærulea, 567
 Valerian, the Red, 54
Valeriana Phu aurea, 193
Vanda luzonica, 566
 Vegetable and fruit crops in Holland, 416; crops, spring manuring for, 117; crops, the desirability of late, 308; cultivating for present necessity, 155; cultivation, a pamphlet on, 193
 Vegetables exhibiting, 446, 468, 598; for sowing during August, 389; home grown, and our food supply, 63, 74, 86, 98, 110, 122, 133, 134, 146, 159; how to increase supplies, 81; insect enemies of, 239; large, 120, 266, 312, 337; large *versus* small, 288; notes on, 11, 46, 104, 165, 213, 261, 294, 332, 377, 384, 414, 446, 487, 535, 584; notes on, from seed, 128; quality in, 183; quality in, *versus* size, 206; storing for winter use, 469; the *Daily Mail* Show of, 480, 505; wanted, more exhibitors of, 443
Verbena chamædrifolia, 510, 528; *chamædryoides*, 354
Veronica Traversii, 383
 Veronicas, the, or Speedwells, 434
Viburnum plicatum in Hampshire, 384
Viburnums, the, or Guelder Roses, 336
Vinca difformis, 515
 Vine, a neglected, 511
 Vines, how to prune, 29; treatment of, in winter, 23; ornamental-leaved, 66
 Viola, a pleasing combination of, 287; *bosniaca*, 419; *bosniaca*, the hardness of, 456; *Papilio*, 265; *septentrionalis*, 273; *Rydbergii*, 455
 Violas, cultural notes on, 438; from layers and cuttings, 456; the yellow rock garden, 273
 Violets, Sweet, 569
 Virginian Speedwell, the giant, 259
Vitex Agnus-castus, 479
Wahlenbergia vincaeflora, 340
 Wall Bellflower, the, and Pinks, 223
 Wallflower and Tulip, a beautiful combination, 241; sowing seed, 189
 Wallflowers and their cultivation, 5; improved, 336; in pots, 135
 Wall garden, an inexpensive, 218
 Wall gardens, dry, 602
 Wall gardening, 17
 Walls, rock plants on, 349
 Wasps and fruit, 230, 266; destruction of, 456; war on, 206
 Water Elder, the, 469; gardening, 436; Lilies, planting the hardy, 198
 Watering, some hints on, 339
 Waterside, native plants for the, 401
 Wattle hurdles for shelter, 146, 170, 195

THE GARDEN.

No. 2250.—VOL. LXXIX.

JANUARY 2, 1915.

NOTES OF THE WEEK.

To Our Readers.—With this, the first issue of 1915, a new volume commences, and we take the opportunity of thanking our readers for their valuable co-operation and assistance so freely given in the year that has just closed. Interesting notes and photographs that have reached us week by week, often accompanied by letters of thanks and encouragement, especially since the outbreak of war, have been very highly appreciated, and those published have, we know, proved interesting and useful to an ever-increasing number of readers. A great many readers have also written for advice when confronted with garden difficulties, and it has been a pleasure to assist them in every possible way. Our thanks are also due to those who have supported our advertisers during the war. Nurserymen and seedsmen at all times have enough to do to make ends meet, and there is no doubt that they have suffered severely during the crisis.

A Beautiful Christmas Rose.—The flowers illustrated on this page are those of *Helleborus niger altifolius*, sometimes erroneously named *H. n. maximus*. It is, we think, the most beautiful of all the Christmas Roses, the large flowers being produced on stems a foot or sometimes more in height, and usually from two to six flowers on a stem. These are large, glistening white, with a beautiful rose pink blush on the more exposed parts, and often open during November and continue until well into January. The green flower and leaf stems are beautifully mottled dull crimson, and altogether it is as handsome and useful a hardy plant as one could wish for. Its value for cutting during the winter months is great, as the flowers last in good condition for quite three weeks when placed in water. We are indebted to Messrs. Barr and Sons of King Street, Covent Garden, for the flowers from which the illustration was prepared.

Olearia stellulata.—Some exceptionally large, well-flowered bushes of this fine shrub—the whole constituting one great colony—were noticed in flower last autumn in the gardens of the Horticultural College, Swanley, where in the loamy soil over chalk it appears to be perfectly happy. The plants were 5 feet or so high, the white, starry flower-heads arranged in terminal racemes so abundantly as to almost cover from view

the elegant habit of the subject. Occasionally we read of its tenderness, though in the gardens mentioned it has stood for years without a stain upon its character.

Dates of Horticultural Shows.—Owing to the war, so many committees of horticultural societies have not found it possible to fix the dates of their shows for 1915. Under these circumstances we do not consider it advisable

cultural Society, Mr. Chittenden showed an Apple with ten longitudinal grooves of about a quarter of an inch deep on the outside, the grooves being lined with russet. He called attention to the small fruits damaged internally by frost, which he exhibited earlier in the year, and pointed out that the grooves corresponded with the position of the primary vascular bundles which had been injured by frost. These bundles in the specimen

exhibited still showed signs of the damage, and the failure to grow normally was no doubt due to the interference in the sap flow brought about by this injury.

An Attractive Plant for the Bog Garden.—The majority of people are familiar with the well-known Creeping Jenny (*Lysimachia Nummularia*) and its decorative value for many situations, but few know Henry's Loosestrife (*Lysimachia Henryi*), a charming evergreen species from North-West China and of recent introduction. During the summer it is one of the most beautiful plants in the bog garden, where it delights to ramble about over the damp, cool soil in full sun, branching as it grows, bearing its golden yellow, cup-shaped flowers in large clusters almost hiding the plant, and remaining in bloom for a long time. As a carpet to *Lobelia fulgens* it is very effective. It appears to be perfectly hardy, and is very easily increased by cuttings put in now, by seed, or by divisions.

Fraudulent Booksellers.—The British Gardeners' Association is bestirring itself over the fraudulent booksellers who seem to have been particularly active of late. The usual procedure is for a traveller to call on young gardeners and induce them to pay a sum ranging from 5s. to a guinea as a first instalment for some important gardening work; or else, on the understanding that the vendor will send the whole work, which he has been able to obtain cheaply, for about a quarter of its value. Needless to say, the books never reach the young gardener, nor does he see the plausible

HELLEBORUS NIGER ALTIFOLIUS, ONE OF THE MOST BEAUTIFUL OF ALL THE CHRISTMAS ROSES.

to publish our usual almanac in which we have hitherto given the dates of the principal exhibitions. These will, however, as far as possible be published each week under the heading of "Forthcoming Events." We shall be glad if secretaries will kindly send us dates, when decided upon, for that purpose.

Frost Damage to Apple.—At the last meeting of the scientific committee of the Royal Horti-

cultural Society, Mr. Chittenden showed an Apple with ten longitudinal grooves of about a quarter of an inch deep on the outside, the grooves being lined with russet. He called attention to the small fruits damaged internally by frost, which he exhibited earlier in the year, and pointed out that the grooves corresponded with the position of the primary vascular bundles which had been injured by frost. These bundles in the specimen exhibited still showed signs of the damage, and the failure to grow normally was no doubt due to the interference in the sap flow brought about by this injury.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Banksian Roses.—If in what I wrote you about Banksian Roses, page 604, issue December 19, I said Fortune's Yellow, it was a slip. I meant Fortune's Banksian.—F. G. DUTTON.

Soldanella in Bloom in London Metropolitan Area.—You may be interested to know that a plant of *Soldanella alpina*, which I collected in the Alps when on a holiday in June, 1913, is now proudly showing two nodding mauve bells in my garden here. You will note that the vagaries of our climate have been too much for the *Soldanella* clock, for it evidently has mistaken the dry autumn for an alpine winter, and the present torrential showers for February "fill dykes." I

grow in almost any good garden soil, and the position, so long as it is open, does not matter much. They must, however, have ample space in which to develop. The plant illustrated was nearly two feet in diameter. One of the most charming garden pictures I have ever seen was composed of these pink Mallows growing between white Japanese Anemones, and I pass on the hint for others.—A. B. ESSEX.

Cuttings with Heels.—This is a very interesting subject. I fully agree with your correspondent "H. P.," page 594, issue December 12, in his remarks respecting cuttings severed just below a joint in the case of soft-wooded plants. Such cuttings root freely, and make rapid growth afterwards. Few cuttings of this kind inserted in August and September in cool soils, and in spring or even late in the winter in a gentle bottom-heat, fail; but I prefer in the autumn to put in

of the cult. If you require a mildew-proof *Rose*, plant *Gloire de Dijon*. Perhaps someone has seen this old friend badly mildewed; if so, let us have particulars.—JOHN W. HICKS, 4, Wellington Terrace, Sutton Coldfield.

Funkia subcordata alba odorata.—Some three years ago, in September, a London firm exhibited in Edinburgh a plant of this *Funkia* in flower. The plant attracted me, being the only pure white *Funkia* I had seen. Its fragrance and its late flowering also weighed with me, so I purchased a plant. Judge of my disappointment, however, when I say that, though I planted it under conditions where *Funkias* and hardy plants generally thrive well, it has not yet produced a single bloom, and, instead of developing, the plant has hardly held its own. I should be glad to know if any other readers of THE GARDEN have tried this Plantain Lily, and, if so, with what result.—CHARLES COMFORT, Midlothian.

Ginkgo biloba or Maidenhair Tree.—It was good to see an illustration of this unique tree in the pages of THE GARDEN, in which you did well to call attention to its ornamental qualities and its distinct nature. With regard to this latter feature it stands out quite alone, for there is not a single tree in cultivation that can for one moment be compared with it. The popular name of the Maidenhair Tree is a very appropriate one, as the leaves greatly resemble in shape the pinnules of that popular Fern. The scientific name of *Ginkgo* cannot, however, be viewed in the same light, for it is at best such an awkward sounding word as to lead one to think that *Salisburia adiantifolia* would have been much the better. Great interest is attached to this *Ginkgo*, from the fact that though it now stands quite alone, yet fossil remains have been discovered in systems that were in process of formation at a remote epoch of the earth's history, and which serves to prove that the genus is of astonishing antiquity and that the first appearance of its ancestral form antedates that of any other existing tree by countless ages. It has long been cultivated by the Chinese and the Japanese in the neighbourhood of their temples, but it does not appear to have been discovered anywhere in a wild state. A notable autumn feature in this country is the clear yellow tint assumed by the decaying leaves.—H. P.

—The illustration of this tree in THE GARDEN for December 19, page 607, does not present the characteristic form and is taken from a small inferior specimen. There are, at Cobham Hall, Gravesend, two specimens, either of which is nearly three times the size of the Kew example illustrated. The branches are semi-drooping through their whole length; many lie on the ground and turn up at the points. The trees are about a century old. They are in a private part of the pleasure grounds, and could only be seen by permission. It would be interesting to see an illustration of them. The *Ginkgo* has never been found wild. It is a survival, and almost a sole survival, from early carboniferous ages; but its distribution is a geological question of much difficulty. There is no doubt it owes its curious leaf to existence in an age when evolution had not attained to the rounded or curved leaf. The specimens at Cobham are believed to be surpassed by very few in the world.—KURSTOOT.

How to Plant *Crinum Powellii*.—In answer to "Enquirer," the above plant grows vigorously and flowers every year with us; while last summer an old bulb eclipsed all previous efforts by yielding three consecutive large spikes. We grow this

A SINGLE PLANT OF PINK MALLOW, A VERY BEAUTIFUL HARDY ANNUAL.

am endeavouring to keep up the illusion as long as possible by protecting the treasure by means of a "Sunbeam" Trap.—JAMES LATHAM, Hurstwood, Woodford Green.

Pink Mallows for Summer and Autumn Effect.—Although the pink Mallows are among the most useful and beautiful of all hardy annuals, one does not find them in many gardens. Why this should be so I have never been able to understand; and now that seeds will soon be ordered, the accompanying illustration will, I hope, induce many other readers to include in their list an order for a packet of seed. The plant illustrated was one of a hundred or so that were raised from seeds sown in the open the first week in April last year, and from the middle of June until well into September they gave us a wonderful display of their pink or rose coloured blossoms. For cutting we found these ideal. So far as my experience goes, these Mallows will

cuttings of *Roses* and many kinds of evergreen and deciduous shrubs which possess a slight heel. If properly inserted and attended to, they result in very fine, sturdy specimens.—SHAMROCK.

Mildew-Proof *Roses*.—Having found that certain *Roses* are attacked by mildew in one locality and immune in another, that in some soils the pest is more prevalent than in others, and that newly planted *Roses* are less liable to an attack than established plants, there is nothing more to say except that the grower whose enthusiasm does not carry him sufficiently far to spray once a week with Abol or some other preventive—if there is one—had better leave the ranks of the faithful and take to *Chrysanthemums* or *Carnations*, or might I suggest *Sweet Peas*. Spraying once a week is one of the pleasures of *Rose* culture. What credit is due to a rosarian who has no pests to overcome, no difficulties to surmount? These very difficulties are the zest

Crinum on a west border, and the planting was from 4 inches to 6 inches deep. The first three or four years after planting, a small mound of ashes was placed around the dying neck of the plant when a frosty spell seemed upon us; but during the last two very moderate winters no protection has been given. Of course, we should not take needless risks if severe weather threatened, though it is my opinion that this plant is hardier than has been supposed, and I would venture to assert it would come safely through any winter uncovered, with shallow planting, if the situation is warm, non-clayey and well drained. Ours is a made-up border, and cannot boast of more than 18 inches to 20 inches of good soil; below that depth it is clay, and no doubt our plants have reached it. The very deep planting advised by some authorities may be due to the fact that there has been some doubt about the hardihood of this Crinum, and assuredly deep planting would minimise winter risks. Mr. Van Tubergen's directions, though seemingly at variance with others, may probably be followed with equal success, for they are at one with the advice that used to be given by an acquaintance of mine in the catalogues of a firm now no more. His directions were: Plant in a hot place, leaving one-third of their length out of the ground, but give plenty of water in summer and protection with Bracken, &c., in winter. To sum up, it is plain that shallow planting means more water in summer, more covering in winter; deep planting, less water and less or no covering.—C. T., *Ken View Garden, Highgate.*

— From experience I can assure "Enquirer" he need have no misgivings if he has followed the directions of that gardeners' *vade mecum*, Robinson's "English Flower Garden." For the last twenty-five years I have seen Crinum *Powellii* grown to perfection deeply planted in the garden of a relative, and even in my own wretched Surrey sand I have grown plants thus with some success. It is important to remember when planting deeply to give a good depth of rich soil under the bulbs. In winter I cover the clumps with a foot of ashes; this is removed in the spring and the plants mulched. They have withstood 30° of frost. They should be well watered continually in the summer and occasionally given liquid manure. If "Enquirer" would obtain the results he has seen at Burford, I would advise him to have patience and wait, and if he has planted his bulbs properly, on no account to interfere with them, but leave them to establish themselves, which may take a few years.—C. B.

Hardiness of Cyclamen persicum.—I think it is usually considered that the Persian Cyclamen is a tender subject, and certainly I have hitherto had that impression. Now I am not quite so confident. Having between two and three dozen surplus plants this autumn, I placed them in a small cold frame and thought no more about them until December 7, when I wished to have the pots emptied and housed. On looking into the frame, every plant was perfectly fresh and healthy, although on several occasions we registered 10° of frost, and no protection other than the sash was afforded. I have retained three of the plants to note how they will now thrive in a greenhouse.—C. BLAIR, *Preston House Gardens, Linlithgow.*

FORTHCOMING EVENT.

January 5.—Royal Horticultural Society's fortnightly Meeting and Exhibition, Vincent Square, Westminster, 1 p.m. to 6 p.m.

SOME HARDY LILIES.—I.

OF all the plants cultivated in British gardens, there is no genus in which so much disappointment is incurred—none upon which so much money is wasted—as the Lilies. If there were no remedy for this—if these plants were really intractable—then the only sound advice to be offered to the amateur would be to leave them alone. But whereas the nature of the mischief which wrecks so many hopes requires only to be understood in order to overcome it, the following notes are offered by one who, having undergone repeated failures during long years of endeavour, has been led by the counsel of an experienced friend into the path of success with some species.

The difficulties in cultivating Lilies arise mainly from two sources. First, although the genus is a small one compared with many others, containing, so far as is known at present, only between seventy and eighty true species, these species exist in a natural state under widely differing conditions of soil, temperature, moisture, exposure, &c.; wherefore any attempt to cultivate them must end in disappointment, unless provision be made to meet their requirements in those respects. Secondly, with the exception of a few species long established in this country, such as the Madonna, the Orange, the Tiger and the common Martagon Lilies, the vast majority of bulbs offered for sale have been imported from distant lands, and arrive in such a condition of impaired vitality as renders them most vulnerable by disease or decay. The rootlets, delicate in some species, fleshy in others, either have been deliberately shorn off by the packers (as is usually done to bulbs exported from Japan), or have dried up and become functionless during transit. Each year tens of thousands of Lily bulbs, purchased in this enfeebled state, either are planted in the autumn in the open border, where they are expected to survive the drenching of a British winter, or are bought at the spring sales and set out at once to provide a summer display. Such treatment of dormant bulbs ensures disaster. Of those planted out in the autumn, many are never seen again; they simply rot in the ground. Those that survive may throw up flowering stems from material garnered under a foreign sun; but in nearly every instance it is a swan song. In the second season their place will know them no more.

The only chance of prolonging the lives of imported bulbs is to treat them as invalids, keeping them in hospital during six months or a year after their arrival. On no account should they be planted out in the open at once. Each bulb should be placed in a 6-inch or 8-inch pot and kept in a cold frame till the pot is full of new roots. Imported bulbs, especially those from Japan, are too often infested with mites, or with the deadly fungus *Rhizopus necans*, to destroy which they should be dipped in a 1 per cent. solution of salicylic acid and dusted with sulphur before potting. Some charcoal or wood-ashes should be laid over the drainage before filling the pot three-quarters of its depth with soil suitable to the species, mixing in ground lime for those that like it, and scrupulously withholding it from those that dislike it.

Bulbs treated in this manner after arriving in the autumn will probably be found in the following May to have sent up more or less vigorous shoots. This behaviour on the part of base-

rooting Lilies—that is, Lilies which send out roots only from the base of the bulb, like the common Orange Lily, *L. croceum*—is a sign that they have benefited by the rest. If, therefore, the pots are found to contain fresh, healthy roots, the bulbs may be planted out carefully in the place where they are intended for permanence; and, be it remembered, permanence is of cardinal importance in Lily culture, all species more or less resenting disturbance, some of them intensely. Do not be disappointed if the display in the first season of flowering comes far short of expectation. The bulbs have passed through the crisis of removal, which imposes a severe strain on their vitality; indeed, prudent gardeners will not allow the more sensitive species to flower in their first season, but will remove the buds so that the whole stream of nutriment shall be diverted to the bulb. This sacrifice of a year's blossom will ensure ample compensation in following seasons.

Stem-rooting Lilies—that is, Lilies which, like *L. auratum*, send out roots around the base of the stem as well as from the base of the bulb—require more cautious treatment. The appearance in spring of a strong shoot sent up from a bulb potted in the previous autumn must not be interpreted as proof that the Lily is ready to take its place permanently in the open. If the contents of the pot be carefully turned out, it will probably be found that such roots as it contains are those sent out from the base of the new stem only, and that there are no basal roots whatever, showing that the bulb is expending the material gathered in the previous summer, without replacing it with fresh nourishment. The stem will grow, fed primarily from the bulb, and secondarily by the roots it has itself sent out. There will be a fair, perhaps a fine, display of blossom; but when that is over and the stem dies, the bulb will have disappeared. The only safe treatment, therefore, of stem-rooting Lilies in their first season is to fill up the pots with soil, plunge them in the open air in a place where the bulbs will be protected from scorching sun, and remove the flower-buds so soon as they become visible. Drastic discipline this, and to the amateur accustomed to deal with such facile subjects as Narcissus, Crocus and the like, all these preliminaries may seem fussy and superfluous; but in the treatment of Lilies success with this matchless genus brings a reward rich enough to indemnify one for extraordinary trouble.

Having experienced the usual result of unintelligent attempts to coax certain Lilies into permanent vigour, having met with much discouragement and failure, and, after many seasons, been led to see the error, or some of the error of my ways, I can perhaps help other amateurs by explaining what are the chief faults to avoid in managing those species with which I have succeeded. I shall only presume to write about those Lilies of whose behaviour I have had personal experience, either in my own garden or the gardens of my friends. There are many species which I have not yet ventured to handle. About these I must keep silence, referring readers to the invaluable cultural treatise on the genus by Mr. A. Grove—"Lilies," by A. Grove (Present-day Gardening, London: T. C. and E. C. Jack, price 1s. 6d.)—who, had his lot been cast among an Oriental people, would assuredly have been known to them as the Father of Lilies. In his garden near Henley I have seen the delicate novelty *L. Kelloggii* and *polyphyllum* growing with the grace and flowering with the freedom of a common

Martagon, the stately *L. Parryi* swinging its golden bells on wands 5 feet and 6 feet high, besides other fastidious foreigners which are doomed to perish inevitably under less sympathetic and experienced hands. What follows, then, is far from being a comprehensive review of the genus; only a notice of some of the more desirable species, with suggestions as to their management. HERBERT MAXWELL.

(To be continued.)

LIVING PESTS IN DAFFODIL BULBS.

I WAS very glad to see last autumn, in one of the ordinary Daffodil lists, a few words of warning from the pen of Mr. Charles E. Shea, who, although best known to our readers as a great rosarian, is, nevertheless, a grower of Daffodils of no mean order. His scientific leanings have led him to watch the varied pests to

I refer to *Eumerus lunulatus*, which at present not only troubles the stomachs of the plants, but, according to some vigorous letters which appeared not a hundred years ago in the pages of a famous and learned gardening paper, the heads of the unfortunate growers as well. Then there is the caterpillar of the swift moth (*Hepialus lupulinus*), which seems to have a partiality for the young roots, which it devours, at the same time often taking a bit out of the bulb as well. This beast, although it is the largest enemy, is the one that gives us the least concern, for it is not a very widely spread or frequent visitor. I am rather disposed to say that the living pests are to be feared in the inverse ratio of their size. Thus, first, the aforesaid caterpillar. Secondly, the merodon, which is not very dissimilar on the wing to a drone fly or a honey bee, did not the curious whistling noise and the lightning dashes of its flight unmistakably mark it—rather should I have said the merodon grub, for it is this dirty white, fat, black-

sive, and Mr. Shea is a lucky man if his beds are immune. Possibly he did not mention it because he considered it to be a scavenger that only appears when something else has done all the damage—when, it may be said, its presence is rather a blessing than a curse; but about this I have my doubts. Fifthly, and lastly (as I am not going to talk about an animal that worried Mr. Selkirk's bulbs at Sydney last year; for enough is as good as a feast, and without bringing this into my pot-pourri of living pests I will have enough to say), there is *Tylenchus devastatrix*, which, notwithstanding this mouthful of a name, is a diminutive eelworm only a twenty-fifth of an inch long, and of slender proportions and build, but which, I am disposed to think, is the most to be feared of all the living crew that I have enumerated. Although it is said by some observers to be only a scavenger, I am almost certain that this is not so, for the tiny worm seems to attack firm, healthy bulbs, entering, as a rule, from the top and

working its way down the leaf courses until it eventually gets to the basal plate, which is, to the family's taste, the tit-bit of the bulb. I have submitted samples more than once to two independent experts, thinking that their report would be "*Fusarium bulbigenum*." But no; every time, "No trace of *Fusarium*, but plenty of eelworms." Both the Board of Agriculture and Fisheries and the Department of Agriculture and Technical Instruction for Ireland have issued leaflets on this eelworm; but whereas the former only incidentally refers to its presence in "Hyacinths and other flower bulbs" as well as in Onions, the latter is headed "Eelworms in Narcissus Bulbs." It contains the result of elaborate trials between October, 1912, and November, 1913, the objects of which were to (1) determine whether infection takes place in the soil or when the bulbs are stored; (2) its method or means of entrance; (3) how they may be killed without injuring the bulbs; and (4) how attacks may be prevented. The pamphlet is a long one; but without traversing all the ground which it covers, the results may be summed up as follow: By treating lifted

LILIIUM AURATUM IN A BED OF LOW-GROWING EVERGREEN SHRUBS.

which, alas! this flower is now, as it were, the heir with a thoroughness and interest which are not given to everyone. Hence his cry of "Wolf!" is one to which I respectfully urge my fellow-growers to pay the greatest attention. As he reminds us, it was once upon a time perfectly true to say that the Narcissus had but "one insect and one disease" to contend with. To-day, however, it would only be a "Turkish wireless" that could make such a statement. It is, I very much regret to say, quite as bad as that; for there are five living beasts who have found the Daffodil bulb in one state or another a toothsome morsel, and who seem to be able to impart to succeeding generations of their families their acquired taste. These are Merodon equestris, as I suppose we must begin to call the large Daffodil fly, since within the last few years another winged beast of lesser proportions and of quite different ways has begun to make serious attacks upon our bulbs.

ended beast that does all the damage, because he will at the same time make a house and a meal of any Daffodil bulb that he comes across, and his mother takes care that there is always one at hand when he is born. Thirdly, there is the small Narcissus fly, or, as it is generally spoken of, the Eumerus. This is like a small, square-headed and square-tailed—if I may use such an expression—house-fly, almost black in colour, a low-flyer and fond of taking fairly long rests on the leaves or the ground hard by, when, I presume, the eggs are laid, which in time become small-looking merodon grubs, only known to us, I fear, when they (for there are a good many as a rule) have taken possession of a bulb. Fourthly, there is the mite—a small, almost transparent, white animal, built up of circles like the man in the advertisement of Dunlop tyres—ivory white in colour, with two black spots on the back. I am afraid this beast is becoming increasingly aggres-

sive, and Mr. Shea is a lucky man if his beds are immune. Possibly he did not mention it because he considered it to be a scavenger that only appears when something else has done all the damage—when, it may be said, its presence is rather a blessing than a curse; but about this I have my doubts. Fifthly, and lastly (as I am not going to talk about an animal that worried Mr. Selkirk's bulbs at Sydney last year; for enough is as good as a feast, and without bringing this into my pot-pourri of living pests I will have enough to say), there is *Tylenchus devastatrix*, which, notwithstanding this mouthful of a name, is a diminutive eelworm only a twenty-fifth of an inch long, and of slender proportions and build, but which, I am disposed to think, is the most to be feared of all the living crew that I have enumerated. Although it is said by some observers to be only a scavenger, I am almost certain that this is not so, for the tiny worm seems to attack firm, healthy bulbs, entering, as a rule, from the top and

FOUR GOOD WALLFLOWERS:

Yellow: Yellow Phoenix.

Purple: Ellen Willmott.

Red: Fire King.

Crimson: Blood Red.

It only remains now for me to suggest means of how best to combat the other four pests. The mite may be dealt with in the same way as the eelworm. The caterpillar must be searched for by digging up bulbs which have failed to appear above ground or where the foliage remains stunted and unhealthy-looking. Both the flies may be trapped by nets during periods of sunshine in the warm days of May, June and July. (A sharp lad soon learns to detect and catch them; but the work must be done daily.) As a further means of catching them, every bulb before planting should be carefully felt all over, and if any part seems suspiciously soft, that bulb should be cut open and examined. In expensive varieties this must be done very cautiously, as it is often possible to save a bulb, or, at least, part of it. I am doubtful if immersion in water before planting does any good. I have never tried it myself, for, I am thankful to say, we have but very few, and the net and examination by feeling the bulbs have always proved efficacious. There is a good account of Merodon equestris in the Royal Horticultural Society's "Daffodil Year Book" for 1915, which everyone interested in the subject should read.

JOSEPH JACOB.

COLOURED PLATE.

PLATE 1503.

WALLFLOWERS AND THEIR CULTIVATION.

DURING the next week or two gardeners will be busy compiling the list of seeds to be sown during the coming spring and summer, and it is to be hoped that none will be minus a few packets of Wallflower. It has been a favourite in our gardens for many years, the fragrant blossoms appealing to us more strongly than many of more garish colours that do not emit fragrance worthy of the name. Fortunately, the Wallflower is easily cultivated, and a packet of seed will, if properly treated, provide several hundreds of sturdy plants. Although strictly a perennial, the Wallflower is usually treated as a biennial, *i.e.*, the seeds are sown one year to provide flowering plants for the next, and after the blossoming has ceased these are discarded. Where, however, they are more or less naturalised on rock-work or old walls, the plants are allowed to remain for many years, and treated in this way they are quite in keeping with their surroundings.

It does not seem to be generally known that there are two distinct sections of the Wallflower, one characterised by the Early Paris type, and the other by the ordinary Blood Red, such as may be found in many cottage gardens throughout the country. The Early Paris Wallflowers should be sown outdoors early in April, and the seedlings pricked off 10 inches or rather more apart as soon as large enough. These are subsequently best left alone, and if the fates are kind they will commence to flower in August and continue all through the winter. For several years we have

been able to gather quite good blooms on Christmas Day. Although the flower-spikes are rather small, the blossoms possess the true Wallflower fragrance and they are obtainable in yellow and warm brown colours. Midway between these and the ordinary Wallflowers comes Yellow Phoenix, so well portrayed in the coloured plate presented with this issue. It does not commence to flower so early as the Paris types, but in a mild winter can be had in bloom at Christmas if the seeds are sown in April. It is a great improvement on the Paris varieties, inasmuch as the flowers and spikes are much larger and the plants bloom freely in spring, long after the others have finished.

When we come to the ordinary May-flowering varieties, such as Blood Red, we find some diversity of opinion as to the best time to sow the seed. Some good gardeners favour April, and others, equally as good, the second week in June. If the happy medium between these two is selected and the seeds are sown about the second week in May, good results may be anticipated in nearly all districts. Outdoor sowing, in drills 1 foot apart, is best; and as soon as the young plants are about two inches high they ought to be transplanted, 1 foot apart each way, in soil that is moderately good but not over-rich and which has been trodden fairly firm. With the advent of early October, when spring bedding has to be arranged, the plants can be lifted with good balls of soil and roots and planted wherever they are required to flower.

There are now a good many varieties to select from. In brown shades Harbinger and Vulcan are good; Blood Red for crimson; Ellen Willmott, purple; Yellow Phoenix and Belvoir Castle,

SWEET LAVENDER IN THE GARDEN.

IT is impossible to conceive an English garden without Lavender. One never makes a new garden without using it in some position, and the situations in which it can be grown with advantage are numerous. An old garden without it would lack an essential charm. It is one of the few plants that can survive the ignominy of being common in these days of perpetual craving for novelty; indeed, it is among the few that are sought after because they are common. In its way it is as essential as grass and paths, and to every garden-lover it conjures up a picture, perhaps of an old-world garden we used to know with its Pinks, Sweet Williams, Madonna Lilies, Cloves and Moss Roses; or of some delightful old thatched cottage where Jasmine, Honeysuckle and Eglantine entwined over the doorway; or, indeed, of quiet hours in country houses where from January to December its fragrance permeated the snowy whiteness of household linen. Its popularity is not to be wondered at when one considers its many attractions — delicious fragrance, easy culture, hardy enough to withstand the severest winter, a colour that attracts most people and repels none, and cool, grey foliage that can be used indiscriminately everywhere and in association with anything, and at no time of the year ugly.

Quite apart from its value for perfumery, its garden uses are numerous. No plant is more

A BORDER FILLED WITH WALLFLOWERS IN THE GARDENS AT LOCKINGE, BERKS.

yellow; and Fire King, red. The last named is comparatively new, and is one of the most beautiful Wallflowers that we know. All the flowers from which our coloured plate was prepared were kindly supplied by Messrs. Sutton and Sons from their trial grounds at Reading.

valuable in the herbaceous border, where it can be made the groundwork of many delightful colour schemes. A group of *Lilium candidum*, Lavender and pink *Antirrhinums* is particularly effective; or *Erigeron Quakeress*, *Pentstemon Myddelton Gem* and a dwarf Lavender, with

Campanula carpatica Riverslea and *C. persicifolia alba*, forms another pretty combination.

For clothing banks that are on the dry side it is equally useful, and can, if desired, be kept trimmed down to a smooth, even surface, providing it is cut at the right time; early September is the best, as it gives it time to make sufficient growth to look neat all the winter, and with most varieties the flowering period is nearly over by that time. For low hedges it is also useful, particularly where a sense of division rather than seclusion is necessary. Used as an edging to long, broad borders it makes an excellent foil for taller subjects behind, and, trimmed once a year, remains quite neat without getting too rigid in appearance, the dwarf forms being best for this purpose.

The Best Kinds.—The nomenclature of the varieties at present in cultivation appears to be a little undecided and to lack authority; indeed, we find the same thing cropping up under half a dozen different local names and, worse still, several distinct forms bearing the same name. They have all probably originated as seedlings from the two species described in an old gardening dictionary published in 1736, as follows: "*Lavandula Spica*, the common lavender, closely branching from bottom 2 or 3 feet high, small spear shaped entire leaves, and from the ends of the branches numerous, long erect naked spikes of flowers, various shades of colour white to blue." The broad-leaved form is described as the species. There are two varieties given as with narrow leaves, blue and white, the narrow-leaved varieties being described as "in greate esteem for putting among cloaths, and distilling and other oeconomic uses." There is also a dwarf form of the broad-leaved species described, which is probably that shown in the accompanying illustration, and now known as *Lavandula Spica nana compacta*. The only other species described in the old book as for out of doors is the French Lavender (*Lavandula Stœchas*), very branching, 2 feet or 3 feet high, very narrow, spear-shaped leaves, pointed and hoary, opposite, and all the branches terminating in short, bushy spikes of purple flowers. There is also a white variety.

With reference to those now in cultivation, there appear to be three species—*Spica* and *Stœchas*, originating in the Mediterranean regions; and *vera*, common to Southern Europe, *vera* and *Spica* resembling each other except in the breadth of the foliage, that of the latter being broadest. For some reason the broad-leaved is usually offered as English, the narrower-leaved as Dutch, the dwarf form of *Spica* as *nana compacta*; while a low-growing, compact, narrow-leaved variety is commonly called dwarf blue.

The broad-leaved is much the best for hedges or permanent edgings, as it retains its foliage well throughout the winter. The narrow-leaved form is inclined to get shabby and

thin through the winter, but recovers well with the growing season and flowers longer. The foliage is very grey.

Two recipes for Lavender water are: One pint of rectified spirit, 4oz. of distilled water, 3 drachms of oil of lavender, 3 drachms of orange-flower water, 5 minims of oil of cloves, the same quantity of oil of cinnamon, and 4 minims of otto of roses mixed and allowed to stand for twenty days; then filtered through magnesium carbonate and kept two or three months in bottle before using. The other is: Essence of musk, 4 drachms; essence of ambergris, 4 drachms; English lavender, 6 drachms; oil of geranium, 2 drachms; oil of cinnamon, 10 drops; and spirits of wine, 20 oz.

LAVENDER AS AN EDGING TO A PATHWAY IN MESSRS. R. WALLACE AND CO.'S NURSERY.

An old recipe for Lavender bags is: "Take of ye lavender flowers a full half a pound, but no stalks therewith. Of dried thyme and minte a half an ounce of each, and of common salt one ounce, together with one ounce each of ground cloves and carraway seeds. Mix quite dry and put in silk bags, and it will perfume the drawers and linen very nicely." Doubtless there are a number of other old recipes in existence, and it would be interesting if those readers who have them would send them to the Editor for publication. We cannot have too much information about this fragrant shrub, which, I think I may safely say, is a universal favourite.

G. D.

FLOWERS IN THE KITCHEN GARDEN.

THE practice of growing hardy flowers in the kitchen garden has been very largely extended during recent years, and in most good establishments we now find the main pathways of the vegetable quarters bordered on either side with bold masses of herbaceous and other hardy plants. Indeed, in some kitchen gardens that I have seen during the last year or two, the flower borders were scarcely inferior to the herbaceous borders proper, and lent an air of calmness, beauty and interest to a portion of the grounds that was wont to be considered dull and not worthy of visitors' attention. Undoubtedly the primary reason for cultivating flowers in the kitchen garden was to provide plenty of material for cutting, so that the dwelling-house might be well and freely decorated; but by devoting the borders alongside the pathways to the plants, a twofold object is achieved. Flowers in abundance are always available for cutting, and, as already stated, the kitchen garden is rendered beautiful and more interesting than it would otherwise be.

Frequently these flower borders are arranged in front of espalier fruit trees that enclose the vegetable plots, and where this is so, some care needs to be exercised in planting the flowers, otherwise the fruit trees will suffer. Thus, very tall and coarse-growing plants would not be permissible, nor would it be advisable to plant within 18 inches or 2 feet of the fruit trees, unless no value is placed upon the fruit. In some few gardens the trees are old and are retained solely as a screen, their flowers in spring adding a touch of colour to the borders. In such instances they need not be taken seriously into account when planting the herbaceous flowers, though it must even then be remembered that the roots of plants and trees will contest strongly for the nourishment that the soil contains. The most important point to bear in mind when forming flower borders in the kitchen garden is their width. This will, of course, vary considerably with the length of the path; but, even with the shortest pathway, a border less than 5 feet wide will not be of much service. When it must be of less width it resolves itself into an edging, and should be treated as such, a broad belt of some hardy annual or low-growing perennial being all that is permissible. Generally, however, a border 8 feet wide is a useful size, though where the pathway is a very long one, and the ground can be spared, it may extend another 2 feet. In borders of these widths nearly all kinds of

herbaceous, bulbous and annual flowers may be successfully grown, the actual kinds being usually determined by the material available. The good gardener will see to it that those most useful for cutting will predominate, any that are not suitable for this purpose being merely used for filling temporary gaps or as low-growing vegetation for the edges of the borders.

At Aldenham House, where grass verges used to edge the flower borders in the kitchen garden, they have been replaced by a rough stonework edging, medium-sized pieces of sandstone being sunk into the ground so as to form excellent

a good deal of heavy work has to be undertaken in the kitchen garden. For this reason, except in gardens of large size, such arches are best kept to the pleasure grounds. Rose pillars are, however, suitable for the kitchen garden flower borders, though even these must not be overdone.

In a few gardens annual flowers only are used, so that the borders are practically free of vegetation during the winter months when heavy work, such as the wheeling in of manure or new soil, is in progress. There are now so many good annuals available that it is not difficult to create a pleasing effect with them alone, though where preference

LATIN NAMES AND GOOD RESOLUTIONS.

AS another New Year has just dawned, the time arrives for making new resolutions. To the gardener the period of short daylight hours and sodden or frozen flower-beds is peculiarly well adapted for thinking over past—well, we will not say *failures*, but—performances that have not come up to our expectations, and for thinking out new and fascinating schemes. This year it is an occupation full of novel—let us hope

FLOWERS BORDERING A PATHWAY IN A KITCHEN GARDEN.

little pockets for many kinds of alpines. Not only is the effect pleasing, but the pathways are rendered exceedingly interesting over many months of the year. The stone is almost hidden by the vegetation, which is allowed to scramble over on to the pathway and so avoid any impression of formality. This informality of edges is well shown in the accompanying illustration, though in this instance stonework is not used.

In many gardens rustic arches, clothed with Rambler Roses or Clematis, are placed over the pathway, and, if properly situated, add considerably to the beauty of the garden as a whole. But such arches must be of a lofty and broad character, ever bearing in mind that during the winter months

is given to the old-fashioned kinds, such as Mignonette, Honesty, Larkspurs, Stocks, Marigolds, Sweet Alyssums and Clarkias, the borders are endowed with greater interest, the fragrance of many of the flowers being not the least item in their favour.

The extent to which these flower borders may be varied will rest more or less with the taste of the owner, always bearing in mind that they are an adjunct to, rather than a part of, the kitchen garden itself. If this is fully remembered, there is no reason why the kitchen garden should not be made far more interesting and beautiful than is usually the case. This is especially so where there is ample space available.

H.

we may say unique—difficulties. Those who cannot leave gardens and homes for active service must feel it is their duty to keep business running as usual during alterations to the map of Europe, in horticultural as well as other affairs.

Even though dividends dwindle or remove themselves to still distant years, as though looked at through the wrong end of the telescope, one of the best resolutions is to guard against making the struggle harder for others. We may do this by trying to prevent both the cancelling of orders to nurserymen and the discharging of gardeners in our employ. We can make a virtue of necessity, and take some credit for foregoing our usual spring order for rare rock plants from Bavaria or new

seeds from Erfurt. Perhaps we feel we must give up our plans of a summer collecting trip in Tyrol or elsewhere, and thereby be able to reckon that the amounts thus saved can be expended for the benefit of the nurserymen and gardeners of our own country. But even if we cannot lay out a penny on plants this year, we can still find scope for a good resolution or two in work among the plants we have. Do not let us be put off by the cynics who tell us hell is paved with good intentions; rather let us reason that it could only be broken ones that would be suitable for the purpose, and rely on other authorities on the nature of that place who assure us it is a bottomless pit, and therefore cannot require much pavement; and, better still, feel assured that no good gardener will ever find himself there.

Therefore I suggest that we should all employ our gardening wits and time this year in learning more about the names of plants, and trying to have all those in our gardens as correctly named as possible. The result of this should be twofold, a twin fruit like that of an Asclepiad—first, on the labels in the borders, and, secondly, in our garden catalogues. It is not an easy task to carry through, but a wonderfully interesting and improving one. Not only is there no royal road to the desirable goal at the end of it, but I know of no concise, popular book devoted to the subject of the nomenclature of plants.* This is a pity, as so many people who are fond of flowers and gardens find great difficulty in learning and remembering the right names of their favourites. "Latin names are so difficult, so ugly or so meaningless," they say. "Can't you give it an English name?" A good friend of mine had a delightfully simple plan for curing such a desire in friends to whom he was showing his plants. When they objected to his naming them in Latin, he would give them a nice simple name for each according to its colour. "That is the blue flower," he would say, and his visitor would beam, and answer, "Now, I call that a sensible name." But when she (it was most frequently one of the fairer sex) had beamed and purred contentedly over a pink and a white flower, a second blue flower of quite a different family might appear and be objected to, and provide a text for a tiny lesson on the need for Latin scientific names, as the simple English ones would not go round even in one well-stocked garden.

Some English names are charming, and should never be dropped when they are reserved for one well-known plant, such as Old Man, Pasque-flower, Rosemary, Honesty, Marigold and Christmas Rose. But others, such as Jacob's Ladder and Bachelor's Button, may be applied to quite different plants in neighbouring counties; and when one gets beyond the old familiar garden favourites of our forefathers and begins to make English names for later introductions, and we find ourselves speaking of the variegated-leaved Fortune's Plantain Lily, or Howell's Brodiaea Lily, it seems better to become sufficiently familiar with the scientific names and call them Funkia Fortunei and Brodiaea Howellii, and so be intelligible to equally well-educated gardeners of all other nations. We may decide that it must be left as a matter of taste whether or no Latin names are uglier than English ones, for it is true that

"Different people have different opinions,
Some like apples and some like *inions*."

* Alcock's "Botanical Names for English Readers" is excellent as far as it goes, but only deals with British plants.

That they are meaningless is true in very few cases to those who will spend a little brain and time in learning to appreciate the knowledge and history stored up in their syllables. The study of words is such a fascinating occupation that, once begun for the purpose of a better understanding of our plants, it will almost certainly add an interest to our lives.

There are few more interesting books to one who likes to know something of the words he uses than a good etymological dictionary, and I find the looking out of one word generally leads one on to scanning a page or two for others. In fact, I agree with a certain old lady who was such a persistent borrower of books that one friend hoped to check her zeal by lending her the first volume of the Oxford New English Dictionary. However, she came back after a week, asking for the next volume, and declaring it was a delightful book, although it changed the subject so often. I feel sure an etymological dictionary of plant names, if fairly complete, would also be a delightful book. At present we have to hunt about a good deal, and the most complete I know of is Nicholson's "Dictionary of Gardening." Unfortunately, the best edition, with the two supplements, is out of print, and becoming scarce. Those fortunate enough to possess a complete copy will find their New Year resolutions easy and delightful to carry out, especially if they study well the list of Greek words used as roots in the composition of plant names, which forms the latter portion of the Pronouncing Dictionary in the first supplement. But the less studious may look up their plants in the main body of the work only. For instance, there is the so-called "Stone-plant." Most of us have had its leaves given us by friends returning from travels in warm climates. They bid us place a stone on the leaf and watch the development of young plants from its notched edges. It must surely add to our interest in it to know that this habit has provided its name of Bryophyllum, from *bryo* (to shoot) and *phyllon* (a leaf). Or who would have guessed, unaided by Nicholson, that the Musk Orchis got its name of *Herminium* from *hermin*, the foot of a bed in Greek, on account of the knob-like shape of the root?

But even this delightful authority is sometimes less informative than could be wished; for though he tells us *Bauhinia* is named in honour of the two brothers, John and Caspar Bauhin, he omits the reason given by Linnaeus, that the two lobed leaves of this genus suggested the propriety of its bearing their name; or, again, that the name *Dorstenia* for a genus with inconspicuous flowers, devoid of all beauty, seemed to the great Swede a suitable allusion to the uncouth and antiquated book of Theodore Dorstenius, a sixteenth century botanist. For such interesting information we must go to the "Critica Botanica," a Latin work by Linnaeus, little studied nowadays, but well worth reading to find such a gem as this: "*Hernandia*, an American plant, the most beautiful of all trees in foliage, but furnished with trifling blossoms, bears the name of a botanist highly favoured by fortune, and allowed an ample salary for the purpose of investigating the natural history of the Western World, but whose labours have not answered the expense." *Diascia* is another disappointment in Nicholson, for it is so dull to believe his statement that it is derived from "*diaskeo*, to adorn, on account of its pretty flowers," when I know I have read somewhere it is from *di* (two) and *askos* (a wine skin), a far more exciting and illuminating idea, for it is one of the

very few plants (*Satyrium*, a genus of Orchids from the Cape, being another) whose flowers have two spurs or honey sacs. Still, as I cannot give you the reference to this more picturesque derivation, you must not regard it as "official." Nicholson also gives a translation of even the most obvious specific names, such as *fragens*, fragrant; *grandiflora*, large-flowered; and *Greigii*, Greig's; as well as more difficult ones like *baccifera*, berry-bearing; *linoides*, Flax-like; *rhombeum*, diamond-leaved; *rhodopterygium*, rose-winged; and *senile*, white-haired. So that a careful study of his pages would go far to make Latin names familiar and interesting to us. The new American "Cyclopedia of Gardening," of which two volumes are now ready, also makes a special point of giving the derivation of generic names, and there is a useful list in the first volume of the specific names most in use and their English equivalents.

E. A. BOWLES.

THE CULTIVATION OF EDIBLE PEAS.

THERE is little doubt that Peas presented at their best form one of the most popular vegetables cultivated in this country, and, except for those who are strictly forbidden by doctor's orders, it is rare indeed to come across anyone who has a real dislike (as is too often the case with other vegetables) to well-grown, well-cooked Peas of the best varieties. There are few vegetables which have been improved during the last half century as this, so much so that it is no uncommon thing to hear of Peas being produced in the open in many parts of the country during six months out of the twelve. Where it is possible to accommodate the earliest sowings under glass, this may easily be prolonged, and at whatever time fresh green Peas are sent to the table, they are bound to be appreciated. This is one of the few vegetables that does not answer readily to the bottling process, and personally I always draw a line at these if I know they have been preserved.

Not from one point of view only, but in every detail has improvement been carefully studied by the raisers of new varieties. Early, midseason and late varieties, dwarf, medium and tall, with constitution, flavour and appearance, have all been carefully brought out, and in every case improved upon. If I were asked from which point of view I considered the least improvement had taken place, I should not hesitate to say in relation to the quality of late varieties. I have always regarded *Ne Plus Ultra*, which I can remember from my youth, as the best flavoured late Pea, but it is in every other way superseded. I made a fairly large sowing of it during the past year side by side with other well-known varieties; but, except for its one good point of flavour, it was easily beaten in every other respect.

Preparation of the Ground.—It is all-important, to obtain the best results, that the ground in which it is intended to grow the crops during the coming season be thoroughly and well prepared during the winter months, and as far as practicable choose a site which has not been occupied by Peas of any kind during the previous year. The ground should be deeply trenched and well enriched with good half-decayed farmyard manure, and

at the same time add, if possible, a good dressing of wood-ashes or burnt garden refuse. For the earliest supplies a sheltered sunny position should be selected, but for midseason and late varieties the more open the position and free from trees the better.

For late sowings an old practice, and a capital one, too, is to prepare trenches much in the same way as one does for Celery; and should the soil be of an unkindly nature for the growth of Peas, it will amply repay to add a quantity of fresh compost consisting of charred loam, leaf-soil, and a moderate amount of bone-meal, the latter being the finest stimulant I am acquainted with for the growth of this crop. At all times allow ample room between the rows, as, the more isolated these are, the better will be the returns; indeed, I favour and practise, as far as possible, allowing sufficient distance so that other crops may be cultivated between them, which is often a distinct advantage to both.

Raising the Seedlings.—During the whole of my career as a cultivator I have made it a practice to raise the earliest and at least two successional sowings in boxes under glass, planting them out in their permanent positions immediately the young plants are ready. For many reasons this plan has a distinct advantage over that of sowing them in the open in the cold, uncongenial soil, which it is bound to be at that season. The germination is much quicker and one has them much better under control as regards the seeds and young growth being infested with the many enemies from which the Pea is likely to be attacked, such as birds, rats, mice and slugs, as well as the outside climatic conditions. If carefully planted, the plants will not suffer in consequence; but, on the other hand, will generally do much better and crop earlier than if sown in the open. One of the commonest mistakes made is that of sowing and planting too thickly. It is unreasonable and against common sense to expect the best returns when such is the case, in addition to being a sheer waste of seed. When sowing in the open, the seed should be placed at regular intervals in a double line just as thick again as it is intended for the plants to mature, to allow for mishaps and failures, and thin out to the desired distance when the plants are about three inches in height. Naturally, the taller and stronger growing varieties will require more room than the shorter ones, and it is practically useless to attempt to grow the very large-podded varieties anything like to perfection when overcrowding is indulged in. At the time of sowing, traps should always be set and examined every morning for the destruction of mice, and

black thread should be stretched along the rows 3 inches from the surface to ward off attacks of birds, which have a particular liking for the young succulent growths of the plants. This will be found to be a most effectual method.

Staking.—Though many inventions have been made for supporting the growths, there is nothing which has come under my notice to equal the old-fashioned plan of using brushy Hazel stakes for the purpose, and, when this is properly performed, certainly nothing is more pleasing in appearance.

PEA DEFIANCE MARROWFAT, A NEW SECOND-EARLY VARIETY OF GREAT PROMISE. (*Much reduced.*)

Mulching.—This will be found most beneficial for early, midseason and late varieties alike, and I prefer long stable litter to anything else. This should be applied just before the plants commence to flower.

Watering.—During spells of drought copious supplies of water should be given at the roots, both clear and liquid manure, properly diluted, and during wet weather occasional applications of some approved vegetable manure will have very beneficial results.

Stopping and Thinning.—When extra large pods are required, it is essential to put this into

practice, and it is astonishing the difference it will make. All side growths should be removed, the points of the leading growths pinched out after a reasonable number of pods have formed, and all small and deformed pods should be removed. In the case of the earliest sowings, it will make many days' difference to the first picking if the points of the growths are stopped when a fair crop is assured.

Varieties.—The greatest care should be exercised in making a selection, and in my opinion far too many varieties are grown by most of us. Endeavour to make sure of those which do best

in the locality, and from four to six varieties should be ample for anyone. Personally, I consider there is no room for the old, round-seeded varieties, and I do not attempt to grow them now, as these are infinitely inferior to the wrinkled Marrowfat varieties, many of which are now practically as early. Gradus or an improved strain of this, such as Early Morn, Early Giant and Edwin Beckett, can hardly be beaten. The latter, as well as being very prolific, producing pods of rare quality, is also the hardiest in this locality. Duke of Albany and Defiance are both especially good varieties for succession. Following these, Quite Content is the largest-podded variety grown, and continues in bearing longer than most sorts. It requires liberal culture, and must be allowed ample room to be a success. As regards the finest exhibition Pea, for late sowings I know of none to surpass or even equal that fine old variety Autocrat, or Masterpiece, which is no doubt a selection from it. It seldom fails in any locality, and it possesses a most robust constitution.

Elstree. EDWIN BECKETT.

A GOOD NEW SECOND-EARLY PEA.

THE accompanying illustration represents a spray of a new second-early Pea that I grew last year for the first time, and with considerable success. This is named Defiance Marrowfat, and was sent out by Messrs. E. Webb and Sons. It attains a height of about four feet and is very robust,

the large, dark green pods being produced mostly in pairs. The pods are well filled and the Peas when cooked are of a rich, deep green colour, while the flavour leaves nothing to be desired. The row from which the shoot illustrated was taken was sown on April 13, and the pods were ready for gathering on July 3. Owing to its comparative dwarfness, I consider this an ideal Pea for small gardens, and have no doubt that it would prove a valuable asset on the exhibition table, its large, beautifully shaped and well-filled pods presenting a very attractive appearance.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Melons.—If ripe fruits are required early in May, no time must be lost in sowing the seed. Sow singly in small pots, and plunge the pots in a hot-bed in a warm, moist house. When germinated, keep the young plants quite close to the roof-glass to encourage sturdy growth.

Late Vines.—There is no advantage in keeping late Grapes hanging on the Vines after this date. The Vines must now be pruned and given a period of rest. If the crops have been unsatisfactory,

a long spell of mild weather. Mice, too, must be watched for, as these are known to cause great disappointment among lovers of rock plants by their destructive habits. After a spell of hard frost it may be necessary to press the soil about the roots of small, choice plants.

The Hardy Fruit Garden.

Planting.—On heavy, retentive ground the work of planting may have been considerably delayed through the continued wet weather during November and December. Lose no time in pushing on with this important work whenever the soil is in suitable condition. To facilitate this work it is a good plan to have a quantity of dry soil ready to hand, as this is more readily worked among the roots than soil which is wet. Standard trees must be securely staked when planted, and the rooting area of all newly planted trees should be covered with short litter. When the ground is frozen hard, the opportunity should be taken to wheel manure to the various places where this will be required for the purpose of mulching.

The Kitchen Garden.

Sowing Peas.—The first sowing of Peas may be made as early in the year as possible. The ground should have been prepared for this purpose in the autumn. It is now generally known that Peas require a deeply cultivated soil and plenty of rich, well-rotted manure to have them in the best possible condition. The early sowing should be made on a warm, sheltered border. Here we sow our earliest batch of Peas in boxes, planting them out at the foot of a wall facing south. Pilot is one of the best early kinds.

Broad Beans.—Make a sowing of an early Longpod kind as soon as the ground is in suitable condition.

Tomatoes.—If not already done, a sowing ought to be made at once. A small, free-setting kind should be chosen for early work. Sow thinly in pans, and keep the resultant seedlings growing quite near to the glass in a minimum temperature of 60°.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Fruit Under Glass.

Vines in the earliest house will now be swelling their buds, and may have a slight increase of temperature; but 58° to 60° at night will be ample. Evaporating pans must be kept constantly filled with water, and a fairly humid atmosphere maintained by giving theinery a slight spraying when the weather is fine. About 11 a.m. is a good time for this to be done, but on dull days a damping of the border and pathway will be sufficient.

Peach Trees in the early Peach-house will be on the point of flowering, and, before the blossoms expand, should be fumigated. This will keep fly in check until the fruit is set. Do not try to hurry progress with this fruit by the use of too much fire-heat at this stage.

The Kitchen Garden.

The Seed Order.—This should soon be put in the hands of the seedsman, so that the various items required this month will be to hand. Delay in sowing may cause disappointment later on.

Rhubarb.—The warm end of a Mushroom-house is an ideal place for forcing this, and it will be found to grow much more freely from now onwards than was the case during December. The roots benefit by being lifted and exposed to the frost before being brought indoors.

Onions.—A sowing of this wholesome vegetable should be made without delay if large specimens are required. Ailsa Craig is one of the best varieties for this sowing. The seed must be sown in good strong loam, to which should be added some wood-ashes, leaf-mould and sand. Place glass over the boxes and put in a house with a temperature of 55° to 60°. The ground where these are to be eventually planted should be trenched deeply, mixing in a liberal dressing of farmyard

manure as the work proceeds. If maggot is troublesome, a sprinkling of some soil fumigant must be applied during the preparation of the ground.

The Flower Garden.

Antirrhinums.—If these are to form part of the bedding scheme, the seed may now be sown in boxes and placed in a warm greenhouse. Antirrhinums are divided into three groups—tall, intermediate, and dwarf. The intermediate section is the most serviceable for bedding purposes, but both the tall and the dwarf are useful, and should be included.

MR. E. HARRISS.

it is a sure sign that something is wrong with the roots. The present is the most suitable time to renovate the borders if they are in need of it.

Plants Under Glass.

Carnations.—Plenty of stimulants must be given to plants in flower. Clay's Fertilizer, or some approved Carnation manure, may be given at every alternate watering. Cuttings inserted last month should now be ready for potting into 2½-inch pots. When potted, place them on a shelf near the glass, and keep them rather close for a few days, after which they must be gradually inured to cooler conditions by the judicious use of the ventilators.

Winter-Flowering Pelargoniums.—The cuttings of these may now be inserted. Choose those shoots which have been exposed to the light, as being most suitable to make strong, healthy plants. Fill a number of 3-inch pots with a light, sandy compost, and insert three or four cuttings round the side of each pot. Water them in and place the pots on a shelf in a greenhouse.

The Flower Garden.

Calceolaria amplexicaulis.—This makes a very effective plant when grown as a standard. For this purpose the plants should now be potted into 3-inch pots, and placed in a moderately warm house. Keep the side growths removed till the plants have reached the desired height. Later on they will require a shift into 6-inch pots.

The Rock Garden.—During mild spells much attention must be devoted to the choicest plants, as slugs are capable of doing much damage even during the dead of winter. Plants which have been protected from severe frost must also be examined. In some cases it may be desirable to partially remove the protecting material during

MR. J. JEFFREY.

The Rock Garden.—Several early flowering plants, including bulbs, will be showing signs of growth, and care must be taken against leaves collecting and so encouraging premature growth. Protect with glass those subjects which it has been found succumb to our winter rains, uncovering when the weather is fine so as not to excite growth.

Plants Under Glass.

House Palms.—Palms that are used for house decoration must be changed periodically. A long spell in the dry atmosphere of a dwelling-house is injurious to them. Where changing is impossible, sponge regularly to keep them healthy and clean.

Schizanthuses.—Plants sown in August and September will now be ready for moving into their final pots. Green fly must be kept in check by occasional fumigation.

Cyclamens.—These will now be at their best, and their flowering may be prolonged for some time to come if helped with some weak liquid manure or clear soot-water.

The Hardy Fruit Garden.

Pruning and Tying.—Advantage must be taken during fine weather to get the work well forward in this department. The wall trees, especially Plums, Cherries and Pears, should be pruned and trained first, so that they may have their winter dressing applied before the buds commence to swell.

Planting.—Where fruit trees are to be planted, the ground should receive a good trenching in advance, digging in a large quantity of manure of a lasting nature.

JOHN JEFFREY.
(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castle Milk Gardens, Lockerbie, N.B.

THE SUPPLY OF SEEDS DURING 1915.

OWING to the war there has been some considerable apprehension as to supplies of seeds during 1915, a good many gardeners anticipating a decided shortage. We have therefore been to some trouble to ascertain whether there is any ground for such fears, and herewith we give the communications received from the leading seed firms in various parts of the country. It will be seen that, although a few kinds may be rather scarce, anything like a general shortage is not anticipated. One effect of the war will, we confidently hope, be to induce seedsmen to grow more seeds in this country than in the past, and so render themselves independent of German and Austrian supplies. The firms' letters that follow are arranged in alphabetical order:

This year we are well supplied with all kinds of seeds, but probably the position in the trade generally will be that there will be a sufficient supply of nearly all kinds of vegetable seeds, but a considerable shortage of many kinds of flower seeds which are grown on the Continent. This will apply especially to Stocks and Asters and similar seeds, which cannot well be grown in Great Britain.—**AGRICULTURAL AND HORTICULTURAL ASSOCIATION, LIMITED, Long Acre, London, W.C.**

So far as we can tell, the war is going to make very little difference, if any, to the supply of seeds in the spring. Fortunately, the season in England was exceedingly good for seed-saving, the weather remaining fine well into the autumn. We, like several other people, fearing a scarcity of many things hitherto drawn from Germany, took the precaution to save seeds from our own annuals and perennials wherever we could, and the result has been that we had exceedingly good crops of Asters and many other annuals. In fact, the crop considerably exceeded our anticipations, and the seed has proved to be of very fine germinating power. With the exception of one or two minor varieties, there will be ample supplies of seed to carry us through the season.—**R. H. BATH, LIMITED, Wisbech.**

As far as we are personally concerned, we have ample supplies of Broad Beans, most varieties of Dwarf French Beans and Runner Beans, although Runners are scarce, and, indeed, some of the varieties of Dwarf French too. Other varieties of garden seeds we are well off for, excepting one or two varieties of the late maincrop Peas. In flower seeds we were extremely fortunate, in that we had planted considerable breadths of Asters, on which we have been working and selecting for some years, and have sufficient English-grown seed of the varieties we offer to fill all demands. We also had, and fortunately so, large breadths of *Antirrhinum nanum* varieties, which, by careful single-plant selection, we have managed to get now to breed true to colour and type, and have no doubt these will take the places largely in many gardens of Asters and Stocks, in that they do not suffer from any disease and are so free flowering that quantities of bloom may be cut from them without defacing the bed. A few varieties of Sweet Peas are scarce, especially scarlets and salmon orange varieties such as *Barbara* and *Inspector*.—**ALEX. DICKSON AND SONS, LIMITED, "Haulmark," Belfast.**

It is difficult to say definitely at the present time what seeds will be available for spring, but with regard to vegetable seeds, supplies are now coming to hand from growers, and are of a satisfactory character. We think the stocks available will be quite sufficient to meet all requirements so far as we are at present able to say. With regard to flower seeds, some of the choice varieties of Asters, Stocks, Balsams, Petunias, &c., for the supply of which we have hitherto been largely dependent upon Germany, must this year show a considerable shortage, but the harvest of most of the hardy and half-hardy annuals has been abundant, and will be quite equal to meet the demand.—**DICKSONS, Chester.**

So far as we are concerned, we hope to be able to offer our customers vegetable and flower seeds much as usual. We have made a point of buying home-grown seeds wherever possible, and have almost filled up our requirements.—**DICKSON, BROWN AND TAIT, Manchester.**

We are having no trouble whatever in getting our supplies of flower and vegetable seeds. Of course, it must be kept in mind that we grow a great many things at our seed farm at Mark's Tey, Essex, with the result that we do not require to buy largely. Furthermore, our supplies are coming to hand in good time, and we hope by the time this appears to be in a position to fill all orders.—**DOBIE AND CO., Edinburgh.**

I do not think the general public need fear a shortage of seed for 1915, at least. Crops generally here proved

a fair average, and we have in several instances been able to reduce prices.—**HENRY ECKFORD, Wem.**

NATIVES of these islands need have no fear of any shortage of garden seeds in the spring, that is, any general difficulty in obtaining supplies. No doubt some sorts will be scarce from ordinary natural causes unconnected with the war. For instance, Onion and Carrot seeds were known to be a very poor crop before war was declared. One or two kinds of Peas, such as *Pilot*, failed nearly everywhere. The commoner kinds of Runner Beans, which come from Austria, will not be available unless unpatriotic people import them indirectly; but, excepting such wholesale houses as usually depend largely upon Germany, the trade will get their supplies. Foreign deliveries from other parts of the Continent will be late, and prices will necessarily be somewhat advanced because of extra expenses in overcoming difficulties of transport, and also on account of the financial situation. But England is not, as so many imagine, dependent on Germany for seeds. The Germans have cleverly put this view forward for acceptance, but as a matter of fact British wholesale houses sell large quantities of seeds to Germany and Austria. As wholesale seed-growers my firm would not worry if Germany ceased supplying seeds to-morrow. As seed merchants we should, of course, be extremely pleased. Before closing this note, may I express the hope that your readers will sow even more seeds than usual. It will in these times, when people are practising all kinds of strange so-called "economies," be a boon to hundreds of seedsmen scattered throughout the kingdom who have only the profits of the spring season to look to for their means of livelihood.—**JAMES KELWAY, Langport.**

ON the outbreak of the war no doubt many seedsmen were wondering how it would affect the seed supply, and much anxiety was felt as to whether many of the so-called German flower seeds would be obtainable at all. I am glad to say that the seed trade has not suffered nearly so much as might have been expected. In the case of vegetable seeds there seems no great shortage, with a few exceptions, such as Runner Beans and Carrot, which are both very scarce and dear. Both of these seeds are very largely grown in Germany. I remember, when going round Messrs. Dippe Brothers' place in Quedlinburg many years ago, seeing a huge field of Carrot seed and remarking, "Where on earth does it all go to?" "Well," said my guide, "we send some seven to ten tons every year to one wholesale firm in London." When parcels of that size are not coming into the country, it must make some difference. In the case of flower seeds, the home growers have been able to supply nearly everything usually looked upon as German produce. My own firm catalogues some 400 varieties of flower seeds, and out of this long list I do not think there were six which could not be obtained from home growers. This is very satisfactory, both for the retail seedsmen and the consumer. It is also satisfactory from a national point of view, for if our English growers can supply seeds equal to those imported, a great many thousands of pounds may be kept in the country which has in the past gone abroad. There is generally some good comes out of evil, and good will certainly come to the seed-growers of this country if they will make the necessary effort to meet the extra demand for seeds, orders for which have in the past gone abroad. I think seedsmen may look forward to the coming season hopefully, for seeds, especially vegetable seeds, are a necessity, not a luxury; and in the present time of stress it behoves every garden-holder to cultivate his plot to the utmost, so as to increase the food supply of the nation. Even in the case of flower seeds, they are so very cheap that no doubt many will be sown to take the place of the more expensive bedding plants.—**J. DUNCAN PEARSON, Loddham, Notts.**

WE have not the slightest difficulty in procuring supplies of all we require, and we have already made arrangements for everything. Our seed catalogue is now in the printer's hands, and contains everything that we have hitherto offered, together with some additional novelties. Except in one or two trifling instances, our prices have not been raised in any degree, and the general range will be found to be extremely reasonable. We have not been dependent upon Germany for several years, and many more seeds are now being produced at home than was the case a few years ago. The beautiful summer and perfect harvest weather of the past year have ripened English seeds in such a manner that they can compare favourably with any Continental productions.—**PENNELL AND SONS, Lincoln.**

IT is quite possible that the total amount of seed in this country at the present time is below the average, partly due to the short yield of many English-grown crops, which were affected by the drought, and partly due to the fact that many Continental supplies are cut off. We are very pleased, however, to say that owing to our system of seed production in various parts of the world and our methods of calculating and providing for our requirements, we hold abundance of seed of almost everything for the coming season, and we have every reason to believe that we can meet the ever-increasing demands made upon us.—**SUTTON AND SONS, Reading.**

ALTHOUGH there is a shortage in many crops, we have been able to secure what we think will be sufficient for our seed trade during the coming season; but, nevertheless, there are many varieties that will be short, and we fear when the original stock is sold there will be no

means of replacing them. There seems to be no scarcity of Broad Beans, but Kidney Beans, particularly the dwarf varieties, seem to be rather short, and prices are considerably higher than they were last year. Of culinary Peas there seems to be a fairly good supply of most varieties, although here and there prices are rather higher than last year; yet, on the other hand, a few varieties are a little less in price, but take them all round there will be plenty of Peas for the coming season. There is plenty of such things as Beet and most varieties of Brassicas; but Carrots are very scarce, and consequently prices have had to be a little advanced. Onions are also scarce, and prices much higher than last year; but such things as Lettuce, Radish, Spinach, Turnips, &c., are much about the same as last year. There seem to have been fairly good crops of Potatoes, and these prices will be about the same as last year. Of course, there is not much difference in the supply of flower seeds, apart from Asters and Stocks, many of which are usually imported from Germany; but we believe there are strains grown in this country equally as good, so that we shall get on very well without the supply from Germany.—**ROBERT SYDENHAM, LIMITED, Birmingham.**

THERE need be but little doubt that we shall have enough of practically every kind of flower and vegetable seed that is required. Sweet Pea seed is fairly plentiful, and there will be over and above what is required. Of vegetable seeds we shall have plenty, with the exception of one or two lines. Of culinary Peas there is an abundant crop in England, and of most other vegetable seeds we shall have sufficient. No doubt there will be a shortage of some flowers; but, on the other hand, of all the leading sorts we shall have enough, as there has been an unusually heavy crop of flower seeds throughout the country, and no doubt, owing to the war, most growers harvested as much as possible. I think I am right in saying English growers have placed too much reliance on some seeds grown by foreigners, and there is no doubt that we can grow a quantity of seed in this country quite equal to the Germans. As far as the English grower is concerned, in a good many items I believe this war will be a blessing in disguise, as our growers will now put their shoulder to the wheel and grow as much as possible at home, which must be better for our country, and certainly no worse for the English amateur. No doubt there are several flower seeds that cannot be grown successfully in the British Isles, but these our Colonies can supply. Colonists are taking advantage of this war, and are catering very strongly for our trade, which is desirable.—**W. J. UNWIN, Histon, Cambs.**

OWING to our unique facilities we do not anticipate any difficulty in being able to supply customers with their usual requirements of vegetable and flower seeds, Potatoes, &c., during the coming season, with the exception of French and Runner Beans, which have proved a light crop owing to frost and unsuitable weather for harvesting and a shortage of Continental supplies, thereby causing a slight advance in the prices of these articles. There are good general supplies of home-grown seeds of first-rate quality available at about normal prices, and our stocks are sufficient to meet the usual demands.—**E. WEBB AND SONS, LIMITED, Wordsley, Stourbridge.**

WE do not anticipate any serious shortage of seeds owing to the war. With the exception of one variety of Bean, we have so far met with no inconvenience with any of our contracts. Some flower seeds will possibly be scarce; but, generally speaking, horticulturists can rely upon receiving seeds of equal quality to those of an average year. The war will, no doubt, foster the business of seed cultivation in this country, some of which has hitherto been done in Germany and Austria, and in this respect we venture to say an improvement in the strains may be confidently looked for.—**J. C. WHEELER AND SON, Gloucester.**

NOTES ON VEGETABLES.

IFIND from conversations with readers that there is a desire for information for a selection of varieties. With so many excellent sorts noted in catalogues, it is difficult for the inexperienced to pick out the most deserving, and, what is important to such cultivators, they need some data when to sow or plant, the distance apart, position in the garden, and when such crops may reasonably be expected to be ready for use. My first notes in *THE GARDEN* for 1915 shall be devoted to this subject, commencing with Potatoes, which are the leading vegetable for all types of cultivators.

Potatoes.—First early: May Queen, sprout in boxes, plant on a warm south border in rows 2 feet wide, tubers 15 inches apart, the middle of March. If protected from frost, should be ready to dig the first week in June. Second early: Carisbrooke Castle is a most desirable

Potato. Its cooking qualities are of the highest standard of merit, which not only prevail at digging-time, but are equally so throughout the winter following. As an exhibition variety this Potato should have a bright future. Planted in the open in rows a yard apart early in April, the tubers should be ready at the end of July. Up-to-Date is still the best maincrop Potato, succeeding in any class of soil.

Peas.—The Pilot is an excellent early cropping variety. Sown early in March on a warm, sheltered border, pods should be ready to gather early in June. Duke of Albany is still the best maincrop variety. Sown thinly in rows in an open site early in April, the Peas should be ready for use at the end of July. Quite Content is also desirable. Sown about the middle of April, they will be ready for use the first week in August. As a late Pea The Gladstone is an excellent variety. Sown the end of May or early in June, good pods should be gathered in September. Later sowings will give desirable crops in October.

Broad Beans.—Still the best early sort is Broad Windsor. Sown in February on a warm border, they should be ready for use in June. Leviathan, as its name implies, grows larger in the pod than the former; will be available in July.

Runner Beans are best represented by Prize-winner or Ar. Sow in pots or boxes early in May. Plant out when 6 inches high in single rows. They should be ready for use the second week in August.

French Beans are still best represented by Canadian Wonder. Sow on a warm border the middle of May. Gather in July.

Onions in variety are numerous. Globe Tripoli sown early in August gives useful bulbs in June and July. James' Long Keeping, if sown in the open in drills 14 inches apart, will provide a good winter supply of serviceable bulbs. For exhibition, Ailsa Craig is the best Onion in commerce. Seed sown in boxes under glass in January, carefully grown on and planted in well-prepared soil, will produce handsome bulbs in August.

Parsnips.—One variety only is required. Tender and True is perhaps the most useful, growing easily into roots of good shape and quality. Seed sown in the open in February will give handsome roots in September.

Beet is a useful and easily grown vegetable or salad. For an early supply Globe is good. Sow in April on a warm border; ready end of July. Blood Red as a maincrop variety, sown the first week in May, will produce desirable roots in August.

Celery is an important vegetable, having a long season; in use from August until April. Sow the first pinch of seed under glass in gentle heat in February, and successively to the end of March. Solid White and Aldenham Pink are desirable varieties.

Carrots are in use practically all the year round. Sow Early Forcing and Early Gem in frames in January. For an outside crop sow Early Nantes on a warm border in March, New Intermediate for the main crop in the open early in April, in drills 15 inches apart in deeply dug soil.

Broccoli is an important crop, as so much depends upon the manner in which the plants survive a hard winter. For a supply of heads during November and the following six months commence

with Michaelmas White, following with Autumn Protecting, Christmas White, Leamington and Model for a late supply. From the first week to the middle of April is a good time to sow the seed, at first in a cold frame, afterwards in the open. Any open site with plenty of space between the plants will grow good Broccoli.

Brussels Sprouts are one of the most useful vegetables in the garden. Coming into use in October and lasting until April, it is surprising what a quantity one well-grown plant will produce. Too often the plants are not given time to grow and develop. The first pinch of seed should be sown in the middle of March in a cold frame, the second batch in the open in the first week in April. Exhibition and Dwarf Gem are the two best varieties.

Cabbage.—Ellam's Early is still one of the best early varieties, followed by April, Favourite and Imperial. Sow seed at the end of July and in the middle of August; plant out in batches in rows 2 feet apart, plants 1 foot, with a view to cutting out alternate plants, thus economising space.

Savoys are useful in the autumn, giving a huge crop from a small space. Perfection and Early Ulm are good sorts. Sow in the open in April and treat as Cabbages.

Leeks are now much more in demand than formerly. Prizetaker will supply all that is necessary. Sow seed in January in gentle heat, and pot on as required. Gradually harden off and plant out the same as Celery in trenches in single rows; plants 15 inches apart. In use from September onwards. Sow seed in the open in March; plant in rows 2 feet apart, making holes 15 inches deep.

Turnips are an indispensable crop. Early White and Red Milan are the earliest. Sow seed in a slight hotbed in February, to be followed in the open in March. Snowball succeeds by sowing repeatedly in small patches from April onwards to the end of August. Prizetaker and Orange Jelly are desirable for a winter supply, sowing the seed in August.

Vegetable Marrows bear abundantly with a minimum of trouble. Moore's Cream sown under glass in March will give an early crop if carefully protected when put out, to be followed by Long White and Long Green. Sown in the open, or, better still, in a cold frame in April, these will give a supply until frost.

Cauliflowers are in use from May until succeeded by the Broccoli in October. First Crop sown in January and February in gentle heat, grown on in pots, will give early heads; followed by Magnum Bonum sown in March in a cold frame and again in the open in April; then by Autumn Giant sown in September, kept in pots and put out early, again sowing in the open in March for a late supply. Abundant space should be given to Cauliflowers to admit of the leaves having free and full development. Varieties like Autumn Giant should have the rows at least a yard apart.

In the case of Peas and Runner Beans, the rows should run, if possible, from north to south. In this position the plants obtain a more equal share of sun than if the rows run from east to west. It is a mistake to overcrowd the rows or the plants in the rows. It is far better to arrange the rows 8 feet or 10 feet apart and grow other crops, as Potatoes, in between.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice. The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

REPLANTING YUCCA GLORIOSA (Yucca).—The best time for replanting would be either September-October or March-April, and as the former is past, you had better now wait till March, choosing a moist or damp time. You might well risk the planting of a 3-feet-high specimen, the measurement being taken from the ground-level to the tips of the heart leaves. Examples of that size usually transplant quite well. Points of cultural importance include a deeply dug soil, the addition of a little thoroughly decomposed manure, and good drainage. Where the staple soil is heavy, it should be lightened, warmed and drained by adding grit, old ceiling plaster or finely broken sandstone liberally, and with these firm planting should be indulged in. We sympathise with you in the loss of the old plant, though, if only "blown down" and not decayed, it should be possible to raise it again, fixing it in position for the time being by means of cross-stakes fastened to the trunk. Even if decayed, the branches torn off from the main stem, with a "heel" attached, and planted against a wall in sandy soil would in course of time form roots afresh and afford a link with a time-honoured specimen.

THE GREENHOUSE.

PROPAGATION OF NEW CHRYSANTHEMUMS (M. E. G.).—The old plants of varieties that are shy in the production of cuttings should be top-dressed with a thin layer of loam, sand and leaf-soil in equal proportions. The plants must be placed in a temperature of about 60° and the surface soil kept in a moist state, but not saturated. If stem cuttings are required, as in the case of the fixing of sports, the stems to their whole length should be laid in a sandy compost on a stage, and, to enable this to be done, the pot must be placed firmly and in a slanting position. Lightly cover the joints with the soil and lay pieces of brick or stone on the stems between them. Keep the compost moist.

HUMEA ELEGANS AND SKIN IRRITATION (d. J.).—It is now a well-recognised fact that Humea elegans is dangerous to some people, as, if handled, it causes a form of skin irritation which takes some time to allay. In our own case we several times suffered from inflammation of the eyes, which used to take several days of medical treatment to cure. After various suggestions as to the cause, the fact was at last noticed that it always came on after handling the Humea. This was taken as a warning, and never since then have we been troubled. Two years ago, however, when in the gardens at Hampton Court, we stopped to admire a fine bed of this Humea, standing on the leeward side while a brisk wind was blowing. In a few moments the one-time familiar smarting of the eyes set in, so that we at once moved and the worry passed off. It is therefore evident that this Humea is, like Primula obconica, a plant which can be dangerous to some people. Personally, we have not suffered in the hands or arms from touching either of them, but the eyes were a different matter.

THE GARDEN.

No. 2251.—VOL. LXXIX.

JANUARY 9, 1915.

NOTES OF THE WEEK.

Apples Wanted for Wounded Soldiers.—The Hon. G. Eden, 6, Cromwell Place, London, S.W., writes as follows: "If any of your readers have got more Apples than they can use, either eating or cooking, they would be very much appreciated by the wounded soldiers in the Victoria Hospital. Any gifts addressed to the Matron, Victoria Hospital, Tite Street, Chelsea, or to me here will be gratefully acknowledged." We hope those of our readers who can spare fruit will send it to either of the addresses given; our soldiers deserv[e] all the good things we can possibly provide them with.

Votes for the Gardeners' Royal Benevolent Institution.—We shall be glad if any of our readers who have votes to spare for the election of candidates to be held on Thursday, January 21, will kindly send their signed voting papers to us. We are interested in a thoroughly deserving case, and all votes received will be devoted to the candidate.

"The Sweet Pea Annual for 1915."—This, the official organ of the National Sweet Pea Society, is one of the most interesting numbers ever published by the society, and should be read by all who are interested in Sweet Peas. Among those who contribute articles are such well-known experts as the Rev. J. Jacob, Messrs. Thomas Stevenson, William Cuthbertson, J.P., V.M.H., W. Lumley Perrier, T. A. Weston, S. M. Crow, G. F. Drayson, Frank Cuthbertson, T. H. Dipnall, E. R. Janes, J. Harrison Dick, and Hamilton Charnock Mott of New South Wales. In addition there is a full report on the work of the floral committee, an audit of the London show, list of too-much-alike varieties, an up-to-date selection of varieties arranged by the floral committee, and a report on the so-called "streak" cures sent in by vendors for the society to test. The Annual is well bound and illustrated, and should be on the shelf of every Sweet Pea lover. Copies have been sent to members of the society, but non-members can obtain them from the secretary, Mr. H. D. Tigwell, Greenford, Middlesex, post free 2s. each.

Buddleia officinalis as a Small Pot Plant.—In House No. 4 at Kew just now may be seen some interesting plants of this Chinese shrub.

These are growing in 5-inch pots, and each is carrying several racemes of flowers. These are pale lavender in colour, with a conspicuous orange eye, and emit a strong fragrance similar to that of honey-comb. The plants under notice have been grown from cuttings rooted early in the spring, each having its point taken out when growth was active, so as to induce a bushy habit. Although not particularly showy, they provide a welcome and interesting change from the Pelargoniums, Begonias and Carnations that too often monopolise conservatories in private gardens at this season.

The Nomenclature of Sedums.—Considerable confusion appears to exist in gardens over the

A Beautiful Flowering Privet.—*Ligustrum lucidum* is one of the most valuable species of the genus. With us it is a large evergreen shrub or small tree, but Mr. E. H. Wilson, during his travels in China, met with it forming fairly large trees as much as 40 feet to 50 feet or even more in height. As a large, shapely, evergreen bush with rich glossy green leaves, it is the most handsome shrub of the genus for a lawn specimen. Coupled with this, during September it flowers freely, most of the shoots terminating in erect panicles of white flowers 6 inches or more in length. A good-natured shrub, thriving in most soils and situations, it is surprising we do not meet with bushes more frequently in gardens. The year 1794 is given as the date of its first introduction to British gardens from China.

■ A Charming Greenhouse Plant.

Saintpaulia ionantha, illustrated on this page, is one of the most useful and easily grown greenhouse plants that we know. It may be readily raised from seed sown in February or March in pans of well-drained sandy soil, the seedlings being subsequently pricked off and potted up singly when large enough. Good loam, with some decayed leaf-soil and sharp sand, forms a suitable mixture for the plants to grow in. Seedlings raised in early spring often commence to flower in August, and, if given a warm greenhouse temperature, will continue well into the winter. The blossoms are deep violet in colour, though they vary in their intensity on different plants. There is a variety with so-called white flowers, but the deep blue is much the best. Leaves placed on well-

SAINTPAULIA IONANTHA, A CHARMING DWARF GREENHOUSE PLANT WITH DEEP VIOLET FLOWERS.

names of cultivated Sedums, one name being attached to quite different plants, while identical plants are often grown under different names. In order to be able, with the help of experts in the genus, to straighten out this muddle, the Royal Horticultural Society is endeavouring to get together at Wisley a complete collection of Sedums, and will be very grateful for plants or cuttings to grow on for comparison from as many sources as possible. Specimens should bear the name under which they are known, and should be sent by the end of February addressed to The Director, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey.

drained pots of sandy soil and kept in a close, moist atmosphere will easily root and produce an abundance of young plants; hence there is no difficulty in obtaining a good stock once a single plant is available. It was first introduced to this country from Eastern Tropical Africa in 1893, and deserves to be much more widely known. As will be seen in the illustration, its habit is quite dwarf, and for that reason it makes an excellent subject for placing as an edging to the front of the stage, or for a shelf at the back near the glass, where its violet flowers are seen to the best advantage.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Chrysogonum virginianum Flowering on Christmas Day.—I see I have made a note to the effect that this plant was carrying several flowers on December 25. True, they were somewhat marred by the heavy rains; but how brave and persistent was the plant to keep flowering so late! Another of its commendable features is its willingness to thrive in shade or sun, the chief difference between the two places being that in the sun growth is more restricted and the flowers more freely produced. We grow it in the rockery, but it will do very well for front positions in flower borders.—C. TURNER, *Highgate*.

Poplar Trees as a Commercial Asset.—Hitherto probably one of the least valuable of timbers, there appears to be at present a demand for Poplar in quantity, this being directly due to the effect of the war. It is used largely in the manufacture of matchboxes by a veneering process, one firm alone in this country using nearly a million and a quarter cube feet annually. Practically the whole of this comes from Continental sources, which are closed at present. It is used immediately after being cut, so that if anyone is contemplating the removal of Poplar with a view to replanting with better trees, now is the time, as with the cessation of the war the Russian and other supplies will be coming in again. The Aspen Poplar is the best for the purpose.—G. D.

Iris tingitana in Flower at Christmas.—Those who were at one of the Royal Horticultural Society's meetings at Vincent Square just before Christmas of 1913 may remember some fine flowering plants of the above Iris shown by Messrs. Barr and Sons. I had some bulbs from them in September last, which were at once potted and placed in a cold frame till about six weeks ago, when they were brought inside, into a temperature of 50°, which was gradually increased to 60°. They are now (at Christmas) making a brave show, flowering just at the time they were required, and I see great possibilities in them as a winter cut flower, as they have plenty of substance and are far more lasting than *I. stylosa* (unguicularis), now flowering, and, in addition, they have the fine length of stem required for cutting and market uses. I understand from Mr. Rudolph Barr that the bulbs, after being collected, are grown in the South of France, where they thrive and ripen well, and show no signs of disease. Given a regular and well-maintained supply, it is reasonable to prophesy a future for them.—F. H. C.

A New Poinsettia.—The bestowal of an award of merit on a new Poinsettia, which was done on December 15 last, is the first to which that honour has been given. True, two first-class certificates have been gained, but that was in the days when these honours were more freely given than they are now. The last time was in March, 1877, when a first-class certificate was bestowed upon Poinsettia pulcherrima plenissima, a form on which great hopes were centred, but were never realised. In this the flower bracts are far more numerous than in the ordinary kind. The new-comer which has just received an award of merit is P. pulcherrima rosea, the blossoms of which are of a rose pink colour. As this Poinsettia is apparently of good habit, while the bracts are of large size and freely borne, it will, no doubt, soon become popular.—H. P.

The Journal of the Royal Horticultural Society.—The Fellows of the Royal Horticultural Society are proud to know that its reputation extends beyond the British islands, and are desirous of both giving and receiving information on foreign horticulture. No doubt some copies of the Society's Journal find their way to the United States, but it would be interesting to know whether they are sufficient in number to justify the large amount of purely American matter which for a long time has been regularly incorporated in the issue and is quite valueless to the ordinary home reader. The last half volume—of November, 1914—contains, apart from the record of the society's proceedings, 163 pages of contributed matter. Sixty of these are "Notes and Abstracts," comprising 256 paragraphs, no fewer than 151 of which are absolutely, and for the most part abstrusely, American. Personally, I am greedy of general knowledge, but find neither instruction nor amusement in "The Rough Bark Disease of Yellow Newtown," "Blueberry Culture," "The Fern Caterpillar of Florida Greenhouses," "Lady Beetles of Connecticut," "Manganese on Pine-apple Plants," or "Red Spider on Hops in the Sacramento Valley," and I am weary of the perennial Colorado Potato beetle. If the Journal circulates largely on the American continent and such items are eagerly absorbed—though it would seem rather superfluous to reprint and export what has already been published over there—let us not raise any selfish objection. But if not, is it uncharitable to call this very dull padding?—G. H. ENGLEHEART, *Dinton, Salisbury*.

The Banksian Rose.—Some of your readers have experienced a difficulty in getting this Rose to flower. One hopes, however, that their remarks will not discourage people from growing it, because it is really a good Rose. It is one of the most free flowering of all the pillar Roses; the bunches and sprays of buff yellow blooms covering the wall of a house right up to the eaves is a glorious sight. That it is in itself very free flowering, everyone will tell you who has seen it in the South of France. It is also the most rampant of the summer-flowering Roses, and retains its mildew-proof foliage right through the winter and until the new spring growth appears; and for this reason it is the best of all Roses for covering bare walls, especially the southern front of a house, no matter how high. It will run up 12 feet or 15 feet in one year, and eventually right up to the eaves, round the windows and even over the roof. The Virginian Creeper is not in it, compared with the double yellow Banksia. It never seems to grow old; twenty, thirty years hence will find it as vigorous as when it was first planted. If some cannot make it flower, the cause will probably be found in climate and treatment. As to climate. It is quite hardy, and is never injured by winter frost. But it comes into flower in May, sometimes in April. One month before it flowers, the clusters of buds are formed. This is an anxious time for fruit-growers, and the weather that destroys the Peach blossom will destroy the swelling buds of the Banksia unless they are protected. The overhanging eaves of the house will generally afford the buds sufficient protection. With reference to the next point, treatment. All soils suit it, but a warm, gravelly soil, no matter how hungry and dry, is the best. No; it is not in the soil wherein lies the difficulty, but in the pruning. Unlike the multiflora, the strong rods made the first year will not bloom from the laterals the

second year. The blooms are borne on the laterals of the laterals, and in the third year. In other words, the strong rods take three years before they bear flowers. Therefore, if we treat the Banksia as we do Crimson Rambler or Blush Rambler, for example, we shall be cutting out all the next year's flowering wood. If you have space, prune it but seldom, but if it grows beyond bounds, remove most of the strong, long-jointed rods (leaving a few for future blooming) and keep as much of the short twiggy growth as you can, for that alone the next summer will bear flowers. The writer has grown all four varieties of the Banksia, and values them especially because they flower so early. He has exhibited bunches of the single yellow at the May show of the Royal Horticultural Society in the Temple Gardens.—JOSEPH H. PEMBERTON.

A Hedge of Sorts.—I am planting a hedge. "Nothing to make a fuss about," you will say. Ah! but this is not to be an ordinary Quick-set hedge, neatly clipped, but a hedge long dreamed of; a hedge made (like little girls) of "all that's nice." I have had gardens and hedges many and various in my life, but all inherited ones. But now I am going to make a garden that is "all my werry own"—three acres (no! no cow, thank you; she has materialised as a goat) taken out of a meadow on a south-west slope. In the legal document conveying the same (among many other liabilities), Anne Amateur, spinster, doth covenant to "plant a hedge of sorts." Oh! musty-fusty Lawyer, I thank thee for that phrase! Little did the land-shark who penned it dream what a vision of delight those last little words conjure up. My landlord—prosaic mortal!—has put up a line of Larch posts, and oh! horror! barbed wire to keep his cattle from trespassing on my garden that is to be. So, by way of a start, as this is in the county where "Ghostesses sit on postesses, drinking of toastesses," I have begun by planting a Penzance Sweet Briar by each post—so that we may have "roses to make posies for our noses." Between the Sweet Briars are Japanese Rose bushes (also "of sorts"). Later on I thought of adding Sloes and divers Thorns, Japanese Plums (a very few) and Palm to cheer us when spring's delights are reviving; Almond trees, too, with Bullace and Damsons, followed by Wild Cherries and Crab Apples. Will someone who may read this kindly tell me which kind of Crab has the most beautiful blossom and which the most brilliant fruit? By way of autumn colour I purpose planting some American Maples, and should be grateful for information concerning these also. The first I ever saw were in Ruskin's garden beside Lake Coniston, many a long year ago. Then, too, for winter colour there will be brown Beech leaves and some green and golden Gorse and "heavy-greens," as one of my maids was wont to term them; Holly and Laurel—which last, though belittled by Mr. R*b*n*s*n, was praised by Tennyson, "The twinkling laurel scattered silver lights." Twining among the hedge here and there will be Honeysuckle and Clematis (also "of sorts"), and the wild black and white Bryonies, with their beautiful foliage and berries. The wild Wayfaring Tree, with creamy discs of blossom and ruby clear berries, and Kentish Cobs and the purple-leaved kind will have a place, too. And now, as "in the multitude of counsellors there is wisdom," will anyone send me further suggestions for my "hedge of sorts"? They will be gratefully received by—ANNE AMATEUR.

The Daffodil Season.—It seems to me that we are at last back again to a normal season. In 1913 I had flower-spathes ready to burst at Christmas, but last year, although there were a good number of noses showing, the majority were well underground.—C. LEMESLE ADAMS.

Transplanting Christmas Roses.—I notice on page 618, issue December 26, an editorial query against Mr. Bunyard's advice to plant or transplant these in spring, but I have good reason to agree with the writer. I never succeeded well with Christmas Roses until I happened, some years ago, to see such wealth of them in Sir Ralph Anstruther's garden at Balcaskie in Fife as I had never beheld anywhere else. Mr. Maule, the head-gardener, told me the secret of his success, which was to trench the ground thoroughly, laying some well-decayed manure at the bottom of the trench, cover it with sound loam, and set the plants out in March. I followed his instructions, and have never met with the slightest difficulty or disappointment since. Sir Ralph was so kind as to give me a dozen clumps of *Helleborus niger maximus* at that time, and these, now in their sixth year, have been one mass of blossom since the early days of November.—HERBERT MAXWELL, *Monreith*.

— On page 618 the Editor very wisely and rightly queries a sentence in the note by Mr. G. N. Bunyard concerning these plants, which runs: "When it is necessary to transplant them, the best time for doing the work is in spring." In support of the editorial query, let me say at once that it would be difficult to select a worse time than that recommended, and I have not the least hesitation in saying that transplanting done at that time has been among the chief factors in depleting our gardens of one of the most precious of winter flowers. In "The Hardy Flower Book," page 96, I have distinctly laid it down that "essential cultural details are deep sandy loam—3 feet of it where possible—perfect drainage, light shade and, *greatest essential of all*, September or October transplanting." This sentence was written and italicised advisedly by reason of its importance, in the hope that a life-long study and experience of hardy plants—during which Christmas Roses received particular attention—may have some weight with gardeners and others interested in plants which are generally supposed to be impatient of disturbance. That those in question are not so may be gathered from the fact that one of the best amateur cultivators of the flower I have known consistently for years divided and replanted much of his stock biennially, the handsome flowers—the product of this cultivation—the best answer to those who consider the Christmas Rose "impatient of disturbance." They are all this latter, however, and resent it in proportionate degree if disturbed at a wrong time, and there are few worse seasons than the much too elastic one of "spring." For twenty years or more I have preached the value of early autumn planting for these things, the need for which was revealed to me after much observation, from some pot-grown examples in the main. The reason is not far to seek. Christmas Roses are periodical in their rooting, producing their root fibres in two sets like a Daffodil, the main or basal set issuing from the rhizome in the early

autumn, the second or lateral set of root fibres appearing on the first-named set in spring contemporaneously with the new leafage. This is the natural order of things for plants under normal conditions. By planting in early autumn, the main set of root fibres issued annually are secured intact, and all else follows in good order. Disturbed at other seasons, these main roots—virtually the backbone of the plant—are ruined; since, once mutilated, they *never elongate*—frequently they perish outright—with the result that the plant is thrown upon its own resources for months. The debilitated condition which follows is what the gardener calls "impatient of removal." A better word would be "resentment." The truth of the above has been vividly brought home to me during the past few months. At the end of March last, owing to a change of address, I

LILIUM BROWNII, ONE OF THE MOST BEAUTIFUL OF ALL HARDY LILIES.

was compelled to lift my plants at a moment I realised to be highly detrimental to their welfare. To-day they are flowerless and as miserable-looking as I am miserable concerning them. Moreover, they will be greatly weakened, because they were unable to make their proper growth last spring and summer, and will take time to recover. What can be done for them will be done till next August is out, when I hope to be able to give them "another chance" by dividing and replanting them at the right moment.—E. H. JENKINS.

FORTHCOMING EVENTS.

January 19.—Royal Horticultural Society's Fortnightly Exhibition and Meeting, Vincent Square, Westminster, 1 p.m. to 4.30 p.m.

January 21st.—Annual Election of Candidates for the Gardener's Royal Benevolent Institution, Simpson's Restaurant, Strand, London, W.C., 2.45 p.m.

SOME HARDY LILIES.—II.

(Continued from page 4.)

THE genus *Lilium* has been classified in five groups or sub-genera as follows:

1. *Eulirion*, with trumpet-shaped flowers, borne horizontally, of which the Madonna Lily (*L. candidum*) may be taken as the type.

2. *Archelirion*, with flowers set horizontally and opening widely, as in *L. auratum*.

3. *Isolirion*, with upright vase-shaped flowers, as in the common Orange Lily (*L. croceum*).

4. *Martagon*, in which the perianth is recurved, forming the type of blossom popularly known as Turk's-cap.

5. *Cardiocrinum*, a small group consisting of three species only, distinguished from all other Lilies by their great stature and broad, stalked root leaves.

In a sixth group, *Notholirion*, have been classed certain Lilyworts intermediate in character between *Lilium* and *Fritillaria*; but with these I do not propose to meddle at present.

SUB-GENUS EULIRION.

***Lilium Brownii*.**—There has been much confusion among the Lilies classed as varieties under this homely title. For more than a century Brown's Lily has been grown in Europe; but you shall look for it in vain, except as a pot plant, in ninety-nine gardens out of a hundred. Yet, given considerate treatment, it is one of the crowning glories of the border in July. Plant it deep in gritty loam, without peat and with lime and wood-ashes, if possible on a sharp slope, and it will withstand the worst our wet winters can do to it, increasing steadily by bulb offsets and unfolding its great blossoms with unfailing freedom, borne on stout stems 3 feet high. The flowers are funnelled and gracefully reflexed, the outer segments rich maroon on the outside, the inner ones with a narrow stripe of the same colour down the centre, both being purest ivory white inside, with brown anthers. Where a situation on a steepish bank cannot be found for this Lily, the bulbs may be set on inverted pots to secure rapid drainage, or, as the late Dr. Wallace recommended, the bulbs may be planted on their sides, as Japanese gardeners do, to prevent rain-water lodging between the cupped scales.

***L. Brownii odorum* (syn. *colchesterense*).**—It is not easy to understand the system under which this Lily is classed in the Kew list as a variety of *L. japonicum* (Krameri), so different is it in appearance and constitution from that elusive species. Dr. Wallace, however, was strongly of that view, albeit *L. Brownii odorum* loves lime and *L. japonicum* detests it. *L. Brownii odorum* is reputed to be of easier cultivation than *L. Brownii*, less susceptible of frost and more indifferent to winter wet. It is a desirable plant, with a general resemblance to *L. Brownii*, but not so graceful in growth. The blooms appear a fortnight or three weeks later than *L. Brownii*. The flower tubes are shorter and less deeply stained with purple outside.

***L. candidum*,** the Madonna Lily, has been the source of widespread despair among horticulturists for more than forty years, owing to the

ruin wrought upon it by that deadly fungus *Botrytis cinerea*. If *L. auratum* be the most gorgeous of the genus, the Madonna Lily must be admitted as the loveliest, and no amount of pains should be grudged to purge it of the parasite. In some gardens, often very humble ones, it flourishes and increases as vigorously as a German Iris; in others, the most assiduous treatment has failed, season after season, to preserve it from the pest. Unlike other Lilies, it sends up luxuriant verdure in the autumn, which remains unhurt by frost till the spring, when vigorous flowering stems make their appearance full of promise for midsummer; until suddenly the enemy makes its presence felt, the stem-leaves, beginning from the bottom, wilt and shrivel, growth is arrested and instead of five or six feet of sturdy stem, clothed with shining, light green leaves and carrying twenty to thirty trumpets of fragrant alabaster, nothing is left but a blighted stalk, disfigured by shrivelled foliage and bearing three or four blemished blossoms. Whereas *Botrytis* is the most insidious and inveterate plague with which the cultivator of Lilies has to contend, and whereas nearly every species of Lily is more or less subject to its attack, this may be a fitting place to describe the most hopeful precautions to be taken against it. The fungus first appears on the leaf as a yellowish brown, oblong blotch, as if some mordant liquid had been dropped on it, within which blotch a lens reveals a number of black dots of fructification. Mr. Grove having waged successful war against the enemy, I may quote his prescription: "At the first sign of the malady the plants attacked should be sprayed with a solution of 10z. of sulphide of potassium to 2½ gallons of water, the dose being repeated daily, and all uninfected Lilies near by should be sprayed with Bordeaux Mixture or Evans' Aseptic Solution. If the disease gains ground notwithstanding the spraying, the proper course to pursue—if an heroic one—is to cut down the affected Lilies and burn every scrap." In short, "let us spray"—and if that fails, "let us pray"—that in time the Madonna Lily will recover such strength of constitution as will enable it to resist *Botrytis*; just as the Hollyhock, which a few years ago seemed to be on the verge of extinction under the ravages of *Puccinia*, once more adorns our borders with its many-coloured spires.

Every living thing, animal or vegetable, is the host of parasitic organisms. So long as the host remains in perfect vigour, it can usually entertain such guests without appreciable injury; but so soon as its vitality flags under some adverse condition, such as excessive wet, untimely frost or improper cultivation, the parasite gets the upper hand, multiplies inordinately and vanquishes the host. Therefore, while resorting to spray and other palliatives to keep *Botrytis* at bay, our chief concern should be to provide the Lilies with the conditions of

soil and situation most suitable to their wants. The wants of the Madonna Lily are few and simple. A native of the Mediterranean region, growing wild on the rugged tract of limestone that divides the Adriatic from the Ægean Sea, it is far more likely to suffer in our gardens from overfeeding than from famine. In fact, the finest display is often to be seen in some farmhouse or cottage plot, where the bulbs have grown crowded and uncared for, it may be for generations of men, while dismal failure dogs all manner of coddling and coaxing in a fully manned and richly manured garden. The best advice that can be followed is, first, to secure perfect drainage; next, to plant the bulbs shallow, not more than

in September. Lastly, let him who is lucky enough to have thriving clumps of this peerless Lily leave them alone. There is a variety of the Madonna Lily called *robustum*, which, as its name implies, is sturdier than the type, and may prove less liable to disease. I planted fifty bulbs of this variety in September, 1913, and these have flowered splendidly, without a trace of disease. Another variety named *speciosum*, with black stems, is well reported of, but I cannot speak from experience thereof. A third variety with narrower sepals than the type is much inferior, and therefore to be avoided. As for the double-flowered Madonna Lily offered in nurserymen's lists, it is an ugly abomination.

L. japonicum.—This is usually known in gardens as *L. Krameri*. It is a lovely thing, but my own experience of purchased bulbs is most discouraging. A few large blossoms of delicate blush pink have been produced in the first season, after which the bulbs have disappeared. I admit, however, that I gave up attempting to grow it several years ago, before I had learnt from experts the right way of treating imported bulbs. It is possible that if the bulbs were placed in large pots on arrival, deprived of flower-buds in the first season, and in the second season planted not less than 8 inches deep on sandy soil without lime, on a bank steep enough to ensure rapid drainage, this Lily might prove more permanent than it has done hitherto. The only other chance of keeping it is to raise it from seed, which it is said to ripen freely. Bulbs of this and other species obtained in this manner are not exposed to the debilitating effects of rough handling, packing and other adverse incidents of the import trade, and *Kramer's Lily* is so beautiful as to be worth waiting for during its growth from seed.

L. longiflorum.—This is imported in millions for pot culture, and is usually sold as the Bermuda Lily. Every florist's shop teems with this beautiful flower. It is usually reckoned not to be hardy in this country, and that is true enough of the variety cultivated in Bermuda, whence British dealers have hitherto drawn their chief supply. But the wild type is probably a native of China, and some of its varieties have proved patient of the vicissitudes of our insular climate, at

least in the South and West. The more robust of these varieties comes from the Liu-Khiu Islands, and is distinguished as *L. longiflorum formosanum*. Planted deep in very gravelly soil, enriched with leaf-mould, sand and wood-ashes, on a steeply sloping bank, this Lily comes bravely through the winter with me, and flowers freely on stems between 2 feet and 3 feet high. A thick covering of leaf-mould is advisable to protect the bulbs from frost, of which they have no experience in Liu-Khiu. If it grew but a foot or two higher it would be a formidable rival to the Madonna Lily.

HERBERT MAXWELL.

(To be continued.)

THE MADONNA LILY (*LILIUM CANDIDUM*), WITH A BACKGROUND OF DEEP GREEN SHRUBS.

4 inches or 5 inches from the surface, but with care to break up the soil to a greater depth below them. The soil should be the reverse of unctuous, with a liberal admixture of ground limestone, chalk or old mortar rubbish. Overhead shade is objectionable, but the proximity of trees is of advantage, for this Lily thrives well among tree roots, relishing the dryness which these ensure. In one respect the Madonna Lily differs from nearly all other Lilies, in that the bulb never rests, but starts into fresh growth immediately after flowering. Perhaps that is the effect of our wet autumns; but, anyhow, it imposes on us the necessity to get all planting or transplanting accomplished early

SEASONABLE NOTES ON CHRYSANTHEMUMS.

Propagation.—Early in the New Year, cultivators of these plants will be anxious to put in large batches of cuttings. Neither in greenhouses nor in frames is there much vacant space during the winter months, and so it is advisable to economise in this respect as much as possible, and only insert the naturally late and November flowering varieties. Cuttings of the early sorts should be dealt with immediately the first batches are rooted sufficiently to take out of the propagating-frames. The wise cultivator will have procured and stored in a cool place a nice quantity of cutting compost, some clean, dry pots and crocks, also new labels.

The Best Cuttings to Select.—A weakly cutting may be strengthened, but much valuable time is lost and it requires more attention than a strong one. Rather than be content with weakly cuttings, cultivators should purchase good ones from firms who advertise them for sale, as they treat the old roots specially for the production of sturdy suckers. Of course, more cuttings must be inserted than are actually required to make up for losses. The best cutting is one growing as a sucker through the soil—one that is 3 inches or a little more in length when severed at the soil level; it must be of medium thickness, not soft and very sappy. The sappy-stemmed cuttings damp off sooner than those that are firmer and harder. If cut much below the soil level, the cutting will not form roots quickly, and the resultant growth will not be free. The best policy in such cases is to wait until the suckers have grown long enough to sever above the soil, as time will not be lost, but gained, owing to roots forming quickly and progress afterwards being more satisfactory.

Making and Inserting Cuttings.—Sever the stem one-eighth of an inch below a joint and remove the leaf from that joint. When once roots are formed, it is very important that they are not unnecessarily disturbed afterwards, especially if the plants are to be grown for the production of large blooms or as big specimens. With such work in view, make use of small but deep pots, and strike one cutting in each. Very fibrous loam, flaky leaf-soil and coarse sand in about equal proportions form a nice compost. Place one crock in each pot, then some leaf-soil on it, before filling up with the general compost. Let the latter be of medium moisture when used, and make the cuttings firm in it. A small frame placed on a greenhouse stage forms an ideal propagator; boxes covered with squares of glass will answer the purpose well, but damping of cuttings is always more general when the glass is fixed on a flat top. Form a miniature roof to

the box and place the glass so that it has an angle of 45° or sharper still, and loss from internal moisture will be less. Remove the glass every forenoon for about one hour, and wipe it dry both morning and evening. Having once watered in the cuttings, be careful not to keep the soil too moist afterwards.

In an early issue, with the Editor's permission, a select list of varieties for various purposes will appear. The following are new and very fine ones that should be obtained at once by cultivators who wish to score successes during the present year: Yellow Mrs. Gilbert Drabble, a grand variety of fine form, propagate now; Queen Mary (white), Mrs. Gilbert Drabble (white)—these are late flowering and require a long season of growth; Lord Kitchener (ruby crimson), General Joffre (another grand crimson), General French (clear terra-cotta), Master Mortimer (delicate rose), Daily Mail (yellow, narrow florets), William Vert

ON WALL GARDENING.

SO many conflicting elements of charm and—let it be admitted—of disillusionment no less are to be found in wall gardening that it is no great wonder if a fierce battle of opinion should be waged with regard to its merits or demerits. Yet we are fain to believe that it was a happy inspiration which suggested how some old walls might be improved by wisely encouraging vegetation upon them, and how others might even be built with a view to planting. We pause in admiration, perhaps, before some dilapidated wall fringed with the dainty greenery of Maiden-hair Spleenwort, or catch sight of a stray garden plant which has found a home for itself in a crevice of mouldering brickwork, whence it looks down, exultant in its fulness of blossom, upon its kindred

PRUNUS TRILOBA FLORE PLENO, A BEAUTIFUL HARDY SHRUB WITH PINK AND WHITE FLOWERS.

(chestnut crimson), Mrs. James Gibson (mauve pink), Mrs. C. Farrar (bronzy buff) Mme. T. Morel (apricot), and Maud Lousada (rosy mauve) AVON.

A BEAUTIFUL HARDY FLOWERING SHRUB.

THE accompanying illustration represents a fine plant of *Prunus triloba flore pleno*, one of the most beautiful of all hardy flowering shrubs. Fortunately, it will thrive in almost any good garden soil, and does equally as well grown as a bush in the open as when trained to a wall. It may be planted at any time during the winter, and once it has filled its allotted space, should be pruned hard each spring immediately the flowers have faded. These are borne on the young wood, hence by removing this promptly at the time stated vigorous new shoots are produced for flowering the following year.

H. of the border, whose very luxuries of easy living, maybe, have made them rank of leaf and sparing of flower. So it is that we find Nature herself pointing the way, and we shall not go very far wrong if we patiently follow her footsteps. Generally speaking, the temptation to an enthusiast is to overdo the planting. A wall, even one that is prepared, ought not to be regarded as a sort of perpendicular flower-bed, as some people seem inclined to think, for it loses much of its characteristic beauty as soon as it becomes too thickly overgrown. Age-worn and weathered stone and brickwork have a charm and colouring all their own which it would be folly to hide, but which, nevertheless, may be greatly enhanced by the skilful addition here and there of leafage and flower. Yet it is not always easy to strike the happy mean. It fell to my lot once to see a design prepared in all good faith for the purpose of showing an easy way out of many difficulties besetting

wall gardening. The sketch was intended to be a model pattern for a terrace garden, and represented a somewhat pretentious erection backed by a 10-foot wall, pigeon-holed in rows by the omission of a brick at regular intervals, the pockets being arranged quincunx fashion. The plan certainly had the merit of making the most of the wall surface. But the charm of a planted wall is not to be wooed or won by any such simple rule of thumb. The growth upon it must be spontaneous, or, at any rate, so cunningly regulated as to appear to be so.

Boundary walls for the most part are less adaptable for planting than retaining walls, which

In the same garden a branch of Winter Jasmine has rooted of its own accord into the coping of another boundary wall, where its welcome stars serve to lighten the dreariness of flowerless January. The grey-green of a plant of homely Sage—a stray seedling lodged by chance—has been known to produce a delightful bit of colour contrast against the mellowed red of an old brick wall. How shrubs of naturally strong growth find sufficient nutriment in the seemingly inhospitable quarters so offered, it is difficult to say, but so it is; and not only do they sprout, but grow and live for years, forming pictures of their own sweet will which are hard to copy and harder still to beat.

that capacity it may be seen, in fullest beauty, clinging to the sun-dyed brick of crumbling Roman ruins; but it is not an uncommon garden shrub in the West of England. Once established on a sunny wall, it will always be treasured, so slender is it in its growth, so little aggressive, yet so laden in early summer with clusters of soft yellow Pea flowers, just touched and pencilled with russet red. It may be of some practical use, by way of reminder, to name a few of the plants, other than shrubs, which have done well in this locality. A colony of Catmint (*Nepeta Mussinii*), with hoary leaves and a wealth of grey-blue flowers in its season, is rightly placed just leaning over the

A RETAINING WALL VEILED WITH FLOWERING PLANTS.

naturally foster plant growth. One of the prettiest of small plants for a boundary wall is *Vittadenia trilobata*, whose cheerful little Daisy flowers, changing from white to deep pink, smile at us faithfully from spring to late autumn. It has a natural affinity even for a mortared wall, where it will find a foothold somehow, and quickly makes little colonies of itself without any fuss. In some gardens *Erinus alpinus* takes freely to the upright position and needs scarcely any rooting space; but here it shows a decided preference for flat surfaces, and sows itself delightfully into the joints of rough stone steps. It is never a surprise to see Snapdragon or Wallflower or Ivy-leaved Toadflax flourishing on a boundary wall; but there are other plants, apparently quite unsuited by habit for such situations, which make themselves equally happy there when accident gives them the chance, and sometimes we get an unexpectedly good effect. Take shrubs, for instance. No one would dream of planting *Ribes* on the top of a kitchen garden wall; yet five minutes' walk would bring me to a spot where little bushes of the red-flowered Currant—of low stature indeed, but rosy with flowers every spring—brighten the summit of such a wall.

Where dry walling holds back a considerable body of soil the case is different, and shrubs of a certain type become valuable auxiliaries. Some of the smaller-growing *Cistus*—notably *C. florentinus* and *C. lusitanicus*, a miniature Gum *Cistus* little grown, which has crimson-spotted, cupped petals—are especially suitable. Rooted cuttings of these were inserted in the joints at the top edge of a retaining wall in my own garden, and have thriven amazingly. Their fault, if anything, has been a superabundant vigour, which has made it necessary bodily to cut down one here and there, both stubs and roots being too firmly embedded to allow of entire removal. The stumps, notwithstanding, have broken afresh, so that these cut-down bushes will eventually flourish again instead of others which, later on, must receive the same drastic attention. Some of the New Zealand *Veronicas* of naturally dwarf habit, favoured by our mild Sussex coast climate, have also done well in a like position. Being evergreen, both *Cistus* and *Veronica* are peculiarly suitable for wall planting in the Southern Counties. One other native of South Europe—*Coronilla Emerus*, well known to our forefathers as Scorpion Senna—occurs to me as an ideal wall shrub. In

the corner of a retaining wall, and is very charming; but it quickly dies out and has to be renewed. *Lithospermum prostratum* comes earlier in the year—one of the earliest, in fact, to start flowering—and is a veritable gem with its boss of gentian blue against our greyish yellow sandstone. The confined root space keeps it from straggling. A form of *Phlox Stellaria* known, I believe, as *P. lilacina* is one of the most delightful of our spring plants, and is apparently not very familiar even to good gardeners, who always notice its profusion of flower as it hangs its trailing stems over the stones. *Genista sagittalis*, which has curiously flattened and winged stalks, with scarcely any leaves, is at all times distinct, and very decorative about midsummer when full of its golden tufts of flowers. Some of the Plumy Saxifrages, again, e.g., *Saxifraga pyramidalis* and *S. macnabiana*, have done well here, while for less good positions a handsome hybrid of the London Pride type, known as *S. Colvillei*, is invaluable, and takes care of itself. For rougher positions still—especially low and damp ha-ha walls—Ferns of the commoner sorts are picturesque; but beware lest

they take possession of any wall where choicer things are invited to grow. This is not a Fern locality, yet Male Fern, Buckler Fern and even Brake have become a nuisance, so difficult are they to remove when they are in the wrong place.

One comes to the conclusion in the long run that in wall gardening we must be content, in a measure, to let things have their own way. In most parts of a garden this is bad practice—the haphazard system seldom works out well. It is always better, no doubt, to have a scheme in view even for a wall, and to control the growth upon it as far as possible; but it is wise to be prepared for unruly subjects which will not by any means be governed. We may try again and again to produce an effect which seems delectable to our mind's eye, but some accident of aspect—of shade or exposure, of dryness or damp—frustrates the most nicely calculated intention; while an alien intruder, a Mullein or wandering Foxglove, perhaps, finds its way in and ends by conquering our affections by dint of sheer audacity. It may even be that it is this very quality of waywardness which adds such intense interest and enjoyment to any attempt that may be made at wall gardening. K. L. DAVIDSON, in *Country Life*.

SOME GOOD DWARF POLYANTHA ROSES.

DURING the last few years a good deal of attention has been given to the Dwarf Polyantha Roses, a race that is particularly useful for filling large beds, owing to the fact that the plants make neat, compact bushes, many of which are almost evergreen, and their freedom of flowering. Late in the autumn, when visiting some large Rose nurseries in the Midlands, I was reminded of the value of these Roses for autumn effect, row after row of goodly length being almost hidden with the large clusters of small, rosette-like flowers. Four varieties were particularly noticeable, these being Jessie, Phyllis, Orleans and Katherine Zeimet. The first named is the most beautiful of all, the blossoms being deep glowing crimson-scarlet in colour, yet not sufficiently glaring to be objectionable. Phyllis has dainty rose pink flowers, a colour that Orleans also shares, but in the latter variety the blossoms are rather larger and the bushes a little taller. Although Orleans is very beautiful in autumn, the blossoms bleach rather badly during the hot days of summer; hence some care would need to be exercised in using it in very sunny districts, unless an autumn display only is required. Katherine Zeimet has pure white flowers, which are deliciously sweet-scented, a character that the others named unfortunately do not possess in any great degree. Having once seen the beautiful colour effects that these little Roses will produce, it is difficult to understand why they are not more freely used in large lawn beds in place of the heterogeneous mixtures of bedding plants that one too often finds in many of our large gardens. A circular bed, some ten yards or twelve yards in diameter, might be thickly planted with Jessie, leaving a yard or so in width at the edge for Katherine Zeimet. If ordinarily well grown, the bushes would commence to flower early in July and continue right through the late summer and autumn until frosts put a check on their career. Last year in an Essex garden I gathered good sprays from Jessie at the end of November, long after the ordinary bedding plants had been destroyed by frost. Phyllis or Orleans could be planted in association with Lavender, either as a margin to stone pathways, at the top of retaining walls, or in large beds, in the proportion of two Roses to one of Lavender, the latter to be the common steel blue flowered variety. These colours create a delightful harmony, which is scarcely broken even when the Lavender flowers are past, the glaucous grey tint of the foliage having an almost similar effect. Although the initial cost of planting beds with these Roses, or Roses and Lavender, will be rather more than that of Geraniums and other soft-wooded plants, this will be more than compensated by the number of years that the Roses last. Apart from aphides, the Dwarf Polyantha Rose is not usually seriously affected by other ills that the Rose is heir to. H.

CRINUMS AT MICHAELMAS.

As the year approaches its close, the fewer flowering things that remain, or that may still be looked for, are all the more precious. It is well to remember how late in the year Crinums are in beauty. The photograph was taken on Michaelmas Day, and the plants had yet another fortnight of beauty, so carrying on their duration of bountiful bloom to near the middle of October. Where there exists, or can easily be made, a sunny bank of very deep, light soil, these lovely things may be had in perfection. If there is a wall or some such protection at the back, it is all the better. Much the same conditions suit the great Tree Poppy, Romneya Coulteri, and a good length of bank with the two kinds of plant intergrouped would have a fine effect. G. JEKYLL.

THE BEST APPLES AND PEARS FOR MIDLAND COUNTIES.

I HAVE read with interest various letters that have appeared in THE GARDEN relative to the best kinds of Apples and Pears. Perhaps a few notes as to one's experience in an East Midland county

and Son, and as an October Apple I know of nothing to touch it. All my friends who have once tasted this Apple desire to renew their acquaintance; but, strangely, I have never seen the tree elsewhere than in my own garden. The Apple must not be confused with the various Golden Pippins, and if any of your readers wish to plant this kind they should make sure they get it. The fruit is best when taken fresh from the tree, and will keep good a full month or longer.

Another little-known Apple and a new one is St. Everard. I have had the tree for two or three years, but it gave me a few Apples last year for the first time. They were ripe at the end of August, handsome and excellent.

I have not been fortunate in finding many other dessert Apples that I care for, but Cox's Orange Pippin makes one very fastidious. I thought Allington Pippins were going to be a real find, but the fruit was cold and sour and not worth growing.

As to Pears, different soils affect trees so much that many kinds valuable in other districts are useless here. My selection, after a long experience, is: Jargonelle, Williams' Bon Chrétien, Beurré Hardy, Emile d'Heyst, Beurré Superfin, Winter Nelis, Dana's Hovey and, above all, Doyenné du Comice. I have recommended this latter Pear so much that it is now abundantly grown

CRINUMS FLOWERING ON MICHAELMAS DAY IN MISS JEKYLL'S GARDEN AT MUNSTEAD WOOD.

would be of interest to readers. I have for the last thirty years tried a great many kinds of Apples and Pears, and have found, very often to my sorrow, that many much-vaunted kinds are of no value in this district. As regards Apples, I have come across few new varieties that I think worth keeping, and I find myself thrown more and more upon the famous Cox's Orange Pippin. To get this fruit to perfection, the tree needs growing in the full eye of the sun and the fruit carefully thinned. The finest fruits I have grown have been on espaliers, and last year two Apples weighed 14½ oz. An Apple that I think one of the very best is Pine Golden Pippin. This came from Messrs. Rivers

all over the district, and the best quality fruits I have ever eaten were some given me by a friend, grown on a wall in stiff clay. Many years ago I planted a tree of Duchesse d'Angoulême and a "Williams." The Pears had no flavour at all, and I was about to cut the trees down when I read somewhere that the fruit of Pear trees improved as the trees grew older. This I found to be true. Winter Nelis is a splendid Pear, but I get a very scanty crop. I have two trees on a south wall, and an espalier, which produce an abundance of bloom, but scarcely any sets. I should be grateful if anyone can give me a hint as to the remedy. HUNTS.

GARDENING FOR BEGINNERS.

HOW TO FORCE RHUBARB.

FORCED Rhubarb is much appreciated during the early weeks of the New Year. At that time the fruit of our orchards is becoming scarce, and those who are responsible for maintaining the supplies of the kitchen naturally look round to see how the strain upon Apples, Pears and such-like fruits may be relieved. Fortunately, the forcing of Rhubarb is not by any means difficult to carry into effect. Methods of forcing are varied and interesting, and many different modes are practised with equal success. Some growers make a point of preparing a small border in a southern aspect, if possible under the protection of a wall, hedge or close fence. More often, however, roots with promising crowns are lifted and planted under glass, in frames, or in a Mushroom-house, where it is an extremely simple thing to ensure supplies of good quality.

Beginners may be in some doubt as to when the roots should be lifted for forcing purposes. They may be lifted at any time after the leaves die away in the autumn. Those who are adept in raising Rhubarb under cover as we have suggested prefer to leave the roots exposed in the open to a slight frost or two before placing them in their forcing quarters, as they invariably break into growth better when once they are placed in heat. Prospects of a satisfactory forcing of this crop are improved when the lifted roots are very strong and not more than two or three years old. That readers may understand what a vigorous root is, a typical specimen is portrayed in Fig. 1. In ordinary circumstances we should disturb the soil round about the roots as little as possible; but, for the purpose of photographing, the soil has been removed.

I have already said there are numerous places in which the roots or crowns can be planted for forcing, and there is no more useful place than under the stage of a warm greenhouse where the temperature can be maintained at from 55° to 60°. It is almost necessary, however, that the quarters should be made dark, as growth is then more rapid. A warm cellar can be utilised for the same purpose with advantage, especially for supplies that are wanted in January and later. Those who possess a Mushroom-house have an immense advantage over other growers. There is no more suitable place than this. The conditions that usually prevail there are all that could be desired, and the crop seldom fails when properly looked after. The floor of the Mushroom-house should be covered with about three inches of good soil, and the roots then adjusted in position, working some light soil between and around them to complete the planting. It is important to remember that when forcing Rhubarb, the roots must be maintained in a moistened condition. Especially is this necessary when the conditions are rather warmer than usual; frequent sprinklings with tepid water will assist very materially to promote the well-being of the crop.

To follow the earliest supplies under glass and from other quarters, beds outdoors should be utilised to their fullest extent. Beds and borders made up under a wall or a close fence facing south, as already mentioned, are excellent situations for subsequent supplies, and from such quarters a second crop should be obtained. This is perhaps the simplest way of all of forcing Rhubarb, as splendid crops may be obtained with the minimum of trouble. When Rhubarb is forced in the open, the grower may utilise the services of coverings of various descriptions—in fact, anything that will cover the roots and that has sufficient head room.

For raising crops of some of the more vigorous and taller-growing Rhubarbs, such as Hobday's Giant, I prefer to use empty Apple barrels. These should have the ends knocked out, and the better end preserved intact for covering purposes. In Fig. 2 an Apple barrel, as used for forcing these taller-growing Rhubarbs outdoors, is shown. Here it will be observed the barrel is placed in position over the Rhubarb root, with the lid slightly tilted to show it is not fixed, and can be adjusted after inspecting the crop. The barrel is partially embedded in warm stable litter, which will encourage the roots to start, and subsequently, if needs be, the whole barrel can be covered with the same littery material. Leaves and stable litter used in conjunction are better, as the heat does not then get too fierce.

FIG. 1.—A STRONG RHUBARB ROOT THAT IS SUITABLE FOR FORCING.

The coverings should be tested occasionally, so that the latter condition may be avoided. D. B. C.

THE WINTER TREATMENT OF BORDER CHRYSANTHEMUMS.

ALTHOUGH in most districts these plants are hardy enough to withstand ordinary winters without any protection whatever, there is always a possibility that slugs and wet, with severe frost, may cause so much damage as to render the plants practically useless. For that reason I always find it advisable to lift the old stools and place them in a cold frame, or, failing that, a warm and dry corner of the garden. If not already done, no time should be lost in attending to this work, as already the sucker-like growths are pushing above the soil. To prevent the depredations of slugs, and at the same time ensure perfect drainage, I make up a bed, 3 inches thick, of stale coal ashes and on these place the lifted stools closely together. Then a mixture of ashes, soot and fine sandy soil is shaken between them so as to make the whole moderately firm. If in a cold frame it is neither necessary nor desirable to have the light on, except in extra severe or wet weather, and even then ample ventilation must be afforded, as it is essential that the new growths be as sturdy as possible.

Old stools treated in this way will give a bountiful supply of cuttings for rooting in pots or boxes during February where that method is favoured. A system that I have adopted with border Chrysanthemums for some years, and one that answers as well as it is simple, is to lift the old stools from their winter quarters about the second or third week in March, and pull off the young growths with a sharp downward jerk. Nearly every one will come away with several young roots attached, and each is planted where the subsequent plant is intended to flower. In a few days they recover from the check, make new roots and quickly establish themselves. Then, about the end of April, when growth is fully active, the top is pinched out of each, the result being a nice bushy plant by the autumn.

A. B. Essex.

FIG. 2.—AN OLD APPLE BARREL SURROUNDED BY LONG MANURE IS USEFUL FOR FORCING RHUBARB OUTDOORS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Strawberries.—A batch of plants may now be placed indoors. Choose those with large single crowns, carefully remove a little of the surface soil with a pointed stick, and top-dress with a mixture of loam, manure from an old Mushroom-bed and wood-ashes. See that the drainage is clear before bringing them indoors. A shelf in a vinery or Peach-house which has just been closed will suit the plants for the first few weeks. Keep the foliage clean by vigorous syringing whenever the weather is fine, and never allow the plants to become dry at the roots.

Young Vines.—If these are to be planted and are to be procured from the nurseryman, no time must be lost in doing so, as the rods will require to be cut back to five or six buds. This should be done before the end of the present month, or the Vines are likely to bleed badly. Young Vines may be propagated now from eyes inserted in small pots or turves. Place them on a hot-bed in a warm, moist house and water carefully till growth is active.

Plants Under Glass.

Begonia Gloire de Lorraine.—As the plants pass out of flower reduce them to about half, place them in a moderately warm house for two or three weeks, and give water sparingly to induce the plants to rest. They may then be cut right down and placed in a warmer house and frequently syringed, where they will quickly throw up strong cuttings for propagating.

Roses in Pots.—To keep up a good supply of blooms, a batch of plants should be placed near to the glass in a light structure at fortnightly intervals. A temperature of 50° will be quite high enough till the buds begin to show. Even then too much artificial heat must not be given.

Lily of the Valley.—To keep up a supply of these flowers, retarded crowns must be used till the end of the present month. A batch must be placed into heat every fortnight or three weeks, according to the demand. Ordinary crowns may be used after this month, but these are much more difficult to manage, and the least cultural error may cause disappointment. Clumps dug up from the garden are easily forced on a hot-bed in a heated frame. Keep the glass well covered till the flower-spikes are well above the ground.

The Flower Garden.

Sweet Peas.—No time must now be lost in sowing a batch of seeds if not already done. Sow two or three seeds in small pots and place them in a cool pit. When the plants are through the soil, remove them to a cold frame and encourage sturdy growth by giving plenty of air whenever outside conditions will permit.

Early Flowering Chrysanthemums.—There is now a wide range of beautiful varieties suitable for growing in the flower garden. The best means of propagation is by cuttings, which may be inserted now if they are available. Insert them in a sandy compost in boxes and place them in a heated pit till they have rooted. They may then be placed in a cold frame.

The Rock Garden.—Any alterations or additions to this part of the garden should be accomplished as soon as possible, so that the planting of dwarf shrubs or other hardy subjects may be done. The making of a rock garden is a very fascinating phase of flower gardening, and to my mind the point which needs most consideration is the choosing of the site.

The Hardy Fruit Garden.

Orchard Trees.—These must have their annual pruning or thinning. When trees have assumed very large proportions, all that can be done is to thin out the branches where they have become too dense, especially those which are crossing each other. This annual thinning of large orchard trees is just as necessary as the pruning of trained trees in other parts of the garden. Liquid manure from the farmyard, which is usually very plentiful at this time of the year, should be thrown over the rooting area of old-established trees.

Pruning.—The pruning of all fruit trees which are near the vegetable quarters must be done as

soon as possible, so that digging operations may be carried out without delay. Gooseberries need thinning severely, cutting out an old branch here and there to make room for young growth. Black Currants may have all the old fruiting wood removed if there are sufficient young growths to furnish the bushes. The side shoots on Red and White Currants must be cut well back, the leading growths being left a few inches for extension.

The Kitchen Garden.

Onions.—Many growers now cultivate a portion of this valuable crop by sowing seeds in boxes under glass, planting the seedlings out in the spring. For this purpose seeds should be sown during the present month. Sow thinly in a fine compost of loam and leaf-soil, and place the boxes on a shelf in a vinery or Peach-house which has just been started.

Cauliflowers.—The autumn-sown plants must be regularly attended to in the matter of watering, giving them an occasional application of liquid manure. Admit plenty of air to the plants during favourable weather. A sowing of an approved early variety may be made now in boxes and placed in a moderately warm house.

Forcing Vegetables.—Place successional batches of Asparagus, Seakale and Rhubarb into the forcing quarters at regular intervals.

French Beans.—Where plenty of convenience is available, batches of these may be potted up at intervals of ten or twelve days. Plant five or six seeds in a 7-inch pot in a rich compost. They require plenty of heat and moisture, and a position near to the glass. A dwarf variety, such as Osborne's Forcing, is most suitable for the earliest crops. The Belfast is also an excellent variety for forcing.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Seakale.—Strong crowns should be lifted and are easily forced in the Mushroom-house, or may be planted five in a 10-inch pot and covered by an inverted pot of the same size and placed in a warm house, taking care that the top pots have their holes perfectly closed.

Endive and Chicory make good substitutes for Lettuces during the winter, and should be put in to blanch quite a fortnight before the date they are required. These likewise could be brought along in the Mushroom-house.

Tomatoes.—A main sowing will be made at this time of a reliable and proved variety. Sow thinly and evenly, so that the small plants may readily be separated when it is time for them to be potted off singly. A shelf near the glass in a warm house will suit them until they are 6 inches or so in height. After this stage they will grow more sturdily if kept in an intermediate temperature.

The Hardy Fruit Garden.

Autumn-Fruiting Raspberries.—These are a valuable addition to those who have to maintain a supply of dessert in great variety over a long period. Unlike summer-fruited sorts, they produce their fruit on the current year's growth. This makes it necessary for all the canes to be cut down now. A new plantation of these could be made at the present time. Choose a sheltered position and plant in rich soil, if possible adding new loam with plenty of lime rubble.

Plants Under Glass.

Chrysanthemums.—All cuttings of Chrysanthemums that are to be grown in pots should be put in during this month. Any plants that up to now have failed to produce young growths should be put in a warm house until sufficient cuttings have been obtained.

Tree Carnations.—Houses devoted to these plants should be kept a little drier than during the summer. A night temperature of 48° to 50° should not be exceeded, or weak stems and split calyces will result. Opinions differ as to the best time to propagate. Here we find the best plants are produced from cuttings inserted in January. A reliable method is to dibble the

cuttings thickly in 4-inch pots filled with pure sand in a moist state, and put them in a case in some cool house. If bottom-heat is used, it must be very gentle.

Bulbs.—A number of these can be placed in heat each week to keep up the supply of cut flowers.

Flowering Shrubs.—To keep the flower house gay, Lilacs, Azaleas, Pyruses, Prunuses and Wistarias must be brought along in heat. All the foregoing force very readily.

Begonia Gloire de Lorraine.—If the early flowered plants were partly cut over during December and slightly rested, they ought by now to have produced enough cuttings for the earliest batch. These should be dibbled in pans of very light flaky leaf-mould and coarse silver sand, and plunged in a propagating-case with a brisk bottom-heat.

Pot Roses.—Slightly prune a batch of these now and place in a house with a temperature of 55°. Careful ventilation, avoiding a draught, will to some extent prevent mildew.

Fruit Under Glass.

Vines.—All Grapes should by this date be cut. If not required for immediate use, they can be bottled, which will keep the berries in a plump condition for some time to come. This operation simply consists in filling bottles with water, to which add a few nodules of charcoal. Then place the bottles in a slanting position on the edge of a shelf in the fruit-room, so that the bunches may hang clear when their stalks are put in the water. Look over the bunches frequently for bad berries and keep the bottles full of water.

Resting Vines.—If we except the early vinery, all Vines should be at rest during this month. Plenty of air must be kept on constantly, only closing the ventilators during frost. Pruning should be completed and the vineries given a thorough scrubbing.

Renovating Vine Borders.—Greatly improved vigour and finer fruit can be had by renewing Vine borders when they begin to show signs of exhaustion. The present is a suitable time for this operation.

Strawberries.—Another batch of these may be brought indoors to succeed those started during December. They benefit from a rich top-dressing. If room is not to be had on vinery or Peach-house shelves, they can be brought along very nicely if plunged in a mild hot-bed of stable litter and leaves.

Pot Figs.—Where very early Figs are required, trees in pots will be found to mature fruit quicker than planted-out specimens. A number of these may now be put in heat, and will be greatly assisted if plunged in a gentle hot-bed.

The Flower Garden.

Naturalised Bulbs.—If any leaves remain where these are growing, a final brush up should be given now, so that there will be no danger of injuring the young growths once they appear above the ground.

Stakes and Canes.—Fine opportunities for overhauling these are offered during stormy weather, which prevents the ordinary outdoor work being proceeded with.

Pentstemons.—A great variety of colour may be had during the autumn if seed of a good strain is sown now. For summer bedding the plants are generally propagated by cuttings put in cold frames during the autumn. These must not in any way be coddled, but should be protected during frost. George Home is still perhaps the best all-round variety.

Violas.—These plants which were struck during the autumn will be found to survive the winter much better if the lights are removed when there is no danger of frost or rain. As the Viola is a perfectly hardy plant, it should not be protected except during very severe weather.

East Lothian Stocks.—Unlike Ten-week Stocks, these fragrant flowering plants require a long season of growth, and should be sown now in seed-boxes. Place them in a warm greenhouse or vinery just started, and remove to cooler conditions when their seed leaves have developed.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

THE IDEAL CATALOGUE.

AS the Daffodil is my favourite flower, naturally one of my pleasant anticipations every week is opening my GARDEN to see if there is any article about my beloved flower. Alas! of late I have had many disappointments. Please ask the Rev. J. Jacob not to reserve all his efforts for the "Daffodil Year Book," but to write occasionally in THE GARDEN about the Daffodil. Lately he seems to have confined himself mainly to Tulips. [See his article last week.—ED.] In December 19 issue, page 611, however, "Somerset" has contributed an interesting criticism of a Daffodil catalogue.

May I state my little grievance with catalogue compilers? Not being overburdened with riches, I can only afford to grow a few of the better sorts, and I want only those that are good doers. Of course, if they are up to exhibition form as well as possessing good constitutions, so much the better. My grievance with "X. and Sons'" catalogue, and most other Daffodil catalogues that I know, is that they describe and mark the flower almost entirely from an exhibition point of view. They do not, I think, cater sufficiently for the numerous Daffodil-lovers who do not exhibit, but who like to grow a few sorts of rather higher class than princes and ornatus.

For example, all catalogues would give more "stars" to King Alfred, Ariadne or Homespun than to Victoria, Frank Miles or Torch; but I venture to say that the last three would prove more satisfactory to the ordinary grower than the former trio. Maybe King Alfred, Ariadne and Homespun are not so well suited for the North of England as the South. At any rate, they are not happy in my exposed garden in Westmorland. Perhaps, Mr. Editor, you will get someone to write on Daffodils suitable for the North as you have done lately with regard to Roses. [We will prod Mr. Jacob; he lives in North Shropshire.—ED.] Exhibitors may not like the perianths of Frank Miles and Torch, but these varieties are grand thrivers in the garden, and are fine as cut flowers. What matter if Victoria grown in the open is rather short in the stem! It has few other faults. By the way, are not some people carrying their love of length of stem and excessive height in flowers rather to extremes? They are apparently not satisfied unless their Sweet Peas have stems 2 feet long and they have to wire their Perpetual-flowering Carnations when cut for vases. The newer Violets have legs so long that they can hardly now be described as modest. I think, however, I see signs of a reaction setting in. Even Lord Kitchener (the soldier, not the Daffodil) now approves of bantam battalions!

I am rather rambling, so will return to my love, the Daffodil. That pretty little Daffodil Waterwitch would, I think, be improved if it had a shorter and sturdier stem. In my windswept garden more than half the flowers every year are spoilt by the stems being bent and twisted by the wind.

When I can attend Daffodil shows, I, of course, make notes of the various flowers that I would like to add to my small collection in the distant future when they reach a price I can afford; but I have no means of knowing whether such as Loveliness, Mrs. Robert Sydenham, Dosoris or Great Warley and others that I admire have good constitutions or not, and I cannot afford to buy a great many sorts and find out for myself.

An Irish dealer has made a beginning of adding to the description of some of the Daffodils that he deals in a note as to their constitution, "good" or "poor," as the case may be. Will the compilers of the ideal catalogues kindly do the same? We would not expect perfect agreement, as, of course, soil, climate, &c., will always play their part; but it would be a great help to an ignorant and bewildered Daffodil-lover like myself, and I fancy I am not "the only pebble on the beach."

J. R.

ROYAL HORTICULTURAL SOCIETY'S DAHLIA TRIAL AT DUFFRYN, NEAR CARDIFF, 1914.

THE society's trial of Dahlias from a garden decorative point of view was again carried out in 1914, by kind permission of Reginald Cory, Esq., at Duffryn, near Cardiff, and again proved a great success. As the trial on this occasion was confined to seedlings not yet in commerce, and any varieties offered for the first time in 1914, the trial was not so extensive as in 1913, though some two hundred and forty varieties were sent in, and the number of novelties was largely increased both from at home and abroad, showing evidence of a greatly increased interest in these trials. The Pæony-flowered section was the most numerous, no fewer than 110 varieties being represented. The Collarette section totalled forty-four, the Cactus thirty-three, the singles thirty-two, the decorative varieties seventeen, the Pompons three, and one Pompon Cactus. Unfortunately, the first week in September was very wet, with high winds prevailing day after day, so that many of the flowers were damaged and were not seen at their best. At the time of inspection, however, they were rapidly recovering.

The Pæony-flowered varieties are advancing, having much better stems than the older forms; but little, if any, improvement was apparent in the Collarette section. The Cactus varieties sent in were a decided improvement on those of last year. Unfortunately, many of them were making a second growth, thus hiding to a certain extent the first flowers. The decorative section had withstood the wind and rain best of all, and a considerable improvement was noted here in the colours, stem and freedom of flowering. The other sections did not contain anything that could be called better than the varieties already in commerce.

The £5 5s. cup, kindly presented to the society by Mr. Cory, was recommended to be awarded to Mrs. J. C. Vaughan, a Pæony-flowered form. Though its first flowers are all double, later in the season it develops a distinct eye.

The trial was admirably carried out, and gave evidence of the great care and attention that had been bestowed upon the plants by Mr. Cory, to whom is tendered the grateful thanks of the society and of all admirers of the Dahlia as a decorative garden plant. Awards were given to the following:

CACTUS VARIETIES.

Name.	Sender.	Description.	Height. Feet.
Astree.....	Cayeux & Leclerc	Rich, deep pink	4
Beauty	Stradwick	Pink, florets slightly twisted	5
Honesty	West	White, shading to pink	4
Louvain	Dickson & Robinson	Pale yellow, centre shading to pink	4½
Sophocles	Cayeux & Leclerc	Deep terra-cotta	3

COLLARETTE VARIETIES.

Name.	Sender.	Description.	Height. Feet.
Avon	Dobbie ..	Vermillion scarlet self, collar shaded lemon	3½
Doon	Dobbie ..	Bright scarlet self, lemon collar	2½
El Kantara	Cory.....	Cherry red, collar white	4
Louie Blackman.	Stradwick	Buff, suffused vermillion	4
Ruby	Stradwick	Vermillion scarlet and yellow, lemon collar	3½
Warspite	Stradwick	Crimson scarlet, collar shaded white	3

SINGLE VARIETIES.

Crawley Star ...	Cheal ...	Rosy pink.....	4
Oran	Cory	Crimson scarlet	3½
Stora	Cory	Rosy crimson, yellow disc, large	3½

PÆONY-FLOWERED VARIETIES.

Amber Queen ...	West	Amber, shaded orange	5
An. Schieber ...	Pätzner ..	Rich yellow	5
Beacon	West	Intense scarlet	5½
Berlioz	Riding ..	Old gold, suffused salmon	5½
Beethoven	Riding ..	Amber	3½
Dinant	Dickson & Robinson	Lemon yellow	3½
Great Britain ..	Warnaar ..	Mauve	3
Hort. Fict	Warnaar ..	Salmon buff	3
Juliet	Burrell ..	Buff, suffused salmon	6
Melilla	Cory	Clear yellow	3
Malines	Dickson & Robinson	Yellow, suffused vermillion	4½
Mozart	Riding ..	Bright, deep crimson	4

Offenbach	Riding ..	Pure yellow	5
Reginald Cory...	Cheal ...	Crimson, tipped white	2½
Sulphurea	West	Sulphur yellow	4

DAFFODIL NOTES FROM NEW ZEALAND.

Judging at the Midland Daffodil Society's Show.—The sixteenth annual report of the Midland Daffodil Society has recently come to hand, and though the usual dinner and discussion on Daffodil matters did not take place in 1914, it provides interesting reading. The lists of the varieties shown in the various winning stands are always well conned, and enable us to make some comparison with our shows and form an idea as to how up to date we are out here.

The Midland Daffodil Society's exhibition deservedly occupies a leading position among spring shows, and its lead is largely followed by kindred societies in New Zealand and elsewhere. On this ground I feel constrained to refer to one matter disclosed by the report, which has caused me some surprise, and that is the number of stands which secure awards though not complying with the schedule. This feature first caught my attention when, in perusing the 1913 report, I noticed that Mme. de Graaff was shown in the first and second prize stands in Class 4 as a white trumpet (Division I.B), and also in the second and fourth prize stands in Class 5 as a bicolor trumpet (Division I.C).

In going through the 1914 report I note that S.T.H.W. (a new seedling, presumably) is shown in Class 22 as a triandrus hybrid (Division V.), and also in Class 25 as a Tazetta hybrid (Division VIII.), while in at least nine other

stands appear one or two varieties belonging to divisions other than those prescribed (as per list enclosed). These irregularities seem to occur more often in the open than in the amateur classes, and are apparently not dealt with by the judges, who I assume merely adjudicate on the comparative merits of the blooms as staged, and are tacitly acquiesced in by the exhibitors, as no protests are mentioned.

My object in writing is to enquire and ascertain for the benefit of Colonial shows whether the matter has been brought up and considered, and what, if any, remedies are suggested. I know from experience some of the difficulties the judges meet, also the disinclination of exhibitors (especially in a small community like ours, where they are all more or less acquainted) to win on a protest; but it seems hardly fair that exhibitors who are careful to comply strictly with the schedule should be prejudiced in this way. It seems to me that the personal element will usually deter exhibitors from bringing forward these irregularities by way of protest, and that therefore it should be the duty of some official to have them dealt with.

Horticultural Hall, Auckland, New Zealand.—The accompanying view is of the new Horticultural Hall belonging to the Auckland Horticultural Society, and used for the first time on the occasion of the Society's spring show on September 4 and 5 last. The building was erected and occupied as the Art Gallery in connection with the recent Auckland Exhibition, at the conclusion of which the Auckland Horticultural Society took advantage of the opportunity offered and purchased the hall, after having arranged with the City Council as to the ground rent. The situation in the Domain Reserve is one of the most beautiful round Auckland, commanding fine views of the harbour and north shore, and as the Council is maintaining and adding to the lawns, flower-beds, &c., which were laid out for the exhibition, the surroundings of the hall will be a great help to our shows. The building is roomy, convenient, and well lighted by day and night. Exhibitors at the spring show were well pleased with it, and as a great saving in rent, labour and other expenses is effected, as compared with the Town Hall, where the horticultural shows were previously held, the society is to be congratulated on its enterprise, being, as I believe, the first in the colony to acquire show premises of its own.

Auckland, New Zealand. A. E. GRINDROD.

THE EDITOR'S TABLE.

Fruits of *Benthamia fragifera*.—Mr. T. H. O. Pease, Skaigh, Okehampton, Devon, sends shoots of this beautiful shrub, which are bearing ripe fruits. These are about three-quarters of an inch in diameter, dull purplish red in colour, with a rough, wart-like exterior. It would be interesting to learn if this shrub fruits in other parts of the country. Mr. Pease writes: "I

send you some fruit of *Benthamia fragifera* grown here in a garden facing Dartmoor at a height of 900 feet above the sea. There has been much correspondence about the hardiness of *Choisya ternata* which makes me smile. There are large bushes here 7 feet or 8 feet high that get no protection beyond that afforded by surrounding shrubs, and I have not known them cut in the severest frosts."

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

INFORMATION ABOUT LILY POOL (S.).—Unless the plants can be accommodated in the pool itself, the true Water Lilies (*Nymphaeas*) would be quite useless to you. For these an assured depth and supply of water is essential. By arranging mounds of soil at intervals

elegant habit and very free. Either of these would be equally as good as that first named. An alternative plan would be to have a *Godetia* garden, arranging each bed with a different colour, using the double pink-flowered *Schaminii* for the star-shaped bed. In the event of your doing this, we would suggest that the four crescent-shaped beds be all edged with white *Alyssum*.

THE GREENHOUSE.

CYCLAMENS UNSATISFACTORY (J. H.).—Judging by the appearance of the specimen sent, your plants of *Cyclamen* have been kept in a too close and moisture-laden atmosphere. These plants need a free circulation of air around the corms, for which reason they are often stood on inverted pots in order to keep them clear of stagnant moisture. The watering, too, needs to be carefully done, especially when the flower-buds form. So if the crown is wetted, decay is very likely to set in. An excess of stimulants, too, may have the same effect. If the corm were very wet, it is quite possible that the sudden drop in the temperature would help towards the mischief.

FRUIT GARDEN.

TREATMENT OF VINES IN WINTER (Garden Lover).—No time should be lost in pruning the Vines. Delay may cause the wounds to bleed. Cut all the side shoots

THE NEW HORTICULTURAL HALL, AUCKLAND, NEW ZEALAND.

in the bottom of the pool this would be simple enough. The soil should be strong loam with manure, and each mound should contain about six bushels. On to these the plants should be sunk. In no other way will you get the water surface covered with leaves and flowers so well. For the side cavity many things could be named, *Gunnera*, *Swamp Lily*, *Ferns*, *hardy Orchids*, *Reeds*, *Grasses* and the like, though not all of these would spread to the water, and some would be too large for the width of the pool described. Assuming that the outer wall of the pool is quite water-tight, the mound planting suggested might be displaced by breaking into the inner wall of the pool low down to permit of inserting the rhizomes of the *Lilies* therein, so that they will be beneath the water and in touch with the soil provision at the sides at one and the same time. If this is possible, please write us again, with fuller particulars, to enable us to reply in detail.

ANNUALS FOR BEDS (West Lynne).—For the eight-pointed star bed employ a single plant of the Summer Cypress (*Kochia trichophylla*) in the centre, with either *Godetia* *Crimson King* or *Tagetes* *Legion of Honour* around—the last named has golden yellow flowers with a velvety maroon blotch on each petal—using the white *Alyssum maritimum* for the points of the star. For the four crescent-shaped beds we think you cannot do better than employ the large-flowered *Nemesias* in pink, yellow, orange, and scarlet, one colour to each bed. There are other varieties of *Godetia*, as *Lady Satin Rose* (rose pink), *Scarlet Queen*, *Ladybird* (white, crimson spotted) and the double pink-flowered *Schaminii*, the last named of

of this year's growth to within one bud of their base (leaving a few leaves on the shoots does not matter). Take off the loose bark from the surface of the Vines by rubbing with the hand. Some people scrape with a knife (do not do this), the object being to expose any embryo insects there may be hiding under the bark. Afterwards wash the Vines with an emulsion of soft soap and warm water, a quarter of a pound of soft soap to a gallon of water. An old carriage brush or one of a similar description is useful for the purpose. Be careful not to brush the buds at the base of the cut shoots. It is these buds which will produce the Grapes. After this is done, sling the Vines loosely to the trellis. Have the glass and woodwork of the vinery washed inside and out. Keep the vinery cool by admitting plenty of air day and night; 8° or 10° of frost will not hurt the Vines. If the border is inside and, as you say, cracking, give it a good soaking of manure-water from the cow or stable yard two or three times. If the border is outside, it will be wet enough, and you had better cover it with fresh leaves to the depth of 7 inches and cover the leaves with a thin layer of straw, cording it down to keep the leaves from blowing about. If the bases of the Vines are exposed where they enter through the wall, protect from frost with haybands or straw. Write us later; we shall be pleased to help you further.

HOW TO PRUNE A NEWLY PLANTED YOUNG PEACH TREE (R. J. F.).—The answer is, prune back to within a foot of the base of new shoots. By doing this you will find in the spring that buds will

form shoots from base to summit of what there is left of these shoots, whereas, if these shoots were not thus severely pruned, new shoots next year would only be formed at the apices of the shoots, leaving their base bare of shoots and fruit for all time afterwards.

TREES AND SHRUBS.

WHEN TO PRUNE CARPENTERIA CALIFORNICA (*Penwarrne*).—You cannot do better than prune your *Carpenteria* about the first week in March. Prune just sufficiently to shape the bush, but do not cut it back unduly hard. Your plant of *Clematis* can be pruned any time after the end of January and before the new shoots appear. It can be pruned back to within two or three buds of the base of last season's wood, and some branches can be removed outright if you wish.

PLANTS FOR HEDGE (*Enquirer*).—A good Thorn hedge will answer your purpose in the described position better than the Myrobalan or Cherry Plum. To give entirely satisfactory results the Cherry Plum should have a fairly open position, and even then it scarcely forms such a strong hedge as the Hawthorn. It, however, grows more rapidly in the early stages, as the Thorn is rather slow-growing for a few years. Be careful to work the ground well before planting. We do not know where a good Myrobalan hedge is to be seen.

FIR WITH SILVERY FOLIAGE (*Mrs. J. S. T.*).—There are several Firs which bear glaucous or silvery foliage. Perhaps the best is *Abies nobilis glauca*; then there are *A. concolor* var. *argentea* Walleyi, *A. lasiocarpa* caerulea and *A. magnifica*, all of which bear silvery leaves. Apart from the true Firs, perhaps the best of all conifers as regards silvery leaves are *Picea pungens glauca* and *Cedrus atlantica glauca*. These two are even better than *Abies nobilis glauca*. The *Abies* may be obtained up to 4 feet or 5 feet in height, the *Picea* up to 3 feet or 4 feet and the *Cedrus* up to 8 feet; but as a rule small plants become established more quickly than large ones.

KITCHEN GARDEN.

INSECTS ON BRUSSELS SPROUTS ROOTS (*A. H.*).—The club root disease of Turnips and Cabbages is not caused by the small white insects to which you refer, but by a minute and altogether microscopic fungus which is called *Plasmodiophora brassicae*. The presence of the small white insects, however, suggests that you have not limed your soil lately, and nothing but a dressing of quicklime, applied in autumn, will be likely to cure the trouble from which your plants are suffering.

BRUSSELS SPROUTS A FAILURE (*Redcliffe*).—It is seldom one hears of a failure in the growth of this valuable vegetable, and the failure in this instance, we think, is due to an attack of what is termed "clubbing" at the roots. This disease is caused by a minute fungus (*Plasmodiophora brassicae*), which confines its attack to plants of Brassica and other cruciferous plants, such as Turnips, Swedes and Radishes. The fungus may remain dormant in the ground for years, and only become active when plants of the Cabbage tribe are planted. This fungus causes a swelling or deformity at the base of the stem, which cripples the root power of the plants and causes failure. The best remedy for the destruction of the fungus has been found to be quicklime, applied at the rate of three bushels to the rod or perch, and dug in not deeper than 7 inches. The plants should be destroyed by burning, as there is danger of communicating the disease to other parts of the garden if allowed to decay and applied as manure. The land affected should be deeply trenched and liberally manured in winter, applying the lime as above in spring, and crop with Potatoes. The precaution must also be taken of not planting any plants of the Cabbage tribe in the affected soil for at least two years.

MISCELLANEOUS.

MANURE FOR SOIL (*A Beginner*).—We think ten loads of manure would not be too much for a first treatment of your land, and that it would be well to give a dressing of powdered chalk, to be dusted on while digging as well, otherwise your treatment should give good results.

OPENING FOR YOUNG GARDENER (*E. M.*).—Believing that there are as good fish in the sea as have ever been caught, we also believe that the chances for a young gardener are as good as ever they were, while the opportunities for acquiring knowledge are to-day a hundred-fold greater than forty years ago. Before we can advise you, however, it would be necessary to know what experience you have had, and particularly what your inclinations are. Gardening in its broadest sense is made up of many branches, the seed and bulb trade, bulb farming, landscape gardening, fruit culture, alpine and hardy plant gardening, market gardening, vegetable and flower and scientific gardening being some of them. Then, of course, a private gardener requires a totally different training to the commercial gardener, though the principles of gardening should be well grounded in each. Let us hear from you again and tell us your bent, when we will advise you to the best of our ability.

PLANT FOR SCREEN (*R. R.*).—The simpler way to hide the pump, if by reason of environment it is also practicable, would be to plant an enclosing fence of an erect-growing conifer, e.g., *Cupressus lawsoniana erecta* viridis, or even Oval-leaved Privet, outside of which Apples or Plums could be arranged at will. None of the fruit trees or climbers named in your letter would obscure the pump very much from view in winter-time, though the arrangement suggested would do it effectually, and provide fruit of a useful kind in addition. An alternative to the first would be to embower the pump with an iron arch and plant the most evergreen Roses—*wichurianas*—thereon, with the fruit trees around. This would take up the least room, with "honours easy" in respect to the useful and the beautiful. We are afraid we cannot recommend a fruit immune from the "attacks of birds," as these vary considerably with localities. The contents of the tank should be of much value in the vegetable garden.

NAME OF PLANT.—*M. A. C.*—White Beam Tree (*Pyrus Aria*), best propagated by means of seeds.

NAMES OF FRUIT.—*E. L. B.*—1, Beurré d'Anjou; 2, Josephine de Malines.

OBITUARY.

MRS. THOMAS STEVENSON.

THE many friends of Mr. Thomas Stevenson, the well-known Sweet Pea enthusiast of Woburn Place Gardens, Addlestone, Surrey, will learn with the deepest sorrow of the death of Mrs. Stevenson, which occurred, after a short illness, on Christmas Day. The deceased was a quiet, unassuming woman, and took the keenest interest in her husband's work, more especially that section of it devoted to Sweet Peas and Chrysanthemums. All who know Mr. Stevenson will, we are sure, join us in tendering to him our deepest sympathy in the sad and irreparable loss that he has sustained.

TRADE NOTES.

BOOTS FOR COUNTRY WEAR.

THOSE who live in the country know how essential it is to secure and wear good boots, especially during wet and cold weather, and they also know how difficult it is to procure locally just the quality and style that are required. We are reminded of this by the receipt of a splendidly illustrated catalogue of "Fife" footwear from Mr. A. T. Hogg, Strathmiglo, Fife, N.B. Mr. Hogg has for many years made a speciality of boots for country wear, both for ladies and gentlemen, and we strongly advise our readers to write to him for a free copy of this catalogue. All the boots and shoes mentioned and illustrated in its pages are thoroughly reliable, and made in sizes and styles to fit every foot, while the prices are as low as possible considering the quality.

A BEAUTIFUL SEED CATALOGUE.

THE superb catalogue of vegetable and flower seeds for 1915 that we have just received from Messrs. E. Webb and Sons of Wordsley, Stourbridge, is of a particularly interesting character. As usual, it is thoroughly well illustrated, and the particulars of the many kinds of seeds the firm offers are set forth in an instructive and interesting manner. Messrs. Webb have for many years been in the front rank of seedsmen who make a speciality of high-class vegetables; and as there is likely to be a larger demand than usual for vegetables this year, we advise all our readers to write to them for a copy of this catalogue, which will be sent gratis and post free if THE GARDEN is mentioned. Several fine novelties of vegetables and flowers are offered in its pages, and it is a book well worth keeping for future reference.

"BEES' GUARANTEED SEEDS."

THIS is the title of the neat and well-compiled seed catalogue for 1915 just published by Messrs. Bees, Limited, Mill Street, Liverpool. Within its pages will be found particulars of all good vegetables and flowers, many of which are well illustrated in colours. In addition there are many half-tone illustrations, which convey to the reader a good idea of results that have been obtained from the firm's seeds. Messrs. Bees state that the whole of the seeds offered in this catalogue have been obtained from British, Colonial, French and American growers and merchants. They will be pleased to send a copy post free to any reader who cares to write for it.

CATALOGUES RECEIVED.

Messrs. Thompson and Morgan, Ipswich: Herbaceous and Alpine Plants.
Messrs. Sutton and Sons, Reading: Seeds.
Messrs. W. Atlee Burpee and Co., Burpee Buildings, Philadelphia, U.S.A.: Seeds.
Messrs. Bees, Limited, Mill Street, Liverpool: Seeds.
Messrs. E. Webb and Sons, Wordsley, Stourbridge: Seeds.
Messrs. Cooper, Taber and Co., 90 and 92, Southwark Street, London, S.E.: Seeds (wholesale only).
Messrs. J. Peed and Sons, West Norwood: Seeds.
Messrs. J. Stormonth and Sons, Kirkbride, Carlisle: Seeds.
Messrs. Dobbie and Co., Edinburgh: Seeds.
Messrs. Lemoine and Sons, Rue du Montet, Nancy: Gladioli.
Messrs. Stuart Low and Co., Bush Hill Park, Middlesex: Carnations.
Mr. W. J. Unwin, Histon, Cambs: Sweet Peas and Other Flower and Vegetable Seeds.

* * * The Yearly Subscription to THE GARDEN is: Inland, 6s. 6d.; Foreign, 8s. 9d.

To Secretaries, Horticultural Societies. Schedule covers, printed three colours on thick art paper, can be had gratis, with necessary printing done free. For particulars apply

175c, Mill St.,
LIVERPOOL.

Your Seeds need not cost you more. If you are wise and buy Bees' Guaranteed Seeds they will actually cost less than in 1914. Is it possible?

Yes. It is more than possible, it is absolute fact. The price of Bees seed, especially of garden peas, has actually been reduced in spite of the war.

And you have the additional satisfaction, if you buy from Bees, of knowing that the seed is

British, Colonial, French or American.

You are given this assurance in a special message from the "Manager Bee."

As to the quality you simply cannot get better seed. Bees Ltd. make no claim that their seed is "the best" in the sense that all other seed is inferior. But they do affirm that it is equal to the best in the land, more than that no one can hope for. And this assurance is given under a cash warranty or guarantee. You are invited to test Bees' Seeds, and if they should not prove satisfactory Bees Ltd. guarantee to return your cash in full.

Test one of these Sweet Pea Collections on these terms.

7214. Bees' 'Mersey' Collection of Sweet Peas, 1/6.

12 Up-to-Date Varieties. 10 seeds of each.

	1d.	3d.
7226 Afterglow, violet blue ...	4	20
7251 Dobbies' Cream, primrose ...	5	25
7261 Sunproof Crimson, ...	5	25
7266 Prince George, lilac rose ...	3	15
7272 Mrs. Heslington, lavender ...	5	25
7284 King Manoel, maroon ...	3	15
7302 Thos. Stevenson, orange ...	5	25
7311 Elfrida Pearson, pale pink ...	5	25
7312 Hercules, deep pink ...	5	25
7318 Barbara, salmon... ..	4	20
7337 America Spencer, red white ...	5	25
7343 King White, grand ...	3	15

For Smaller Gardens.

7215. Bees' 'Liverpool' Collection, 6d.

10 Seeds each in separate packets.

	1d.	3d.
7263 Maud Holmes, crimson ...	5	25
7295 Queen of Norway, mauve ...	5	25
7303 Edna Unwin, orange ...	5	25
7313 Countess Spencer, pink ...	10	50
7321 Earl Spencer, salmon ...	5	25
7341 Etta Dyke, pure white ...	10	50

For Larger Gardens.

7216. Bees' 'Lancashire' Collection.

This contains the 18 varieties enumerated above in the Mersey and Liverpool Collections, 10 seeds of each, and is first-rate value at

2/- TWO SHILLINGS. 2/-

Any variety can be had separately in 1d. or 3d. packets containing the quantity of seeds noted alongside the description.

Mixed Sweet Peas.

7375. Bees' Fairy or Spencer Mixture.

9d. oz., 100 seeds, 3d., 20 seeds, 1d.

7377 Grandiflora Xd., 3d. oz., 60 seeds, 1d.
7379 Cupid S. Peas Xd., 3d. ½-oz., 50 seeds, 1d.

Send your order Now. Add 1d. for postage on orders under 2/6 value, and ask for Catalogue. It contains Natural Colour Illustrations of Sweet Peas and other flowers. Altogether there are 12 pages of colour. Order or write to-day. NOW.

"Lest you Forget."

LIVERPOOL.

THE GARDEN.

No. 2252.—VOL. LXXIX.

JANUARY 16, 1915.

NOTES OF THE WEEK.

Kew and the War.—According to the current issue of the *Kew Bulletin*, the number of men from the Royal Botanic Gardens now serving with His Majesty's Army is sixty-six.

The Chinese Witch Hazel.—For six weeks—from the middle of December to the end of January—should the weather prove moderately mild, the bright golden blossoms of the Chinese Witch-Hazel (*Hamamelis mollis*) make it one of the most attractive plants imaginable, for not only is every twig laden with showy flowers, but they are also fragrant with a pleasant Primrose-like perfume. Strange to say, although this shrub was introduced as long ago as 1879, it is only during the last fifteen years that it has come to be known, and even now, although it is the best of the Witch Hazels, it is by no means common. When planted in rather light, loamy soil containing a little leaf-mould or peat, it grows well and soon forms a shapely bush 3 feet or 4 feet high; eventually it will probably grow three times that height.

A Good Greenhouse Acacia.—Among the Acacias of dwarf habit suitable for growing in pots, few can surpass *A. platyptera*. This forms a neat, erect bush from 18 inches to 3 feet in height, which from November until well into February produces its golden blossoms in abundance. These are globular, and are borne in clusters of usually five to eight. In mature plants true leaves are seldom present, their functions being carried out by the flattened leaf-like stems. To keep the plants dwarf and shapely, the growths are cut back fairly hard after the flowers have faded. In common with other members of the family, this Acacia appreciates soil that contains a quantity of peat and sand, with good loam forming the bulk.

The True Chinese Primula.—In House No. 4 at Kew just now there are some flowering plants of *Primula sinensis* which are the direct descendants of plants raised from seeds collected in China by Mr. E. H. Wilson. These have pale mauve blossoms of stellate shape, the whorls of flowers being borne in tiers as in the stellate garden forms of *Primula sinensis*. It has been generally assumed that our garden varieties of this *Primula* have all originated from the wild plant, but we believe some authorities are now disposed to doubt the correctness of this. It

rather seems as though the so-called wild Chinese *Primulas* that have reached this country previously have been cultivated varieties in China.

Our Sub-Editor on Active Service.—We think the following letter from our Sub-Editor, Mr. H. Cowley, who is now serving with the British Expeditionary Force in France, will be of interest to readers: "Since our arrival in France we have been camped under canvas in a dreadful quagmire,

thatched cottages, but the wilding that has given me the greatest pleasure is Traveller's Joy, here, as in our Surrey lanes, seen rambling over farm buildings and invariably marking the approach to a village, often a most welcome sight after a march over open country."

A Beautiful Hardy Annual.—The illustration on this page represents one of the most charming of all hardy annuals, and one that ought to be found in every garden. It is usually listed in seed catalogues as *Leptosiphon densiflorus hybridus* or *Leptosiphon French hybrids*. Seed sown in the open early in April quickly germinates, and the seedlings soon make neat tufts of plumose greenery, whence the dainty little flowers spring in abundance. These are of various art shades, and never fail to elicit praise from all who see them. As its average height is 4 inches, it is ideal for carpeting beds of taller plants, for edgings to pathways, and for nooks in the rock garden. It will thrive in any good garden soil, but should be given a sunny position, as the flowers do not open well in shade. We refer to it now so that it may be included in the seed order, as we do not know of any other dwarf hardy annual capable of giving so much pleasure as this.

LEPTOSIPHON DENSIFLORUS HYBRIDUS, A BEAUTIFUL DWARF HARDY ANNUAL.

A Useful Old-Fashioned Greenhouse Plant.—Those who remember the time when hard-wooded greenhouse plants were well cultivated and highly appreciated will know how valuable *Chorizanthe ilicifolia* is for the conservatory during the early days of the year. It may still be found in a number of good gardens, but deserves to be much more widely known. It makes a neat bush, and from January onwards until well into the spring is freely bespangled with its small, Pea-shaped blossoms, which have a vivid orange standard and purple wings. These contrast charm-

ingly with the deep green, Holly-like foliage. This and other members of the family need good loam, peat and sharp sand as a rooting medium, and at repotting, which is best done just as new growth is being made, this must be rammed quite firm. To keep the plants bushy they may be cut hard back after flowering. In the month of July the pots should be plunged in ashes outside, so as to thoroughly open the new wood before the winter.

but, despite most depressing surroundings, we have kept merry and bright. Now we are billeted in a small village, very comfortable, well fed and well worked. There is one side of the life that most fellows miss, but never escapes my observation—I mean the trees and other vegetation. The Venetian Sumach looks fine, and the Norfolk Island Pine—looked upon as tender at home—stands the severe weather here with impunity. I have seen Irises growing freely on the roofs of

form shoots from base to summit of what there is left of these shoots, whereas, if these shoots were not thus severely pruned, new shoots next year would only be formed at the apices of the shoots, leaving their base bare of shoots and fruit for all time afterwards.

TREES AND SHRUBS.

WHEN TO PRUNE CARPENTERIA CALIFORNICA (*Penwarrne*).—You cannot do better than prune your *Carpenteria* about the first week in March. Prune just sufficiently to shape the bush, but do not cut it back unduly hard. Your plant of *Clematis* can be pruned any time after the end of January and before the new shoots appear. It can be pruned back to within two or three buds of the base of last season's wood, and some branches can be removed outright if you wish.

PLANTS FOR HEDGE (*Enquirer*).—A good Thorn hedge will answer your purpose in the described position better than the Myrobalan or Cherry Plum. To give entirely satisfactory results the Cherry Plum should have a fairly open position, and even then it scarcely forms such a strong hedge as the Hawthorn. It, however, grows more rapidly in the early stages, as the Thorn is rather slow-growing for a few years. Be careful to work the ground well before planting. We do not know where a good Myrobalan hedge is to be seen.

FIR WITH SILVERY FOLIAGE (*Mrs. J. S. T.*).—There are several Firs which bear glaucous or silvery foliage. Perhaps the best is *Abies nobilis glauca*; then there are *A. concolor* var. *argentea* Wallezli, *A. lasiocarpa cærulescens* and *A. magnifica*, all of which bear silvery leaves. Apart from the true Firs, perhaps the best of all conifers as regards silvery leaves are *Picea pungens glauca* and *Cedrus atlantica glauca*. These two are even better than *Abies nobilis glauca*. The *Abies* may be obtained up to 4 feet or 5 feet in height, the *Picea* up to 3 feet or 4 feet and the *Cedrus* up to 8 feet; but as a rule small plants become established more quickly than large ones.

KITCHEN GARDEN.

INSECTS ON BRUSSELS SPROUTS ROOTS (*A. H.*).—The club root disease of Turnips and Cabbages is not caused by the small white insects to which you refer, but by a minute and altogether microscopic fungus which is called *Plasmodiophora brassicæ*. The presence of the small white insects, however, suggests that you have not limed your soil lately, and nothing but a dressing of quicklime, applied in autumn, will be likely to cure the trouble from which your plants are suffering.

BRUSSELS SPROUTS A FAILURE (*Redcliffe*).—It is seldom one hears of a failure in the growth of this valuable vegetable, and the failure in this instance, we think, is due to an attack of what is termed "clubbing" at the roots. This disease is caused by a minute fungus (*Plasmodiophora brassicæ*), which confines its attack to plants of *Brassica* and other cruciferous plants, such as Turnips, Swedes and Radishes. The fungus may remain dormant in the ground for years, and only become active when plants of the Cabbage tribe are planted. This fungus causes a swelling or deformity at the base of the stem, which cripples the root power of the plants and causes failure. The best remedy for the destruction of the fungus has been found to be quicklime, applied at the rate of three bushels to the rod or perch, and dug in not deeper than 7 inches. The plants should be destroyed by burning, as there is danger of communicating the disease to other parts of the garden if allowed to decay and applied as manure. The land affected should be deeply trenched and liberally manured in winter, applying the lime as above in spring, and crop with Potatoes. The precaution must also be taken of not planting any plants of the Cabbage tribe in the affected soil for at least two years.

MISCELLANEOUS.

MANURE FOR SOIL (*A Beginner*).—We think ten loads of manure would not be too much for a first treatment of your land, and that it would be well to give a dressing of powdered chalk, to be dusted on while digging as well, otherwise your treatment should give good results.

OPENING FOR YOUNG GARDENER (*E. M.*).—Believing that there are as good fish in the sea as have ever been caught, we also believe that the chances for a young gardener are as good as ever they were, while the opportunities for acquiring knowledge are to-day a hundred-fold greater than forty years ago. Before we can advise you, however, it would be necessary to know what experience you have had, and particularly what your inclinations are. Gardening in its broadest sense is made up of many branches, the seed and bulb trade, bulb farming, landscape gardening, fruit culture, alpine and hardy plant gardening, market gardening, vegetable and flower and scientific gardening being some of them. Then, of course, a private gardener requires a totally different training to the commercial gardener, though the principles of gardening should be well grounded in each. Let us hear from you again and tell us your bent, when we will advise you to the best of our ability.

PLANT FOR SCREEN (*R. R.*).—The simpler way to hide the pump, if by reason of environment it is also practicable, would be to plant an enclosing fence of an erect-growing conifer, e.g., *Cupressus lawsoniana erecta* viridis, or even Oval-leaved Privet, outside of which Apples or Plums could be arranged at will. None of the fruit trees or climbers named in your letter would obscure the pump very much from view in winter-time, though the arrangement suggested would do it effectually, and provide fruit of a useful kind in addition. An alternative to the first would be to embower the pump with an iron arch and plant the most evergreen Roses—*wichuriana*—thereon, with the fruit trees around. This would take up the least room, with "honours easy" in respect to the useful and the beautiful. We are afraid we cannot recommend a fruit immune from the "attacks of birds," as these vary considerably with localities. The contents of the tank should be of much value in the vegetable garden.

NAME OF PLANT.—*M. A. C.*—White Beam Tree (*Pyrus Aria*), best propagated by means of seeds.

NAMES OF FRUIT.—*E. L. B.*—1, Beurré d'Anjou; 2, Josephine de Malines.

OBITUARY.

MRS. THOMAS STEVENSON.

THE many friends of Mr. Thomas Stevenson, the well-known Sweet Pea enthusiast of Woburn Place Gardens, Addlestone, Surrey, will learn with the deepest sorrow of the death of Mrs. Stevenson, which occurred, after a short illness, on Christmas Day. The deceased was a quiet, unassuming woman, and took the keenest interest in her husband's work, more especially that section of it devoted to Sweet Peas and Chrysanthemums. All who know Mr. Stevenson will, we are sure, join us in tendering to him our deepest sympathy in the sad and irreparable loss that he has sustained.

TRADE NOTES.

BOOTS FOR COUNTRY WEAR.

THOSE who live in the country know how essential it is to secure and wear good boots, especially during wet and cold weather, and they also know how difficult it is to procure locally just the quality and style that are required. We are reminded of this by the receipt of a splendidly illustrated catalogue of "Fife" footwear from Mr. A. T. Hogg, Strathmiglo, Fife, N.B. Mr. Hogg has for many years made a speciality of boots for country wear, both for ladies and gentlemen, and we strongly advise our readers to write to him for a free copy of this catalogue. All the boots and shoes mentioned and illustrated in its pages are thoroughly reliable, and made in sizes and styles to fit every foot, while the prices are as low as possible considering the quality.

A BEAUTIFUL SEED CATALOGUE.

THE superb catalogue of vegetable and flower seeds for 1915 that we have just received from Messrs. E. Webb and Sons of Wordsley, Stourbridge, is of a particularly interesting character. As usual, it is thoroughly well illustrated, and the particulars of the many kinds of seeds the firm offers are set forth in an instructive and interesting manner. Messrs. Webb have for many years been in the front rank of seedsmen who make a speciality of high-class vegetables; and as there is likely to be a larger demand than usual for vegetables this year, we advise all our readers to write to them for a copy of this catalogue, which will be sent gratis and post free if THE GARDEN is mentioned. Several fine novelties of vegetables and flowers are offered in its pages, and it is a book well worth keeping for future reference.

"BEES' GUARANTEED SEEDS."

THIS is the title of the neat and well-compiled seed catalogue for 1915 just published by Messrs. Bees, Limited, Mill Street, Liverpool. Within its pages will be found particulars of all good vegetables and flowers, many of which are well illustrated in colours. In addition there are many half-tone illustrations, which convey to the reader a good idea of results that have been obtained from the firm's seeds. Messrs. Bees state that the whole of the seeds offered in this catalogue have been obtained from British, Colonial, French and American growers and merchants. They will be pleased to send a copy post free to any reader who cares to write for it.

CATALOGUES RECEIVED.

Messrs. Thompson and Morgan, Ipswich: Herbaceous and Alpine Plants.
Messrs. Sutton and Sons, Reading: Seeds.
Messrs. W. Atlee Burpee and Co., Burpee Buildings, Philadelphia, U.S.A.: Seeds.
Messrs. Bees, Limited, Mill Street, Liverpool: Seeds.
Messrs. E. Webb and Sons, Wordsley, Stourbridge: Seeds.
Messrs. Cooper, Taber and Co., 90 and 92, Southwark Street, London, S.E.: Seeds (wholesale only).
Messrs. J. Peed and Sons, West Norwood: Seeds.
Messrs. J. Stormonth and Sons, Kirkbride, Carlisle: Seeds.
Messrs. Dobbie and Co., Edinburgh: Seeds.
Messrs. Lemoine and Sons, Rue du Montet, Nancy: Gladioli.
Messrs. Stuart Low and Co., Bush Hill Park, Middlesex: Carnations.
Mr. W. J. Unwin, Histon, Cambs: Sweet Peas and Other Flower and Vegetable Seeds.

* * * The Yearly Subscription to THE GARDEN is: Inland, 6s. 6d.; Foreign, 8s. 9d.

To Secretaries, Horticultural Societies. Schedule covers, printed three colours on thick art paper, can be had gratis, with necessary printing done free. For particulars apply

175C, Mill St.,
LIVERPOOL.

Your Seeds need not cost you more. If you are wise and buy Bees' Guaranteed Seeds they will actually cost less than in 1914. Is it possible?

Yes. It is more than possible, it is absolute fact. The price of Bees seed, especially of garden peas, has actually been reduced in spite of the war.

And you have the additional satisfaction, if you buy from Bees, of knowing that the seed is

British, Colonial, French or American.

You are given this assurance in a special message from the "Manager Bee."

As to the quality you simply cannot get better seed. Bees Ltd. make no claim that their seed is "the best" in the sense that all other seed is inferior. But they do affirm that it is equal to the best in the land, more than that no one can hope for. And this assurance is given under a cash warranty or guarantee. You are invited to test Bees' Seeds, and if they should not prove satisfactory Bees Ltd. guarantee to return your cash in full.

Test one of these Sweet Pea Collections on these terms.

7214. Bees' 'Mersey' Collection of Sweet Peas, 1/6.

12 Up-to-Date Varieties. 10 seeds of each.

THE GARDEN.

No. 2252.—VOL. LXXIX.

JANUARY 16, 1915.

NOTES OF THE WEEK.

Kew and the War.—According to the current issue of the *Kew Bulletin*, the number of men from the Royal Botanic Gardens now serving with His Majesty's Army is sixty-six.

The Chinese Witch Hazel.—For six weeks—from the middle of December to the end of January—should the weather prove moderately mild, the bright golden blossoms of the Chinese Witch Hazel (*Hamamelis mollis*) make it one of the most attractive plants imaginable, for not only is every twig laden with showy flowers, but they are also fragrant with a pleasant Primrose-like perfume. Strange to say, although this shrub was introduced as long ago as 1879, it is only during the last fifteen years that it has come to be known, and even now, although it is the best of the Witch Hazels, it is by no means common. When planted in rather light, loamy soil containing a little leaf-mould or peat, it grows well and soon forms a shapely bush 3 feet or 4 feet high; eventually it will probably grow three times that height.

A Good Greenhouse Acacia.—Among the Acacias of dwarf habit suitable for growing in pots, few can surpass *A. platyptera*. This forms a neat, erect bush from 18 inches to 3 feet in height, which from November until well into February produces its golden blossoms in abundance. These are globular, and are borne in clusters of usually five to eight. In mature plants true leaves are seldom present, their functions being carried out by the flattened leaf-like stems. To keep the plants dwarf and shapely, the growths are cut back fairly hard after the flowers have faded. In common with other members of the family, this Acacia appreciates soil that contains a quantity of peat and sand, with good loam forming the bulk.

The True Chinese Primula.—In House No. 4 at Kew just now there are some flowering plants of *Primula sinensis* which are the direct descendants of plants raised from seeds collected in China by Mr. E. H. Wilson. These have pale mauve blossoms of stellate shape, the whorls of flowers being borne in tiers as in the stellate garden forms of *Primula sinensis*. It has been generally assumed that our garden varieties of this *Primula* have all originated from the wild plant, but we believe some authorities are now disposed to doubt the correctness of this. It

rather seems as though the so-called wild Chinese *Primulas* that have reached this country previously have been cultivated varieties in China.

Our Sub-Editor on Active Service.—We think the following letter from our Sub-Editor, Mr. H. Cowley, who is now serving with the British Expeditionary Force in France, will be of interest to readers: "Since our arrival in France we have been camped under canvas in a dreadful quagmire,

thatched cottages, but the wilding that has given me the greatest pleasure is Traveller's Joy, here, as in our Surrey lanes, seen rambling over farm buildings and invariably marking the approach to a village, often a most welcome sight after a march over open country."

A Beautiful Hardy Annual.—The illustration on this page represents one of the most charming of all hardy annuals, and one that ought to be found in every garden. It is usually listed in seed catalogues as *Leptosiphon densiflorus hybridus* or *Leptosiphon French hybrids*. Seed sown in the open early in April quickly germinates, and the seedlings soon make neat tufts of plumose greenery, whence the dainty little flowers spring in abundance. These are of various art shades, and never fail to elicit praise from all who see them. As its average height is 4 inches, it is ideal for carpeting beds of taller plants, for edgings to pathways, and for nooks in the rock garden. It will thrive in any good garden soil, but should be given a sunny position, as the flowers do not open well in shade. We refer to it now so that it may be included in the seed order, as we do not know of any other dwarf hardy annual capable of giving so much pleasure as this.

A Useful Old-Fashioned Greenhouse Plant.—Those who remember the time when hard-wooded greenhouse plants were well cultivated and highly appreciated will know how valuable *Chorizema ilicifolium* is for the conservatory during the early days of the year. It may still be found in a number of good gardens, but deserves to be much more widely known. It makes a neat bush, and from January onwards until well into the spring is freely bespangled with its small, Pea-shaped blossoms, which have a vivid orange standard and purple wings. These contrast charm-

LEPTOSIPHON DENSIFLORUS HYBRIDUS, A BEAUTIFUL DWARF HARDY ANNUAL.

but, despite most depressing surroundings, we have kept merry and bright. Now we are billeted in a small village, very comfortable, well fed and well worked. There is one side of the life that most fellows miss, but never escapes my observation—I mean the trees and other vegetation. The Venetian Sumach looks fine, and the Norfolk Island Pine—looked upon as tender at home—stands the severe weather here with impunity. I have seen *Iris*s growing freely on the roofs of

ing with the deep green, Holly-like foliage. This and other members of the family need good loam, peat and sharp sand as a rooting medium, and at repotting, which is best done just as new growth is being made, this must be rammed quite firm. To keep the plants bushy they may be cut hard back after flowering. In the month of July the pots should be plunged in ashes outside, so as to thoroughly ripen the new wood before the winter.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Journal of the Royal Horticultural Society.—Though agreeing in the main with Mr. Engleheart's criticisms of this publication in last week's issue, page 14, and sharing in his objection to the amount of American material that the Editor has recently seen fit to incorporate in it, my complaint is more directed against the amount of purely scientific writing and its disproportionate relation to the treatment of everyday practical subjects. To one of the savants who desires to add to his store of knowledge by acquiring a better acquaintance with "The Plant in Relation to its Biological Environment," there must be at least a hundred Fellows who will eagerly devour, and gain profitable instruction from, the most practical and readable little article by Mr. H. G. Mount on the treatment of early Roses in pots. In my opinion Mr. Mount's four pages are worth more to the ordinary Fellow than the whole of the rest of the contents of this number of the Journal put together. The more of this sort of thing that Mr. Chittenden can give his readers the better, and the less likely will they be to throw the Journal aside almost as soon as it is opened, as is now very frequently the case.—F. HERBERT CHAPMAN.

Shows, Schedules and Judges.—After each show season one looks back with an increasing conviction that some reform is needed in the matter of shows, schedules and judging. We have a very large number of shows crowded into two or three months of the summer, the dates of some of which are fixed without regard to clashing, which in many cases might well be avoided. Of recent years it is becoming very apparent that show committees look upon trade exhibitors as their legitimate prey, and appear to have got the idea that the trade cannot exist without their show. They do not consider that without the trade their show would be very tame indeed; neither is the amount of stuff, the time, the work and the expense taken into account. True, there are a few which offer fair inducements in the way of prize money; there are more which offer a small amount for a big display, which does not even cover the cost of transit; while many, again, offer medals (which sometimes consist of the cards only). They give little or no assistance to enable the exhibitor from a distance to get "fixed up," give no help in finding suitable accommodation for a stranger, or to get away comfortably after the close. How often does the trade exhibitor lose his connection for home by having to wait for a conveyance! In fact, by many societies the trade exhibitor is treated unfairly and unjustly, and if at some time he consults his own pocket and becomes an absentee, perhaps a lesson will be taught. It must be in these days of keen competition for shows, the show

unable to interpret them. In Sweet Pea classes a great laxity as to number is often allowed, while in hardy flowers not one schedule in fifty stipulates that they shall be outdoor grown, and frequently an exhibit—poor in other respects—with one or two bunches of indoor-grown flowers (and here Liliiums, such as longiflorum, seldom grown outside, generally play a part), takes the honours, while an exhibit staged according to the spirit of the schedule is passed over; and we have seen some glaring examples of this. As to judges, how often it is apparent that these are selected from the position they hold without regard to their capability to fairly judge the

A FLOWERING SPRAY OF THE SOUTHERN HEATH
(ERICA AUSTRALIS).

classes assigned to them. It does not follow that an expert fruit-grower is an expert florist, or vice versa. Nor does it follow that a man holds his position always because of his expert knowledge and experience of either; and it is essential, nay, it is but justice, that a judge should be selected who knows, and has practical experience of, the classes he has to judge. Much dissatisfaction would then be saved. Schedules are now being prepared for another "round." Is it too much to ask that these points may receive consideration?—EXHIBITOR. [As this subject is of special interest just now, we shall be glad to have the opinions of others.—Ed.]

The Southern Heath (Erica australis).—

The accompanying photograph, which was taken on April 1 of last year, depicts a spray of the beautiful Southern Heath. With us in a rather sheltered Surrey garden the plants are in full beauty during April and early May. I remember early last year that Mr. T. Wilson, writing from Glamis, described *E. australis* as "generally in flower in the month of June." This is probably accounted for by a cooler soil and late locality. The Southern Heath has purplish red flowers, richer and rather brighter in colour than those of the Mediterranean Heath. From this species the subject of the illustration is also readily distinguished by its open, looser habit of growth. Growing from 3 feet to 5 feet or more in height, *E. australis* is a native of Portugal. It may be described as just on the border and of hardiness, for while the plants have come through the last two or three winters unharmed, we always insert a pot of cuttings of this species in company with *E. lusitanica* (codonodes) and *E. Veitchii*, which with us are the tenderest Tree Heaths. Another species which differs here from Glamis in the season of flowering is the South European *E. multiflora*. My notes say August 12 to October 24; at Glamis it flowers in the New Year.—A SURREY GARDEN.

The Late W. B. Latham : An Appreciation.

It was with feelings of deep regret that the writer, reading THE GARDEN of January 2, became acquainted of the death of Mr. W. B. Latham. I feel also that many gardeners and amateurs, throughout the Midland Counties especially, would receive the news with an equally genuine sorrow. To the many horticulturists who at one time or another had the privilege of knowing Mr. Latham must come the feeling of a real personal loss. During the period of his curatorship of Edgbaston Botanic Gardens, hundreds of gardeners must have had the benefit of his wise counsel. He was in his happiest vein when among his beloved plants or at any meeting where plant-life was the premier subject. At such meetings he was always chairman, and all present would feel that a master of craft was taking the lead. His wide knowledge of plants and their culture he was ever ready and willing to impart to anyone. He always appealed to the young men to seize every opportunity of acquiring knowledge, and several, mainly through his help, have become famous. He was indeed a lover of Nature, of things beautiful, which, I think, played a prominent part in his successful life, and yet he was the most simple-hearted of men. If I remember rightly, on the occasion of his sixtieth birthday and as chairman of a gardeners' meeting he remarked that he had lived for sixty years, only to feel how little he knew, for gardening was never learnt. His passing away leaves one with the thought that gardening is the poorer for his loss; but his charm and geniality of manner, his kindly advice and greatness of heart, will, I am sure, be cherished by many of your readers to the memory of Mr. W. B. Latham.—W. HOLCOMB, Bearwood, Staffs.

then per-
borne in mind that
tion and an increasing number
tent is by no means
orders.

Funkia subcordata grandiflora.—If Mr. Comfort, whose note on this plant appears on page 2, issue January 2, will grow the above variety, he will have a pure white Funkia and a fragrant one too; in fact, the blossoms of this variety are almost as good as those of *Pancreatum fragrans*. With me this Plantain Lily succeeds admirably in our stiff soil. Is there such a variety as *F. subcordata alba odorata*?—E. M.

Mildew-Proof Roses.—I have read with much interest the various notes which have of late weekly appeared in *THE GARDEN* regarding mildew-proof Roses. I quite agree with what Mr. John W. Hicks says as to certain Roses being attacked by mildew in certain localities and immune in others. Last year I had practically no trouble with either mildew or green fly, and the reason for this is simply that early in the season I sprayed every plant weekly (though I have not a large collection, but have over a hundred varieties) with Calvert's Carbolic Soft Soap. This preventive I can, therefore, highly recommend to all rosarians who wish to have nice clean plants. Perhaps it may interest readers to know that on New Year's Day, when there was 12° of frost and both curling and skating were indulged in here, I cut some beautiful blooms, grown in the open, from the following dwarfs, viz., Caroline Testout, Earl of Warwick, Friedrichsruh, Victor Hugo and Comtesse Icy Hardegg.—J. D. LAWRIE, *Craigielea, Duns, N.B.*

Butcher's Broom and Other Plants.

—You often refer to the dioecious character of the Butcher's Broom and the necessity of having both male and female plants if a display of berries is desired. Nobody who has ever seen a good plant in fruit can forget it, but what is wanted to be known is where to get a female plant or berries to raise plants from. For over twenty years have I received the invariable reply from nurserymen who have been asked for female plants, "None in stock." I was, fortunately, able last month to obtain three fruiting plants, but that apparently exhausted the supply. Then, as regards the flowering of the Banksian Rose, so frequently asked about and a blossoming plant of which cannot be purchased. Why is it not possible to buy a plant which will flower, when a piece broken off an old flowering climber, started before modern nursery grafting came into fashion, will grow and bloom? Is it the fault of the grafting? One more reference—as to *Iris susiana* not flowering. Perhaps if growers never allowed any side shoots to start and forced the growth into one centre stem, they might be successful.—A. L. FORD.

Cuttings with "Heels."—While wishful to impart information on matters horticultural to those with but little experience, would it not be much more to the point if writers would be a little more explanatory in a concise manner? Take, for example, the two notes on the above subject on page 594, issue December 12, 1914, and page 2, January 2. Practical persons know quite well that cuttings with heels are in some cases a great advantage; in others the reverse. Both writers are not clear enough to the uninitiated as to what subjects should be handled on the heel principle or the reverse. In the case of soft-wooded plants,

cuttings succeed best when cut close below a joint, not midway. Geraniums will root when cut midway between two leaves, but generally the portion has to first decay up to the joint, when rooting then quickly takes place. In cases like *Alternantheras*, the necessity to cut to a joint is not so great. The propagation of conifers, Roses under glass, shrubs generally, Lavender, &c., all succeed better under the heel system than without, especially with Roses under glass and in the open. No plant that I know displays the advantage of adding a heel so much as a Laurel cutting. In a like manner *Aucubas* respond quickly under glass to root production from heels as opposed to midway severance.—S. [Mr. Jenkins will deal fully with this subject in our next issue.—ED.]

Ginkgo biloba or Maidenhair Tree.—The Japanese name of this curious tree is Ginkyo or Jeho, and the fruit is called Ginnan. To one who has known and loved the Ginkgo in many parts of Japan, it seems far easier and better to call it by that name than to trot out the whole twelve syllables of *Salisburia adiantifolia*, and I hope your correspondent "H. P.," whose note appears on page 2, issue January 2, will

LILIAM REGALE, OFTEN KNOWN AS L. MYRIOPHYLLUM. IT IS A COMPARATIVELY NEW SPECIES TO OUR GARDENS.

allow me to disagree with him when he calls Ginkgo "an awkward sounding word." The penultimate "g" should be spoken softly—more like "y." The fruit we call Persimmon comes from Japan, and there is called Kaki. In France the Persimmon is better known than in Britain, and I am told the French now call it Kaki. Why should we be afraid to call the Ginkgo by its original name? I would be glad to know what name the French give to it. The fruits, or rather cones, of the Ginkgo are more like Olives than Larch or Fir cones, and the Japanese often use them in a pickled form, just as we use Olives. They are, however, very inferior to Olives. The Ginkgo seems to be quite hardy in Perthshire, but the comparative severity of the winters hinders vigorous growth. In Japan, especially in Kiyushiu, I have often seen Ginkgo trees well over a hundred feet in height. At a little distance they rather resemble Poplars.—J. H. D.

FORTHCOMING EVENT.

January 19.—Royal Horticultural Society's Fortnightly Meeting and Exhibition, Vincent Square, Westminster, 1 to 5 p.m.

SOME HARDY LILIES.—III.

SUB-GENUS EULIRION.

(Continued from page 16.)

Lilium regale, introduced from Western China about the end of last century, is the most valuable addition to the list of cultivated Lilies that has been made since Messrs. James Veitch and Sons brought over *L. auratum* some thirty years earlier. It was named at first *L. myriophyllum*, but is quite distinct from Franchet's Lily of that name. It well merits its new title—the Royal Lily—for it is a truly splendid thing, and possesses, in addition to singular beauty, a fine constitution, qualifying it to take rank among the easy Lilies. It demands much the same treatment as *L. auratum*, except that it relishes lime, which the other detests. Let the bulbs be kept in pots till they form basal roots freely; then for permanence plant them out deeply in generous, loamy soil with an admixture of ground limestone. The drainage must be perfect, although this species is not nearly so liable to injury from winter wet as some of its congeners. The Royal Lily has affinities with the tender *L. longiflorum* and the more or less hardy *L. Brownii*; but is easily distinguished from both when growing by the densely crowded linear leaves that clothe its 3-foot stem. The snowy perianth is more or less splashed with maroon outside and richly suffused with gold within the throat. The flowering season is in July.

L. rubellum is as coy and capricious as *L. japonicum* (Krameri), whereof it is a miniature in form and colour of flower. Being quite frost-hardy, if it could be sent from Japan by some friendly hand soon after the flowering season is over—that is, in early summer—it might prove a less difficult subject; but it has to wait till the usual autumn and winter exports are despatched, by which time the small bulbs are in the worst possible condition to encounter the wet and cold of our climate. The best chance of

success is with bulbs raised from seed, and these should be treated as miniature *L. auratum*, deeply planted in well-drained loam, and, in the Southern Counties at least, half screened from scorching sun. Here it may be noted as applying to all Lilies, as well as to every other plant cultivated in gardens, that no uniform prescription can be offered for the amount of exposure to sunlight, so greatly is the power of plants to profit by it or endure it modified by conditions of soil and atmosphere. On cool loam with a cooler subsoil, vegetation will revel in an amount of sunshine that would parch it to tinder on heavy clay or hot chalk. Latitude and longitude also enter into consideration. In the humid West the sunlight is seldom of so searching a character as in the Midlands or on the Eastern and Southern Coasts of England; so that all general directions for the cultivation of shrubs, herbs and bulbs should be read in relation to the meteorology of the district where they are to be grown. *L. japonicum* and *L. rubellum* being the only pink Lilies known, it is hard that we cannot have them at beck and call. Howbeit, there is no reason to despair of solving some day the enigma of their

nature, and it is of hopeful augury that seeds are so freely produced.

L. Sargentiae.—A noble Chinese Lily, until lately reputed a variety of *L. Brownii* under the epithet *leucanthum*, but now admitted to the dignity of a distinct species. It requires much the treatment as *L. Brownii*, and has thriven and flowered well with me in strong loam with sand and lime. The shape of the flowers is much the same as in *Brown's Lily*; but they are gilded outside instead of stained with purple, their appearance being strongly suggestive of carved ivory. This Lily seems to have come to stay, and it unites with its other virtues that of producing innumerable bulbils in the leaf-axils, after the manner of the Tiger Lily. It is, however, somewhat impatient of winter wet, and should be planted 6 inches below the surface on inverted pots, where rapid drainage cannot otherwise be had. It loves lime, and flowers ten days or so later than *L. regale*.

SUB-GENUS ARCHE-LIRION.

L. auratum, the Japanese Hill Lily, is quite the most gorgeous of all flowers hardy in the climate of the British Isles. Among the manifold benefits conferred upon horticulturists by the famous firm of James Veitch and Sons, none shines more conspicuous than their introduction of this splendid plant to our country a little more than half a century ago. That space of time has hardly sufficed to make gardeners in general familiar with its requirements. Of the millions of bulbs imported every year, a very small proportion survive through a second season, else our land would be full of them by this time. Yet the conditions it demands are simple; indeed, my experience of it in the humid atmosphere and cool soil of the West Coast has taught me to regard it as one of the easy Lilies. These conditions are—careful scrutiny on arrival for the detection of fungoid or animal parasites, washing in a 1 per cent. solution of salicylic acid, potting, and keeping in a cold frame till growth starts in spring. If by that time plenty of strong basal roots have been formed, the bulb may be planted 8 inches or 9 inches deep in sound loam with a liberal admixture of sharp sand, pulverised peat or leaf-mould, wood-ashes and no lime. But if, as is probable, the pots contain only stem roots, one must find patience to wait another year before the plants are allowed to flower. The pots should be plunged in the open border, sheltered from scorching sun, and disbudded so soon as they prepare to flower; otherwise flower they will, at the cost of permanent vigour, and perhaps of their further existence. In the following season these bulbs will have filled the pots with basal roots, and should then be planted out in such surrounding that, when the flowering

stem rises, it may meet free air and sunshine, while the root is screened from parching by lowly undergrowth. So treated, this grand Lily comes up year after year, and flowers as lavishly as on the volcanic slopes of its native Fusi-Yama and rising to a far greater height than it does there.

Some good authorities have expressed distrust of peat, preferring leaf-mould. Of course, there is peat *and* peat, especially in the North, where it is often indigestible and reeking with humic acid; but in my opinion peat of good quality, finely pulverised and mixed with one-third its bulk of sand (sea-sand answers perfectly in default of silver sand) cannot be beaten. I have a notion

bulbs have never received any nourishment save what is contributed by the natural leaf-fall of the Rhododendrons. It is sometimes recommended that farmyard manure be laid below the bulbs when planting them. A risky proceeding! Scrupulous care should be taken not to allow it to be in contact with the bulbs. The safer plan is to withhold all manure, except wood-ashes, till the second year, after which top-dressing will stimulate growth and flower production, as it does in the case of all stem-rooting Lilies. There are several varieties of *L. auratum*, far the most vigorous and easily grown being the golden-rayed kind sold as *platyphyllum* (broad-leaved), termed by botanists *macranthum* (large-flowered). Some of the stems in our irrigated border are now (July, 1914) more than seven feet high.

In *rubro-vittatum* (red-banded) the golden streak down the centre of each segment of the perianth is exchanged for glowing crimson. It is less robust than *macranthum*, with smaller bulbs, narrower leaves and humbler stature. Mr. Grove inclines to regard it as a hybrid between *L. auratum* and *L. speciosum*.

In Southern England *L. auratum* often ripens seed, but in Northern districts, where it does not flower till August and September, I have never known it to do so. Propagation, however, is easily effected by breaking up a bulb and planting the scales in a cold frame, where each scale will develop into a perfect bulb. Once the bulbs are established in the open ground, they ought to be left undisturbed; but if it becomes necessary to move them, they should be carefully examined before replanting, for it often happens that small bulbs are formed among the stem roots. Each of these should be carefully preserved and nursed to maturity. Anybody who has had to remove established clumps of *L. auratum* must have been struck by the great depth to which the bulbs have retreated. The presence of tree roots in the soil is no detriment to them; on the contrary, it affords them friendly protection. Of course, these roots impoverish the soil, but that can be met by top-dressing, for it is through the stem roots that nourishment is drawn to the inflorescence. Gardeners accustomed to grow this Lily for a single season's display in the open, or in pots for decoration of the house or conservatory, may consider the process above described both laborious and superfluous; but the Hill Lily of Japan is far too precious to be treated like Hyacinths and other bedding bulbs—brought into flower once and then thrown out on the rubbish-heap. Properly treated, it is one of the most permanent of perennials, and would soon become as common in this country as the Orange and Tiger Lilies if its requirements were more generally understood and provided for.

HERBERT MAXWELL.

(To be continued.)

A FLOWERING TREE OF MORELLO CHERRY TRAINED ON A WALL WITH A NORTH ASPECT. TREES MAY BE PLANTED NOW. (See page 29.)

that the antiseptic properties of peat are some safeguard against fungoid mischief, and I cannot but suspect leaf-mould as a harbour and vehicle of that dire bogey of the Lily-grower, *Botrytis cinerea*. Eight or ten years ago I set some *L. auratum* bulbs in a Rhododendron border of peat and sand on a subsoil of boulder clay. They have never failed to bloom splendidly, rising to a height of 6 feet, the only attention they have received being to cut back the Rhododendrons to give them headroom. They ought, by rights, to have had an annual mulch of a stimulating kind, for *L. auratum*, after it is well established, relishes a generous diet; but these particular

APPLES AND PEARS: FLAVOUR AND PEDIGREE.

IN a recent article under this heading—see page 595, issue December 12, 1914—Mr. Chapman deplores the lack of more detailed records in the history of our popular fruits, and emphasises the fact that breeders must keep flavour before them as their most important aim. I find myself quite in agreement with him, but I think that usually records such as we generally have put before us are of little value. The parents are often discovered after the event, and in many cases can only be termed “putative.” Even where there exists no doubt at all, the value of a single isolated cross between A and B gives but little guidance to the serious cross-breeder. For this information a large number of crosses between two varieties would be of very great interest. Happily, such a series does exist, and to further Mr. Chapman's aims I venture to give some particulars of this extremely valuable experiment.

This work was carried out at the Geneva Experiment Station, New York, by Professors Beach and Hedrick, the crosses having been started in 1901. The special feature of these trials, as is indicated above, was that a considerable number of crosses were made between two varieties, and as many as twenty-nine trees were obtained of Esopus × Ben Davis, and twenty of Ben Davis × Mother. Contrary to accepted ideas, all these trees bore fairly good fruits. The appearance of Crabs, as so often alleged, in beds of seedling Apples is exceedingly doubtful, and a demonstration of their existence would be of great interest.

Let us take the Ben Davis × Mother cross and examine the seedlings. If these were arranged in a series for shape and appearance, placing those resembling either parent at the extremes of the line, graduated forms would be found leading from one to the other. For instance, one Apple resembled Mother almost exactly, while others were intermediate in shape but had the flesh of either one parent or the other. Thus, a Ben Davis fruit *externally* would have the Mother flesh and *vice versa*. All the fruits could quite easily be referred to one parent or the other. No Crabs or unexpected types appeared. The great importance of this will be at once apparent. The various qualities were mixed up as two packs of cards might be mixed, and sometimes the individual qualities were blended as in one fruit where the flesh was intermediate. The way before the Apple-breeder is therefore clear. A large number of one cross must be made, and there will be a good chance of the desired mixture of qualities turning up. There is a large amount of evidence that many, if not most, of our garden fruits will breed nearly true where they are self-fertile, and the results detailed above confirm this expectation. It will be interesting briefly to summarise the inheritance of certain characters as they behaved in these experiments. These cannot yet be regarded as more than helpful suggestions; their elevation to the rank of facts will require further confirmation.

Vigour.—Nearly all hybrids were more vigorous than the parents.

Shape.—This is evidently a complex affair, but the parental forms appear with many grades between.

Colour of Fruit.—Fruits which are yellow and red flushed are heterozygous; fruits where red predominates may be homozygous or heterozygous. Yellow is probably always recessive.

Flesh.—This may resemble either parent or be intermediate.

Acidity.—All the experiments dealt with sub-acid fruits, but the seedlings were mostly on the sweet side.

Season.—This is probably inherited. From crosses of late Apples, only late fruits have been produced. This character, therefore, is probably recessive.

One more hint may be given, and that is that breeders should not give up hope because a tree gives small or indifferent fruit at first. Fruit trees often take some years to attain maturity and a settled line of conduct. A young tree may

in a raw state, they are superb when cooked, either in pies or stewed, and those who have once tasted them served in this way would never tolerate the insipid and anæmic Sweet Cherries that are so frequently used in the kitchen. The Morello or Pie Cherry does not present any serious cultural difficulties. It will thrive in almost any good garden soil, and for that reason is an ideal fruit for the amateur to grow. Trees may be planted at any time from November to March, the soil having been previously well dug and some old mortar or other form of lime added. As this Cherry fruits entirely on the young wood made the previous year, pruning must consist of cutting away that which has borne fruit, retaining as many young shoots as possible. This old wood is best cut away as soon as the fruit has been gathered, thus giving the young growths a better opportunity to become well ripened. Grown against a north wall, the fruit will remain good until early September, providing it is protected from

ONE OF THE MOSSY SAXIFRAGAS: *S. PEDEMONTANA CERVICORNIS*. (See page 31.)

have very hazy ideas of its correct season of ripening for a few years, but with adolescence comes stability. Many must have been the seedlings which have been discarded because they did not at once fulfil the bright hopes of their raisers. Young swans are not so very unlike young geese, and time will allow them to settle the question for us.

The problem of what varieties to breed from is a hard one which cannot be treated here, but it would be as well to remind intending breeders that Cox's Orange is not the only good-flavoured fruit. Many of the older fruits have a flavour all their own, and are worth exploiting.

EDWARD A. BUNYARD, F.L.S.

MORELLO CHERRIES FOR NORTH WALLS.

FOR planting against a wall or close-boarded fence with a north aspect, there are few more useful subjects than the Morello or Pie Cherry, a fruit that is not grown nearly so much as it ought to be. Although the rich red fruits are very acid

birds. Although an ideal fruit for the position named, it may be grown as a bush in the open, or against walls or fences with east or west aspects. Its chief enemy is black fly, which often attacks the young shoots severely, but this can be kept down by prompt syringing with any approved insecticide.

G. B.

HOW TO PRUNE GRAPE VINES.

A FEW weeks ago an amateur cultivator was inspecting some young Vines I had planted last winter. Some of the young rods had grown 20 feet long during the summer months. These were leading rods. There were also two or three side rods, as the intention of the writer is, in due course, to train up three rods from each Vine. The amateur referred to possesses a large vinery, in which, also, Peaches are grown. He put some questions to me respecting the pruning of Vines, and was amazed to learn that the Vines would this winter be cut back, leaving only about

eighteen inches or two feet of the current year's growth. His own Vines had never been hard pruned, consequently they had become overcrowded, and each year the crop of fruit was more and more, but of poor quality. Now, hundreds of amateur cultivators will be busy cleaning and pruning their Vines at this, the beginning of the new year, and there is no time to lose. Very late pruning is undesirable, as there is always a danger of losing much valuable sap when it rises in spring; when the pruning is done early in January, the severed vessels have time to close before the sap begins to flow. In the case of young Vines, especially, it is advisable to paint

EARLY FLOWERING SAXIFRAGES.

SAXIFRAGES or Rockfoils comprise a wide range of beautiful and interesting plants, most of which are of the easiest cultivation. One has only to make a few comparisons to realise the great diversity of form that exists among Saxifrages. For instance, the genus includes dwarf mountain species like *Saxifraga aizoides*, native of the mountain rills of Scotland, and *S. cordifolia*, the Giant Rockfoil of Siberia. Other contrasts

between *S. rocheliana* and *S. sancta*. Like the last named, which is also a desirable early Saxifrage, it is classed among the Spiny Saxifrages. It is not likely to become scarce in cultivation, for it grows with great freedom and appears to be quite capable of taking care of itself. It shows preference for a limestone soil and is well suited for the sunny side of the rock garden. The white variety, *alba*, is worthy of special note.

S. Boydii.—This rather scarce plant is said to be a hybrid from *S. burseriana* and *S. aretioides*. The round yellow flowers rise an inch or so above the cushion-like growths. The variety *alba* has pure white flowers and is greatly cherished by all lovers of alpine plants. Faldonside is a comparatively new variety, with clear yellow flowers of good form. Flowering season, April.

S. burseriana.—No Saxifrage has created so much interest in recent years as this. It is one of the loveliest of the early flowering alpine, and bears a profusion of snow white flowers arising from very spiny tufts. There are many varieties, of which *Gloria* is the best. There is, however, great variation in the species, some varieties having much larger and better formed flowers than others. It must be given a dry position free from any trace of stagnant moisture. It may be grown in full sun or partial shade, the best position being a much-discussed point.

S. Grisebachii.—A very distinct introduction from the Balkans. It sends up bright crimson flower-spikes from small rosettes of foliage. So far it has proved difficult to cultivate, at least in many localities. It must be given a dry position, and is best when grown upon a small cone of stones. It is one of the earliest to flower, and as a rule commences to push up its bright flowering growth in February and lasts until April.

S. Haagei.—A hybrid of garden origin having deep yellow flowers. It forms a companion plant to the paler-coloured *S. apiculata*, both flowering together and requiring similar soil and position.

S. ligulata (Nepaul Rockfoil).—If this species were a little hardier it would prove one of the most valuable of the large Rockfoil or Megasea section. It produces branching panicles of rosy flowers in April. In a mild spring it is a plant of rare beauty. It should be given a sheltered position on a warm sandy soil facing south.

S. longifolia (Pyrenean Rockfoil).—Rightly termed the "Queen of the Saxifrages," this species is one of rare and refined beauty. It should be grown in crevices between vertical rocks, so that water cannot collect in the hollow rosettes. When in bloom it is most attractive, forming a long pyramidal truss of white flowers usually in June and sometimes later. Plants collected from the mountains are often slow to produce their trusses of bloom, as they frequently remain stationary for a year or two and then give a moderate account of themselves. Seedlings, however, vary in their early growth, some running away to a precocious flowering, and others flowering after six, seven or even eight years' growth; but the stronger the

A FINE PLANT OF THE PYRENEAN ROCKFOIL (*SAXIFRAGA LONGIFOLIA MAGNIFICA*).

the cut ends forthwith with painter's knotting; this sets hard immediately and closes the pores or sap channels in the canes. Vines newly planted should be cut back level with the wall plate—the point where the glass begins. Vines that have been planted one year should be cut back to about twenty inches of the base of the current year's growth; the leading rods of all Vines must also be treated in this way. Laterals growing from spurs at the sides of the rods are best pruned back to two buds. When the latter break in spring, the cultivator will soon be able to determine which one will bear the best bunch of Grapes; then the other shoot can be rubbed off. Even if there are no bunches on either shoot, the best can be retained, as the necessary disbudding must be done before the young shoots are 2 inches long.

Forming Spurs on Young Vines.—Of course, the side spurs could be measured out exactly; but they can be formed almost as desired. The best average distance apart is 18 inches. Twenty inches will do, or even a little more. The spurs should be formed alternately on both sides of the rod; then as the young shoots grow from them they will dovetail in and so cover the roof space evenly with good foliage. Use a very sharp knife and do not cut too close to the bud left.

G. G. B.

may readily be found among *S. sancta*, a dense tufted species from Mount Athos; the pyramidal *S. Cotyledon* of the Alps; *S. peltata*, the Umbrella Plant of California, one of the largest species of the genus; *S. sarmentosa*, known by a variety of names, including Mother of Thousands, Aaron's Beard, Creeping Sailor and Wandering Jew, often seen in sitting-rooms or as basket plants in cottage porches; and last, but not least, the ever-popular London Pride (*S. umbrosa*), which in some parts of the country still retains the name of None So Pretty. So great is the variety that one might have a garden of Saxifrages alone, and even then have flowers for the greater part of the year. The earliest flowering Saxifrages are for the most part true alpine, and it is to these that special attention is now drawn, for they are indispensable to the rock garden in spring.

Saxifraga apiculata.—This is well known to be one of the earliest to flower, and even when not in flower its dense foliage, carpeting bare ground and clothing rocks and banks in summer and winter, makes it in every way a desirable plant for the rock garden. The flowers are pale yellow and borne in the greatest profusion from the early days of March till the end of April. It occurs wild in the Pyrenees, but is thought to be a hybrid

rosette of leaves the better will be the inflorescence. The variety *magnifica* forms an imposing rosette, often more than a foot in diameter. The plant illustrated is believed to be about fifteen years old. As usual, the plant died after flowering and producing seeds.

S. marginata.—A very beautiful Italian species flowering from March till May. It is a close-growing, tufted species with pure white flowers. It is the parent of a number of early flowering hybrids, all of which, like the species, should be grown in a gritty soil on a rocky sheltered ledge, where they receive the full benefit of the morning sun. Propagation is effected by division in spring after flowering, or by cuttings taken in the summer.

S. oppositifolia.—A very beautiful and distinct species, and certainly not difficult to grow. It is found growing wild on the mountains of North Wales and in Scotland. It will grow in either shady or sunny positions, but it flowers far better when grown in full sun. The flowering season is March and April. The type has purplish rose flowers, but the varieties *coccinea* and *splendens* are both richer in colour; *alba* is a fine white variety. The species is of creeping habit and requires a similar soil to that recommended for *S. apiculata*.

S. pedemontana cervicornis.—Few of the Mossy Saxifrages are so compact in growth and none so pretty when in flower. It is truly alpine, and is found in the mountains of Sardinia and Corsica, where it ascends to elevations ranging from 4,800 feet to 7,500 feet. It is perfectly hardy and is not affected by cold, but rather by the mildness of our winters, which sometimes excites it into untimely growth. In winter the leaves of the dense rosettes overlap one another like the slates of a roof. The flowers are loosely arranged and borne in May. In lowland gardens they rise 4 inches or 5 inches from the ground, and this is about twice the height attained in their mountain homes.

S. Wallacei.—One of the most robust and profusely flowered species or hybrids of the Mossy section. It is so easily grown that it is used extensively as an edging in the London parks. It prefers a light soil and fairly sunny position, and produces masses of white flowers in April and May.

Although the majority of Rock-foils bloom in spring, there are others quite indispensable for later flowering. The summer-flowering *S. Cotyledon*, with robust, erect sprays from 1 foot to 4 feet long, is worthy of special mention. Of the very late flowering species, *S. Fortunei* and *S. cortusoides* will prolong the supply of bloom from August till October if given partially shaded positions and a gritty, but at the same time fairly rich and well-drained soil. The family is rich in interesting and beautiful species, the cultivation of most being comparatively easy, though a few of the rarer kinds present some difficulties. Just now the vivid green tufts of those belonging to the Mossy section are very attractive in the rock garden.

C. Q.

THE SNAPDRAGONS AND THEIR CULTURE.

ALTHOUGH the Snapdragons, as we are pleased to call the flowers that the botanists class as *Antirrhinums*, have been known in our gardens since the days when Gerard wrote his famous herbal, it is only during recent years that any great improvements in colour, habit and form have been effected. In the early days already referred to there were, according to available data, four varieties, viz., *album*, *purpureum*, *variegatum* and *luteum*, the colours of which are well described by their names. These were undoubtedly the forerunners of the modern race that is now so highly appreciated in our gardens, and all of which have descended from the species *Antirrhinum majus*.

Fortunately, the cultivation of the ordinary Snapdragons does not call for any special skill or treatment on the part of the gardener. I use the word "fortunately" advisedly, because

plant, and in a wild or semi-wild state is usually allowed to grow as such, the gardener generally finds it more convenient to treat it as an annual, or at the most a biennial, for the purpose of filling beds or planting in borders. It is such a good-natured plant that it readily lends itself to this treatment, and the modern varieties have been so carefully selected that most of them can be relied upon to come true from seed.

There are two methods of raising seedlings; one is adopted where the plants are to be treated as annuals, and the other if their existence is to extend well into the second year, though either would be applicable were it desired to allow the plants to remain as perennials. To treat them as annuals—i.e., to raise the plants from seed, allow them to flower, and discard them all in one year—it is necessary to sow the seed early in the year, and the latter part of January or the early days of February is usually selected as the most appropriate time. By sowing the seed so early a long period of growth is secured, a feature that is necessary with these plants. The actual sowing of the seed and raising of the seedlings

SAXIFRAGA GRISEBACHII, A RARE ROCKFOIL FROM THE BALKANS.

these flowers are so useful for so many purposes in our schemes of summer and autumn effects that they should find a home in every garden, no matter whether it be the strip of the suburban villa or the demesne of the mansion. For filling beds or borders, for naturalising in the wild garden, the crevices of dry walls or inaccessible rocks, the Snapdragons are admirably adapted, and in the latter positions they will usually sow and reproduce themselves freely when given a good start. In the gardens at Hopetoun House, Linlithgow, whole borders are devoted to these flowers, large masses of one colour being planted, and a wonderful colour effect thus obtained. Although the Snapdragon is really a perennial

present no serious difficulty. A quite cool greenhouse or frame is essential, and the boxes or pans in which the seed is to be sown must be well drained, as Snapdragons are greatly averse to excessive moisture. The soil for filling the boxes ought to consist of good loam two parts, coarse grit one part, with a little leaf-soil and some old mortar added. A similar mixture, except that a little old, well-decayed manure should be substituted for the leaf-soil, may be utilised in which to transplant the seedlings when they are large enough to be conveniently handled. Thin sowing of the seed, early transplantation of the seedlings, and, above all, cool, airy treatment throughout the whole of their career, are the passports to success

in the raising of Snapdragons from seed early in the year. If kept near the glass and freely ventilated, as advised, the young plants should be sturdy and branching by the end of May, at which time they may be planted in their flowering quarters.

If we desire to treat Snapdragons as biennials, *i.e.*, raise them one year to flower the next, the seed may be sown in June in the open garden, and the seedlings subsequently transplanted to where they are to flower. Thin sowing and prompt transplantation are essential. So far as soil is concerned, these delightful flowers are not at all fastidious, but it must not be heavy clay that is water-logged. Thorough drainage, and a fair depth of loam to which has been added a goodly proportion of well-decayed manure, will give large spikes of glorious flowers. But, on the other hand, dry, starved soil will produce bushy plants that never seem to tire of flowering, and for this reason the Snapdragon is an excellent plant for growing in the warm, dry borders that are usually found surrounding the dwelling-house, for dry walls, or for rockwork where there is very little soil. In such situations it is best to sow the seed in June where the plants are to grow and flower, and allow them to remain as perennials.

Of modern varieties there are a great many, and nearly every seedsman has his own speciality. The beautiful art shades of pink, gold, terra-cotta and bronze have created a great deal of interest in recent years, and are all well worth growing in masses in beds or borders.

W. H.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE amateur cultivator wishes to grow varieties that are of high merit, both as regards quality of flower as well as form of plant, and fairly easy to manage in all stages of development from the cutting to the flowering stage. The following varieties are sure to give every satisfaction.

Twenty-Four Japanese for Large Blooms and Groups.—Miss A. E. Roope, golden yellow; Queen Mary, pure white; Mrs. G. Drabble, white; His Majesty, rich velvety crimson; William Turner, white; H. E. Couverse, reddish bronze, with a gold reverse; Kara Dow, chestnut bronze, with a gold reverse; Rosamund, primrose, shaded old rose; F. S. Valis, lemon yellow; Bob Pulling, rich yellow; Frances Jolliffe, straw colour, streaked rose pink; Marie Loomes, terra-cotta red; Mrs. James Gibson, mauve pink on white ground; Mrs. E. A. Tickle, mauve pink; Mrs. T. Stevenson, rich yellow, sometimes tinted buff; Master James, chestnut; Mrs. A. T. Miller, pure white; Mrs. J. Lloyd Wigg, yellow, shaded buff; Maud Lousada, rosy mauve on white ground; Amy Poulton, rich pink; Miss Elsie Davis, rosy mauve; Mrs. K. Luxford, pure white; Alice Lemon, mauve pink; and Fred Green, rich purple. The height of these varies from 3 feet to 5 feet.

Twelve Varieties for Decoration.—The following varieties are splendid for decorative purposes in pots or as cut flowers, and are available from October to Christmas: Mrs. George Rundle, white; Source d'Or, orange and gold; Crimson Source d'Or; Caprice du Printemps, rosy pink; Mrs. Roots, pure white; Embleme Poitevine, yellow; Mme. R. Oberthur, white; Mrs. J. Thompson, white; Nagoya, yellow; Dr. Enguehard

pink; Baldock's Crimson; and David Ingamells, yellow. The varieties Mme. R. Oberthur, Source d'Or, David Ingamells, Mrs. Roots, Caprice du Printemps and Mrs. George Rundle may be planted out in the summer, lifted either before or after the buds are well set, and repotted.

Twelve Single-Flowered Varieties.—Mensa, pure white; Ceddie Mason, chestnut crimson; Mary Richardson, reddish salmon; Altrincham Yellow; Mrs. Tresham Gilbey, yellow; Sylvia Slade, rosy garnet, broad white ring round the disc; Metta, deep magenta; Kitty Bourne, deep yellow; Florrie King, pink; Roupell Beauty, dark plum colour; Joan Edwards, pink; and Charles Kingsley, rich yellow. The varieties Mary Richardson, Ceddie Mason, Joan Edwards and Altrincham Yellow are very attractive grown as sprays, but all may be disbudded. These will afford a supply of blooms from mid-October till December. I will give a list of varieties for the garden borders in a later issue.

AVON.

A WIGTOWNSHIRE AMATEUR HORTICULTURIST.

AMONG ardent cultivators of their picturesque gardens in South-Western Scotland, none is more entirely worthy of admiration than my nearest neighbour, Mr. John Hill, mechanic, tender lyrist and earnest horticulturist, residing within the environment of the Manse in the parish of Kirkmaiden. During the summer and autumn months his garden, which, though not extensive, is intensely attractive by reason of its prevailing brightness and fragrance, is greatly admired by all visitors (and they are many) to this peninsular region. Mr. Hill, who is, as I have indicated, an assiduous gardener, though he has not so much leisure as most of us for this peaceful, eminently healthful and refining occupation, may be described as a highly successful cultivator of Irises, Rhododendrons, Azaleas, Hollyhocks, Sweet Peas, Roses and Oriental Lilies. The soil in which he grows them is a fertile loam.

In many instances the herbaceous flowers appear to succeed in his garden most admirably when they are left by their proud possessor, severely alone. Such beautiful and accommodating Lilliums, for example, as szovitzianum, candidum and chalcedonicum (the brilliant Scarlet Martagon) are not seldom most enduring and luxuriant in their blossoming when they are utterly undisturbed. They are, in my experience, in many instances as sensitive as human beings, possessing delicate nervous and mental organisations, especially at the roots, where some of them will hardly tolerate division at all. Many of the most precious herbaceous plants in this unique garden have flowered profusely in the same soil for the last ten years. This horticultural Art "itself is Nature," as Shakespeare sings.

The climbing Roses, especially those of wichuriana origin, are commandingly profuse and prodigal in their affluence of bloom. Such Hybrid Perpetuals and Hybrid Teas as Victor Hugo, Duke of Edinburgh, Frau Karl Druschki, Viscountess Folkestone, Margaret Dickson and the highly distinctive Lyon Rose are usually among the most effective and fascinating varieties of the Queen of Flowers in Mr. Hill's garden, which (perhaps the Editor will permit me to add) has been greatly admired by such enthusiastic amateur

horticulturists as Mrs. McDouall of Logan and the Earl and Countess of Stair. Among the Indian, Levantine and Japanese Lilies that have been successfully cultivated by Mr. Hill are the Himalayan *Lilium giganteum*, *L. auratum*, *L. tigrinum*, *L. speciosum* and *L. chalcedonicum*. I have great pleasure in thus testifying in the columns of THE GARDEN to his unquestionable merits as a floral cultivator; for Mr. Hill is one of those whose hearts and lives seem echoes of those glorious lines of Wordsworth:

"Thanks to that human heart by which we live,
Thanks to its tenderness, its joys, its fears,
To me the meanest flower that blows can give
Thoughts that do often lie too deep for tears."

DAVID R. WILLIAMSON.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Cypripedium Grand Duke Nicholas (*C. Actæus* var. *Miss F. H. Camm* × *C. leeanum* Carona).—In the handsome, well-developed dorsal sepal, which is broadly margined white, there is a considerable leaning to the best of the *leeanum* class, than which few present bolder proportions generally. The sepals, petals and pouch are of greenish yellow tone. From G. F. Moore, Esq., Bourton-on-the-Water.

AWARDS OF MERIT.

Cypripedium Pyramus Chardwar Ideal (*C. Miss Mostyn* × *C. Hera Euryades*).—In this the pronounced white dorsal sepal is heavily blotched chocolate, sepals and petals rich chestnut, and pouch dark brown. Exhibited by G. F. Moore, Esq., Chardwar, Bourton-on-the-Water.

Cypripedium arthurianum Langley Variety (*C. fairieanum* × *C. Harefield Hall*).—This fine hybrid embraces some of the characteristics of both parents, the dorsal sepal partaking of the last, and the sepals and petals of the first named. It is a well-marked flower. From Messrs. Flory and Black, Langley, Slough.

Odontoglossum eximeum Xanthotes Gatton Park Variety.—A splendidly flowered raceme of this novelty was shown. It is a flower of singular whiteness and purity, the sepals and petals touched with a faint yellow shade and with a yellow crest. From Sir Jeremiah Colman, Reigate.

Cymbidium coningsbryanum Brockhurst Variety (*C. grandiflorum* × *C. insigne superbum*).—A well-developed, freely flowered specimen of this hybrid was on view. The spike is erect, arching above, and bearing many handsome flowers. The latter are of almost shell pink hue, the lip copiously spotted crimson. Exhibited by F. J. Hanbury, Esq., Brockhurst, East Grinstead.

Pyracantha crenulata.—The specific name is not particularly appropriate, some leaves being devoid of the crenulated margin, while others are well marked. Of this Veitchian introduction from Western China, a 12-feet-high, pyramidally inclined specimen having a basal diameter of 6 feet was shown. Bushy at the base and tapering upwards, it was abundantly fruited throughout the somewhat pendent branches of 2 feet or so in length, loaded with smallish fruits coloured a reddish-scarlet. The 2-inch to 3-inch long leaves are half an inch broad, linear obtuse, shining green above and greyish beneath. Shown by the Hon. Vicary Gibbs, Aldenham, Elstree.

The whole of the above were shown before the Royal Horticultural Society on the 5th inst., when the awards were made.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Pot Vines.—The shoots on Vines which were started early in November should now be finally thinned. Pinch the laterals at the second leaf beyond the bunch, and keep them from touching the glass by tying them carefully to the trellis. The roots may be given a little stimulant now in the form of liquid manure and soot-water. Keep a moist atmosphere by damping down the walls and paths in the house, more or less if the weather is dull or fine. A minimum temperature of 65° will now be suitable. Admit a little air whenever the weather is fine, but close the ventilators before 2 p.m.

Early Permanent Vines.—The weather has been very favourable for forcing, as little fire-heat has been necessary to keep up the temperatures. Rub off all useless growth, but defer the final thinning of the shoots till it can be seen which are the most promising. Before the Vines come into flower, examine the borders to see if they require water.

Plants Under Glass.

Schizanthuses.—The plants which were raised from seed sown in the autumn must be kept growing in a cool house with plenty of light. Water carefully, and admit plenty of air to the plants whenever the weather is suitable. Use fire-heat sparingly at all times.

Mignonette.—Another sowing of this delightful greenhouse plant may be made now in 2½-inch pots. The autumn-sown plants must be kept growing on a shelf near to the glass in a cool house. When the flowers begin to develop, afford the roots some stimulant in the form of liquid manure and soot-water.

Cinerarias.—Do not let Cinerarias become too dry at the roots, and when they have become well rooted in their final pots give them plenty of stimulants. An occasional light fumigating will ward off attacks of aphids. A house or pit which is frost-proof will suit this plant well.

Chrysanthemums.—Remove the cuttings to a shelf in a cool house when rooted, but do not expose them to cold draughts. Keep old stools which are required for stock in a light, cool house to encourage sturdy growth.

The Flower Garden.

Bedding Plants.—Attention must now be given to the various plants which were rooted from cuttings in the autumn. Those which were rooted in boxes or pans, such as Pelargoniums, Fuchsias, Lantanas, Salvias, Iresines and Ageratums, may be potted into 3-inch pots and placed on a stage in a fruit-house which has just been started. Cuttings of various bedding plants which are available will readily strike now if placed on a hot-bed in the propagating-case. *Salvia Glory of Zurich* may be raised from seeds sown now. I find the plants raised in this way are quite equal to those raised from cuttings in the autumn. *Marguerite Mrs. F. Sander* is a most useful bedding plant, and good plants may be grown from cuttings inserted now. They will require to be stopped two or three times to encourage a dwarf, bushy habit.

Sowing Seeds.—Towards the end of the month seeds may be sown of the following: *Wigandia*, *Canna*, *Begonia* (both tuberous and fibrous rooted), *Delphinium*, *Hollyhock*, *Verbena*, *Antirrhinum* and *Centaurea*. Sow the seed in fine sandy soil in well-drained pans or boxes, and place them in a brisk heat till the seedlings are through the soil.

The Rock Garden.—After spells of severe frost it is necessary to carefully examine the smaller plants, pressing the soil about the roots where it has been lifted by the frost. In some cases it may be necessary to place a little fresh soil around the plants for protection. A great many plants will be needed to furnish the rock garden during the coming season, some of which may be raised from seed sown during the next few weeks.

The Hardy Fruit Garden.

Morello Cherries.—The pruning and training of these must be no longer delayed. The Morello

Cherry lends itself admirably to training, and makes a very handsome tree when the work is well done. Remove branches which are becoming bare at the base, so that the trees may be well furnished with young fruiting wood, and guard against overcrowding.

Renovating Old Trees.—Much may be done to help old trees to retain their vigour during the winter months. It is not always prudent to disturb the roots of very old trees to any great extent, and, when this is so, an effort should be made to encourage fresh roots on the surface. A portion of the old surface soil should be removed, exposing the roots as much as possible, and replace with fresh loam, old brick rubble and wood-ashes.

The Kitchen Garden.

Potatoes.—The tubers which are intended for planting in pits or frames should be placed on end in boxes to sprout. In the meantime the pit should be prepared. A hot-bed of leaves and stable litter must be made on which to place the soil. This will be all the better if placed in the pit a week or ten days before planting the tubers.

Lettuce.—Plants in frames must be given plenty of air during mild weather, and decayed leaves must be removed regularly. Make a sowing of a suitable variety for frame culture in boxes, and place them in a moderately warm house.

Carrots.—Make a sowing of these on a hot-bed in a frame. A depth of 6 inches or 7 inches of rich soil must be placed on the hot-bed and made fairly firm. Level the surface with a rake, sow the seed broadcast, and cover with fine soil.

Radishes.—To keep up a regular supply, make small sowings every week or ten days. Radishes require a fairly rich soil and plenty of water when growing. They may also be sown with the Carrots.

E. HARRISS.

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Mignonette.—The plants which were raised from seed sown during August or September and which have been growing in a cool house or pit will be ready for moving into their flowering pots. For potting use a rich compost containing a fair quantity of some reliable fertiliser.

Sweet Peas intended for flowering indoors during April and May should now be ready to plant in their flowering quarters. Plenty of root-room is necessary, but too much artificial heat must not be used. Flowers of better quality on long stems result from a judicious disbudding and regulation of the plants as they grow.

Gloxinias.—A batch of these may be started in the stove for early flowering, placing the tubers in light soil in pans or boxes. When ready for potting, use the loam in a rather rough state, and include a large quantity of leaf-mould, peat and coarse silver sand. Young plants that will flower in July and August are to be had by sowing seed this month.

Violets.—It is important that Violets be ventilated freely during mild weather. Even during periods of frost the frames should be opened when the temperature exceeds 32° in the sun, although this may only be for one or two hours in the middle of the day. It will be readily seen how essential it is for a Violet frame to have a south aspect, besides having a good pitch.

The Hardy Fruit Garden.

Red and White Currants.—As Red and White Currants produce their fruit on the old wood, cut back all last year's growths to about three eyes, leaving young wood only where it is needed for the formation of the bush.

Black Currants.—These do not require so much pruning except the removal of old and weakened branches. All the young wood possible should be encouraged. If big-bud is present, the bushes should be constantly looked over and all abnormally swollen buds picked off and burnt.

Propagation.—Cuttings of the foregoing are easily rooted, and may be put in rows in some sheltered border. The lower buds should be removed to prevent suckers appearing, except in the case of Black Currants.

Root-Pruning.—Very marked improvement in the crops of various fruit trees is brought about by root-pruning. The trees marked for this attention should be dealt with before any signs of growth are evident. Try to encourage surface roots by adding fresh soil.

The Fruit-Room.—Examine the fruits frequently and remove any showing signs of decay. If this is neglected, many sound fruits coming in contact with the decayed ones would quickly become infected. The fruits must be kept safe from frost and a little fresh air admitted when the weather is fine.

The Kitchen Garden.

French Beans.—Make fortnightly sowings in 8-inch and 10-inch pots where a supply of this vegetable has to be kept up. A temperature of 55° to 60° is necessary. Red spider must be prevented, if possible, from getting a footing by frequent syringing. *Canadian Wonder* and *Osborne's Forcing* are both reliable varieties for indoor use.

Vegetable Marrows.—Seed sown now in heat will ensure a supply during March and onwards if a heated frame or pit is available. Hand fertilisation of the flowers is necessary if this early crop is to be a success.

Cauliflower.—To make a succession to the autumn-sown plants, sow now some early sort, such as *Early Erfurt*. The seedlings are very liable to damp off, and must be watered with great care. When large enough to handle, prick out into a cold frame.

Lettuces.—Both *Cos* and *Cabbage* varieties are welcomed early in spring. The young leaves are even useful some time before the plants commence to turn in. Make a sowing now in boxes and protect from slugs.

Mushrooms.—Beds showing signs of exhaustion, if not too far gone, may sometimes be revived by an application of tepid water to which some salt has been added. When damping the Mushroom-house, a spraying of the walls and pathway will be sufficient. A temperature of 55° to 60° must not be exceeded.

The Flower Garden.

Border Carnations.—The best results are undoubtedly obtained by wintering these in frames; but where plants have been put in their permanent positions they sometimes get loosened by frost, and should be replaced firmly when milder weather returns.

Bedding Geraniums.—As damp is the worst enemy of these during the winter, they had better be freed from decayed leaves and freely ventilated on all favourable occasions.

Standard Roses.—When tied to supports, it should be seen that all fastenings and stakes are in order, as gales might otherwise snap the stems. When fastenings have become tight owing to expansion of the stock, they should be retied to avoid strangulation. It is advisable to slightly shorten any straggling growths; these would in any case have to be removed later at pruning-time. By removing them there is less risk of breakage.

Fruit Under Glass.

Pot Trees.—To obtain well-coloured and ripe fruit in July and August, a number of trees should be selected and started gently in some vinery or Peach-house if an orchard-house is not available. Apples, Pears and Plums succeed admirably as pot trees. The trees potted during October and November have had full exposure outdoors, except the pots which have been plunged in leaves to prevent them being cracked by frost. The trees should be looked over for insect pests, and if any woolly aphid or blight is present, apply methylated spirit to the affected parts. The drainage of each pot must be examined. The trees may be syringed occasionally on bright days, and, when the flowers open, a thinning with scissors should take place; this greatly assists the remaining flowers to set.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockertie, N.B.

THE CULTIVATION OF SWEET CORN IN ENGLAND.

IN the modern demand for a wider range of vegetables a number that were at one time practically obsolete have been resuscitated, and have had attention from those whose duty it is to grow vegetables for home consumption. In addition, a few new kinds have also been tried, and foremost among these are the edible forms of the common Indian Corn or Maize. Unfortunately, these have not up to the present been very favourably received in this country, a fact that is perhaps due to a chain of circumstances such as few vegetables have encountered at the outset of their career.

Growers have, of course, for many years cultivated the ornamental varieties of Maize for decorative purposes, and it sufficed if seeds were sown under glass in March and grown on for planting out at the end of May or early in June. But for edible purposes the seeds must be sown earlier so that strong plants of large size are ready for planting outdoors at the period named, otherwise our summers are too short for the plants to produce a good crop of cobs. This late sowing, together with gathering the cobs at the wrong stage and improper cooking, have done much towards discouraging the pioneers in the cultivation of this vegetable.

It has already been stated that seeds must be sown early for the purpose of securing large plants by early June, and the first week in February is a good time to sow them. A hot-bed frame is an ideal place, but, failing this, recourse must be had to the warm greenhouse. A system that I adopted some years ago, when Sweet Corn was first grown as a vegetable in this country, was to fill some 3-inch pots with good rich potting soil and sow one seed in each pot, these subsequently being stood either in the hot-bed frame or on a shelf near the glass in a warm greenhouse. The young plants were not long in appearing, and growth was rapid, but care was always taken to ventilate the frame or house whenever the weather outside was at all genial; this, together with keeping the young plants near the glass, induced firm, sturdy growth, and so laid the foundation on which future success was based. In the course of three or four weeks from the time the seedlings appeared they had filled the pots with roots, and were then moved into pots 5 inches or 6 inches in diameter, the latter for preference. As Maize plants at all stages of their career are gross feeders, it is necessary that the soil used at this repotting be good; turfy loam three parts and well-decayed farmyard or stable manure one part I found answered very well, and this was made moderately firm.

After this repotting the plants were taken back to the warm frame or greenhouse, but when they had established themselves in the new pots ventilation was given more freely, the more favourable outside conditions allowing of this being done, until, by the second week in May, the plants were being given open-air treatment by day and only slight protection at night. This early sowing of the seeds, and the subsequent growing on and proper hardening of the plants without a check, is the most important item in the cultivation of Sweet Corn. Without sturdy plants 1 foot to 18 inches high, according to the variety, for planting outdoors

the first week in June, it is useless to attempt to get cobs of good quality.

During the time the plants are being raised under glass the bed outdoors must be prepared, and the earlier this is done the better. Almost any good garden soil will grow good plants, but it must be well and deeply dug, and should have at least a 3-inch-thick dressing of partially decayed manure mixed with it at the time the digging is done; if the soil can be dug from 18 inches to 2 feet deep, so much the better. If this is done early in the spring it will have become nicely settled and in good condition for planting by the time it is required. A position sheltered from strong winds should be selected if possible. The plants should be put out in rows 3 feet 6 inches to 4 feet apart, the former for dwarf-growing varieties and the latter for those of more majestic stature, and a distance of 2 feet must be allowed between the plants in the rows. When planting, care should be taken to keep the ball of soil and roots intact, as the one thing to avoid above all others is a check to the growth of the plants. If well watered at the time of planting, the plants will need but little subsequent attention, except that a mulching of short manure spread over the roots during the hot days of July and August will be of considerable benefit. Some of the leading seedsmen in this country now list several varieties that are specially suitable for our climate.

As already stated, the gathering of the cobs at the wrong time, together with improper cooking, have done much towards bringing the Sweet Corn into disfavour; indeed, unless close attention is given to these apparently trivial items, a whole season's labour will be lost. The corn or seeds ought not to be allowed to turn mealy inside before they are gathered; a good test is to press one or two with the thumb-nail, and if milky inside they are in a proper condition for gathering. Cooking is of equal importance. The cobs should be boiled in their husks for about twenty minutes to half an hour; if boiled longer, the corn becomes hard and unpalatable.

H.

A SELF-SOWN WOOD.

IT is often cited as a matter for wonder, or at least some degree of surprise, that when a wood of one kind of tree is cut down, quite other kinds of trees soon appear as seedlings. But country folk, who are familiar with the ways of woodland, know that such changes are only in the ordinary course of events. The ground under trees is full of various Nuts and seeds, brought by birds and squirrels as well as wind-blown. While it is covered with woody growth and there is but little light and sun-warmth reaching the earth, the state of things is not favourable to development, so that the seed, after lying dormant for some time, either decays or germinates feebly and throws up a weak, leggy growth that is of no account. Many seeds, after lying for some time, perish in this way, but some retain the possibility of vitality for a number of years, and meanwhile the supply is continually renewed. As soon as the wood is cut down, the conditions at the earth surface are changed. The sun warms the ground and the combined action of heat, light and moisture stimulates the seeds. The same occurs with the lower plants in copses of under-wood. These copses are usually allowed to grow

for seven years. For the last three years before cutting, when the leafy branches meet and mingle overhead, there is hardly any wild growth below. One pushes through with some difficulty, finding only the carpet of dead leaves under foot. But as soon as the copse is cut, the seed stored in the ground comes to life. By the second year there are masses of Primroses and Campions, and, in some places, a perfect turf of seedling Foxgloves, while the bulbs of the Bluebells and the creeping roots of the Wood Anemones take heart again and flower and flourish.

A small wood of ten acres adjoins my garden. Formerly it was a wood of Scotch Pine of some seventy years' growth. Under the close-growing trees the ground was bare but for a scant sprinkling of Whortleberry, Heath and Bracken at the lighter edges. Thirty-five years ago the Pines were cut and the ground left bare. Soon it became covered with Heath, Ling and short Bracken, and, on one side especially, a stronger growth of Whortleberry. Then, year by year, tree seedlings of many kinds came up in considerable quantity, so that there was not a yard of ground without one or more. This went on for some nine or ten years before the land came into my hands, and by then the seedlings were, in many places, so thick that it was impossible to get between them. From that time onwards the problem was how best to thin them, also to cut out a few paths on the easiest lines to serve the future laying out of the ground where house and garden were to be.

What is most remarkable about these few acres of seedling growth is the large number of trees and shrubs of native species that are present. The larger trees are represented by Beech, Oak, Ash, Spanish Chestnut, Lime, Birch and Scotch Fir. I believe I may say that every British conifer and evergreen is among them, except Box; for, besides the seedlings that one would expect from the original Pines, there is a spontaneous growth of Spruce, Larch, Yew and Juniper, also Holly in abundance. Ivy and Honeysuckle, both of woody growth, though hardly classed as trees, are in plenty; the latter in large quantity—in many places covering the floor of the wood with a treacherous knee-high tangle that makes walking difficult. Of the Apple tribe there are no fewer than six, namely, Mountain Ash, White Beam, wild Cherry, Crab, Whitethorn and Blackthorn. There are a few saplings of Ash and Sycamore, and though it is at the top of a dry hill, several plants of Willow, evidently from wind-blowing of the feathered seeds. There are also Hazel and Elder, Broom and Gorse. Of less common shrubs, though fairly frequent in the neighbourhood, there is one example of Alder Buckthorn (*Rhamnus Frangula*), a bush that always arrests me with a sense of interest. I cannot say why, as it is not conspicuous or specially beautiful; perhaps it is because one only comes upon it now and then, and because it is one of the woodland things that no one seems to know the name of. There is one example in a wood not far off that has assumed the shape of a tree, with a single tall trunk about five inches thick.

Those mentioned account for twenty-five of our native trees and hard-wooded shrubs, not counting Ivy and Honeysuckle. I can only think of fourteen others that are not represented. These are Elm, Wych Elm, Poplar, Field Maple, Alder, Horse Chestnut, Walnut and Hornbeam among trees; and of shrubs, Dogwood, *Viburnum Opulus* and *V. Lantana*, common Buckthorn, Spindle-tree and Privet.

GERTRUDE JEKYLL.

THE UPKEEP OF GARDEN HEDGES.

TO the owner of an established garden there is no subject that is more perplexing than the proper upkeep of the boundary hedges. These hedges are usually required for protection from strong, cold winds, and in some instances from the inroads of cattle, and nothing adds more to the attractiveness of a garden than hedges that are properly cared for. Hedges of this kind naturally fall into two sections, viz., those that are newly planted and those which have been long established.

The question of cutting back young hedges at planting-time is one that is little understood, and considerable harm has not infrequently been done through ignorance. Whitethorn should be cut back severely, but Holly, Yew, Box, Beech and Arbor-vitæ are best left alone for at least one year, and, unless growth is very active, two years may well elapse before any pruning is done. After the first year the treatment of a young Whitethorn hedge will depend to some extent on the height and width that it is desired it should attain. If a hedge only a few feet high is required, the young plants may be cut back rather severely each year, leaving from 1 foot to 18 inches of fresh growth, according to the vigour and density of the plants, until the full height is attained. Where a higher hedge is desired, from 18 inches to 2 feet may be left, always, however, bearing fully in mind the natural density or thinness of the Thorn plants. The object is to get a good base at the outset; if a hedge is allowed to run up too quickly, it is almost certain to become thin at the bottom, and it will be a difficult matter to subsequently induce it to thicken. Holly, Yew and Box, in their initial stages, will not need the top growths cut, unless, as is very unlikely, they are growing rapidly. The side shoots must be shortened; the general contour of the finished hedge must be borne in mind and worked for as far as possible. If any leading or top shoots are growing away beyond the bulk, they should be cut back, and after a few years, when the hedge is nearly high enough, it will be necessary to curtail the whole. The treatment of the top must, however, rest mainly with the condition of the hedge from year to year. If it appears to be growing too fast and not dense enough, it will be wise to cut down the top or leading growths. Arbor-vitæ and Beech need both top and sides curtailed somewhat in the young stages, as they are not naturally so dense-growing as the Holly, Yew and Box. This shortening is best done with secateurs, so that each shoot is taken out separately. Laurel, which is not a desirable plant for a garden hedge, but which is sometimes used for the purpose, particularly where a dense screen is required in a few years, must have both top and lateral growths cut back, to the same extent as advised for Whitethorns, but the work must be done with secateurs or small shears, so that each growth can be cut out separately without cutting through the leaves.

If all perennial weeds are taken from the soil before planting, little trouble will be experienced in keeping down the seedling weeds, provided they are at no time neglected. The young hedges ought to be cleared of weeds at least three times, during spring, summer and autumn, and should not, in dry weather, be experienced, a 6-inch-thick mulching of short manure on either side of the

hedge, and extending outwards for at least a foot, will prove highly beneficial.

The pruning or clipping of established hedges needs some care, and should be done at the proper season to give the best results. While some kinds, notably Beech, Whitethorn, Holly, Yew and Box, will stand cutting with shears with impunity, others, such as Arbor-vitæ and Laurel, ought to be pruned with knife or secateurs. Even Holly is best done in this way if time permits, but it would be a very tedious and expensive task where large hedges had to be dealt with. Beech hedges are best trimmed during August or September, before growth gets very hard. Whitethorn ought to be cut twice, once about the end of June and again during October. Holly and Yew are best clipped in April, though they may be successfully trimmed during September or October if desired. If, however, it is necessary to cut them back rather severely, leave the work until April. Box and Arbor-vitæ are also best cut in April. Laurel should be dealt with during August, September or October. The shape of the hedge will naturally vary with the position it is to fill. As a general rule, the base should be slightly wider than the top, and except for high hedges of great density, such as Yew, Holly and Box, a flat top is preferable, though this is more or less a matter of taste. Where the kinds named attain a considerable height, it is wise to have the top slightly ridge-shaped, to prevent snow accumulating there in any harmful quantity. During the autumn dead leaves have a habit of collecting at the bases of hedges, and if allowed to accumulate there year after year tend to kill off the basal growths.

Considerable harm is sometimes done to good hedges by the stopping of thin places with dead material. This only tends to kill more of the live growths and so enlarge the gap. Where a thin place is found, some young shoots should be stretched across it in an outward direction, so that light and air can reach them, and unless the hole is a particularly bad one, the growths will not take long to fill it. But sometimes, owing to the demise of a large branch, it is necessary to do something more, and the wisest course to adopt will be to dig out a good hole, fill in with some specially prepared soil, and plant a young bush of the same kind as the hedge. In a year or two this can be trained in keeping with the general contour of the hedge.

Recently several enquiries have been made about the cutting of Box edgings, a subject that is akin to the cutting of hedges. Happily there is no necessity for hard-and-fast rules, and most gardeners now have the Box edgings clipped with shears as they require it, the work being generally done at midsummer and again in autumn. If, however, the Box has become somewhat overgrown and it is necessary to cut it back rather severely, it should be left until early in April; new growth is quickly made at that season, and any bareness that may result from the hard cutting is quickly hidden.

T. T. S.

BOOKS.

The Garden Under Glass.*—As set forth in the introduction, the object of the author is to provide a work for the amateur, in which is couched in simple language how work should be done, lists

* "The Garden Under Glass," by William F. Rowles. Published by Grant Richards, Limited, London; price 6s. net.

of plants suitable for different purposes, and useful diagrams illustrating the structure of the greenhouse and the carrying out of many garden operations. That it covers all ground likely to be of service to the amateur is shown by the list of contents, which are divided into six parts, namely, "The Construction of Glass-houses and Frames," "Popular Greenhouse Plants," "Fruit Under Glass," "Vegetables Under Glass," "Greenhouse Work" and "Miscellanea." Some thirty pages are devoted to the building, staging and heating of the greenhouse, the fruit house, and other more rough-and-ready means of protection. The list of flowering plants is a good one, and explicit directions are given for their culture. At the same time, it would have been better if a more prominent feature was made of the fact that two or three separate houses would be required for the successful culture of the many plants referred to. In the case of *Amaryllis* (*Hippeastrum*), the fact gradually gaining ground among gardeners that the bulbs do not need repotting every year is dwelt upon. The list of greenhouse flowers in winter (page 144) is such as could by no means all be grown in a greenhouse, for it includes *Begonia Gloire de Lorraine*, *Poinsettia pulcherrima*, *Euphorbia jacquiniæflora*, *Calanthe Veitchii*, *Clivia miniata*, with *Cyclamens*, *Cinerarias*, *Primulas*, *Zonal Pelargoniums*, *Stocks*, forced *Hyacinths* and *Tulips*. The directions for growing fruit and vegetables under glass are very explicit, as also are the many cultural details, which, under the heading of "Greenhouse Work," occupies a great deal of the latter part of the book. A weak point—very evident throughout the entire work—is the slipshod way in which capital letters are used in connection with the names of plants. A marked example of this may be found on page 141, where, in a list of some twenty-five climbing plants suitable for growing under glass, the generic names are all spelt with small letters except *Asparagus* and *Ficus*. Why only these two should be so honoured cannot be imagined. Much the same may be noted on page 143, where a list of plants suitable for hanging baskets is given. Not many cultivators will be found to agree with the writer that tuberous *Begonias* do not relish root disturbance, and may be left for two or three years without breaking up, whatever this may mean. Again, referring to *Primula kewensis*, the writer says that the flowers are of a colour hitherto unknown among indoor *Primulas*. That such is not the case is evident from the fact that its parents—*Primula floribunda* and *P. verticillata*—are both greenhouse kinds and both have yellow flowers. Notwithstanding these numerous imperfections, most of which would have been avoided by more careful reading of the proofs, it is a work of considerable value to the amateur, as it goes into details so fully, and is without the fault, common to many books, of assuming that the reader knows more than he really does. One may, however, take exception to "The Cheerful Greenhouse" depicted in the coloured frontispiece, and more particularly to the assertion that "Rightly managed a greenhouse need never be duller than this"! For such a display, say, in December, it would be necessary to draw on several houses with varying temperatures.

Adventures Among Wild Flowers.*—The author refers in the first place to an early love of flowers, stimulated in his boyhood days by earning a promised three sovereigns for finding sixty

* "Adventures Among Wild Flowers," by John Trevena. Published by Edward Arnold, London; price 7s. 6d. net.

blooms of the Pasque-flower (*Anemone Pulsatilla*) on a certain spot in the chalky downs of Berkshire. The main portion of the book is devoted to a journey to the Swiss and Italian Alps, and to a description of the many charming plants to be found there. The conditions under which they thrive are fully dwelt upon, and the entire work is interspersed with light anecdotes of the many adventures which befel the author while travelling in out-of-the-way places. The misapplied use of "alpine" to many of the dwarf plants suitable for the rock garden is dwelt upon, for, as pointed out, they may come from the Himalayas, Rockies, the Cotswold Hills or Siberia, and, providing they are of small growth and suitable for growing among rocks, the term "alpine" is invariably applied to them. The halo that, in popular opinion, surrounds the Edelweiss forms the subject of a note, it being pointed out that in ordinary garden soil it will flourish as readily as a Double Daisy. In the search for flowers in the elevated regions of Switzerland and Italy, the reader is carried step by step through the different districts, and the ever-varying phases of plant-life fully explained. In many cases comparisons are drawn between the behaviour of the plant in a state of Nature and in the writer's home in the Dartmoor district. The black-and-white illustrations taken from photographs are charming, and, for the most part, they depict a plant or colony of plants amid congenial surroundings. One thing that ought not to occur in such an otherwise carefully written book is that mistakes in the use of capital letters continually crop up. Though there are many, two or three illustrations will suffice. On page 107 *Rhododendrons* and *Primulas* are mentioned two or three times over, each time commencing with a small letter. Then, on page 152, *Erigeron aurantiacus* has the specific name beginning with a capital letter. On page 258 some of the species of *Sedum* are honoured with capita's, while on page 263 the genus itself is spelt with a small letter. For all this, it is a book which can be thoroughly recommended to the plant-lover who is anxious to learn something of the conditions under which the occupants of his little rock garden grow wild. It is very probable that the author would at the present time be of a different opinion concerning a part of one paragraph which occurs in the book, and which we cannot refrain from quoting: "The Alps are to Italy what the Channel is to England, a natural protection against the army of invasion. Yet Italy has allowed her line of defence to be pierced in three places, and despite certain insular croakings she is never likely to suffer for it; indeed, if that army did threaten, we can easily imagine the Italian commander-in-chief exercising all his powers of strategy to lure the enemy into the St. Gothard or Mont Cenis, while England, with an example now thirty years old before her, still declines to complete the Channel tunnel, which, with her coastline strongly fortified and the friendship of France assured, would render her secure against invasion and diminish by one-half her Naval Estimates. As a patriot I hope that tunnel will be built in time."

Transpiration and the Ascent of Sap in Plants.*—This is a work of a highly scientific nature, illustrating numerous experiments on the transpiration and the ascent of sap in plants carried out by the author and Dr. J. Joly in

* "Transpiration and the Ascent of Sap in Plants," by Henry H. Dixon, Sc.D., F.R.S. Macmillan and Co., Limited, St. Martin Street, London. price 5s. net

collaboration, assisted by others. As to the subject-matter of the work, we cannot do better than quote an extract from the author's preface: "In the present monograph an account is given of a physical explanation of the rise of water in trees. This theory rests on a knowledge of a property of liquids, which, though discovered in the middle of the last century, was little recognised and seldom referred to in physical literature. It now appears that a full appreciation of this property is essential for the realisation of the manner in which water is raised in plants, and of the meaning of the structure of trees as a mechanism for lifting water." The series of experiments conducted by the author to support his theory is very exhaustive, and of great interest to the more advanced plant scientists. It is in every respect a well-produced work, and should prove of considerable value to those who have mastered the more rudimentary portions of the science of botany.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

COLOUR ASSOCIATION (Interested).—Our correspondent enquires, "What colours could be used in a long border of various shades of pink *Antirrhinums* as dot plants?" and the immediate answer is, it is very much a question of taste. Candidly, we do not care for "dot" planting. The effect in a border is usually poor and weak, and contrast grouping or grouping for harmony is more pleasing or effective. With pink of all shades, yellow, cream, white and rose pink invariably agree; strong or intense blue, as seen in *Salvia patens*, usually the reverse. If blue is used, it should be of the softest shades, palest lavender or something akin usually found in Sweet Peas, which would probably be too tall for your purpose. For most of the first named you might encroach even more deeply upon the Snapdragon family itself with good effect, in plants of even weight and floriferousness. For example, supposing you were employing dwarf *Antirrhinums* in the main, a bold outcrop group of yellow or white formed by one of taller growth, say, of the medium or tall section, would be rather striking. Effective and easily grown plants to remember are *Statice Bonduellii* (pale yellow), *Helichrysums* Silver Queen, Golden Globe and Pink Beauty, with perhaps a *Fuchsia* like Ballet Girl, whose big white corolla is more conspicuous than the scarlet sepals. In foliage plants, white and silvery leaved ones, as *Cincaria maritima* and *Centaurea candidissima*; in green, Summer Cypress or *Kochia*; in variegated, *Dactylis glomerata* elegantissima and *Holcus lanatus* variegata should be kept in mind. If possible, crescent-

shaped bays, each separated from the other by at least 4 feet of an intervening mass of the Snapdragon, might be arranged in front of the border, and planted with white, cream and pale yellow Tufted Pansies or like shades in tuberous *Begonias* would be very effective. If this were done, we should be inclined to abolish the "dot" groups entirely, and instead arrange a double row of white or pale yellow Snapdragons at the back for effect. These are, of course, suggestions, and without knowledge of the surroundings some may be impracticable. At the same time they might constitute a sort of finger post. We do not know of a cheap book likely to be of the least service to you, but "Colour in the Flower Garden," by Miss Jekyll, published at this office, post free 12s. 11d., would be very useful.

THE GREENHOUSE.

TREATMENT OF *CŒLOGYNE CRISTATA* (Joe).—

This is the name of the Orchid of which you sent a specimen. It, as a rule, blooms in February and March, and the spikes of flowers with their conspicuous orange lip are always much admired. The general directions for its successful culture are as follow: In the first place, it needs the temperature of a warm greenhouse or intermediate house, where, as a rule, it blooms during February and March. About a month after the flowers are over is a good time to repot it if necessary. From what you say, it is most probable that yours needs repotting, which should be carried out at the time stated above. It must be borne in mind that the *Cœlogyne* is a shallow-rooting subject; hence for its successful culture pans are much preferable to pots. These pans should be quite clean and half filled with broken crocks, over which must be placed a layer of Sphagnum Moss. A suitable compost may be made up of three parts fibrous peat and the remaining part of Sphagnum Moss cut up into short lengths, a dash of loam, and some fine broken crocks with a little silver sand. Such a mixture will keep fresh and sweet for a long time, as when in good condition the plants will not need repotting every year. After being potted they must be shaded from the sun till thoroughly established, after which the shading may be lessened, and towards the end of the summer the plants will be benefited by exposure to full sunshine in order that the bulbs are thoroughly ripened. When growing freely they need a good supply of water at the roots and a daily syringing overhead. Soon after growth is completed—that is to say, when summer is well advanced—the flower-spikes commence to show, but they make slow progress. As soon as they are seen, the plants must not be syringed or watered overhead, as if moisture collects around them they are apt to damp off. At this period the plants will require less water, but at no time must they be kept dry enough to cause the pseudo-bulbs to shrivel. As the flowers develop, more water will, of course, be needed, but not to the same extent as when the plants are growing freely. It is quite possible, when you turn your plant out of the pan in which it is growing, that it will naturally divide into several pieces. If such is the case, they may be returned to the pan and distributed over it, not bunched up in the centre. In this way they all have room to grow. Care must be taken to place the growing shoot pointing towards the centre of the pan, and thus ensure a shapely specimen. If you desire to increase your stock, any smaller pieces may be put singly into small pans, or even pots, and treated as above recommended.

ROCK GARDEN.

MOSSY SAXIFRAGES BROWN IN CENTRE (Grey Court).—The only thing to do in the circumstances is to lift and replant the portions of the clump which remain green, the "bare portion in the centre" being doubtless dead and beyond aid. This dying off in the centre is not an infrequent result of an early excess of growth, which virtually lifts the central portion of the clump out of touch with the soil. It is more frequent, too, in the case of the stronger-growing sorts than with the dense carpeters of the race, and in particular where the plants are not either well watered in times of drought or heavily mulched with soil. All these Saxifrages root afresh, when opportunity is afforded them, from the immediate base of the rosettes of leaves; hence either replanting or heavy mulching is needed to sustain vigour in the old plants. In your case replanting the livelier parts of the plants will be the best, and in so doing arrange three or four rosettes, i.e., single growths, on a level, and so insert them that their bases are firmly set in the soil. By arranging a dozen or more examples of the size named over an area of 2 feet, a new clump with all the vigour and freshness of youth will presently result. Endeavour, of course, should be made to get root fibres to each, the old stems to be well buried in the soil. In dealing with the smallest kinds, allow double the number of rosettes to each tuft. The work may be done now or in February or March next.

ROSE GARDEN.

SWEET BRIARS PLANTED IN NOVEMBER (Rustic).—There is no need to prune the Sweet Briars the first season after planting, excepting just to remove the extreme ends in March. The second year and subsequent years, in order to keep the hedge well furnished at the base, prune hard back one or two of the oldest growths. When the Briars attain the desired height, they may then be pruned back as you wish. These remarks apply to the common Sweet Briar, also the Penzance hybrids.

THE GARDEN.

No. 2253.—VOL. LXXIX.

JANUARY 23, 1915.

NOTES OF THE WEEK.

The City of London Rose Society.—This society, which is as yet in its youth, continues to make good headway, and the committee have decided to hold their summer show on Thursday, June 24, at Cannon Street Hotel. The Lord Mayor, the Right Hon. Sir Charles Johnston, has kindly consented to act as president for this year, and has promised to open the show on the date named. An excellent schedule is being prepared, and full particulars of membership can be obtained from the hon. secretary, Mr. A. E. Protheroe, 67 & 68, Cheapside, London, E.C.

Rosemary and Cut Flowers.—Those who have a good-sized Rosemary bush in their gardens have also excellent material for using with nearly all kinds of cut flowers that are obtainable just now. A few long sprays cut and placed carelessly in a vase with Carnations is as pleasing and fragrant a combination as one could wish for. Shoots of Rosemary and Winter Jasmine are also very effective, both by day and under artificial light. A large Rosemary bush usually needs a little cutting back, and it may now be safely denuded of too venturesome growths for the purpose named.

Trollius chinensis.—This is one of the new varieties of Trollius (Globe Flower) from China, and is distinguished by its rather tall habit, and more especially by the length of its petals, or petaloid stamens as they are frequently called. These stand up in a circle round the stamens, are a great deal longer than those of any other variety, and give the flowers a very characteristic look. It can be raised from seed, but a word of warning is necessary for those who have never sown Trollius seed. If it is kept for any length of time after it is gathered, germination will not take place for a year or even longer.

Romneya Coulteri.—There is a very fine example of this magnificent perennial in the gardens of Acton Burnell Hall, near Shrewsbury. No plant could be more vigorous and healthy. The head-gardener attributes this to his placing large, flat stones over the roots when it was planted. He has advised this course in several cases, and in each one the report has come back, he said, that his "tip" had been adopted with the best results. We have often heard of the value of stones being placed over or among roots, and now it seems that *R. Coulteri* must be added to the list of plants which benefit by this treatment. The stones at Acton Burnell are entirely hidden below the soil.

Godetia Double Rose.—Those who appreciate good annual flowers for cutting should certainly order seeds of the Godetia named Double Rose. It is of quite a different type to the older dwarf varieties, as it makes shoots 2 feet or more in length, these being studded from near the base to their tips with dainty rose pink flowers that never fail to elicit praise from visitors. It is a charming plant in the garden, but is even more beautiful when sprays are cut and placed in

preferably composed of good loam two parts, leaf-soil or peat one part, and silver sand one part. The surface ought to be made quite level and the seeds scattered evenly and thinly over it. A little silver sand is sufficient covering, but each pan or box ought to be covered with a piece of glass until germination has taken place. A temperature of 55° to 60° is desirable to raise these plants successfully from seeds, though we have seen good results with 10° less.

Four Good Dry-Wall Plants.—In dry-wall gardening many delightful surprises await the enthusiast. This particularly applies in the way individual plants adapt themselves to the wall face and the form they eventually assume. The illustration affords an instance in showing the way *Arenaria balearica* ramifies in all directions, forming a complete carpet of green stems, bejewelled with white, starry flowers. The lavender blue of *Aubrietia græca* presses close up to it from the lower courses, while higher up it forms a continuous link with the cobalt blue of *Phlox subulata* Seraph. On either side appear small tufts of the Mossy *Saxifraga cæspitosa*. All four are typical, free-growing rock plants that succeed in any well-drained garden soil and give generously of their flowers during May. The *Saxifraga* forms immense cushions of the liveliest green, and its winter aspect is delightful, while in May it becomes a sheet of creamy white.

Outdoor Flowers in Midwinter.—When looking round the garden on Sunday last, the 17th inst., we were reminded that Nature is already awakening from her winter slumber. The following list of plants in bloom, jotted down at random, may be of interest: *Galanthus Elwesii*, a beautiful large Snowdrop; the Winter Aconite, with its bright yellow, Buttercup-like flower studding a ruff of deep green; *Iris stylosa*, as delicately fragrant as its azure flowers are beautiful; Winter Jasmine, with vivid yellow blooms, the wonderful

PORTION OF A DRY WALL WITH FOUR USEFUL PLANTS IN FLOWER.

sheen of which is only revealed when they are kissed by the winter sun; Christmas Roses; the Japanese Witch Hazel, *Hamamelis mollis*, with its long, crinkled yellow petals; the Winter Sweet, *Chimonanthus fragrans*, so delightful for cutting; and Wallflower Yellow Phoenix. It would add considerably to the interest of gardens during the winter months were more attention given to such plants as those named. Not one is really difficult to grow, and most of them provide charming cut flowers for the house.

Gloxinias and Tuberous Begonias from Seed.—We would remind those who are desirous of raising these plants from seeds that during the next week or two is the best time of the year for sowing. As the seeds are very small, the well-drained pans or boxes must be filled with finely sifted soil,

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Planting Crinum Powellii.—I have found the best way is to plant very deeply, of course arranging for plant food to be beneath the bulb; but what is also important is to plant the bulb up to its neck in a concave pit; then, as the plant forms a neck above the ground, gradually during the summer to keep filling the pit until it gets to the level of the surrounding soil.—W. D. P.

Soaking Daffodil Bulbs in Water.—Mr. Jacob, on page 4, issue January 2, throws doubt on the efficacy of immersion in water of bulbs attacked by merodon grubs. He says he has not tried it. I have. I cannot too strongly recommend it being done. Fancy cutting open a bulb that has cost many sovereigns when immersion will bring out the "beast" if he is there!—C. LEMESLE ADAMS.

Helleborus niger altifolius.—Many times I have written in praise of this Christmas Rose, and am pleased you recommend it so strongly on page 1, issue January 2. The finest-grown plants of this variety I have seen are in the gardens at Corhampton House, Bishop's Waltham, Hants, the residence of W. Campbell Wyndham Long, Esq. Mr. Cawte, the gardener, manages to have huge quantities of flower early in December

be best for purposes of judging, but it quickly becomes tedious and tiresome for table decoration. In an effort to escape from it, late one autumn, I decided to do a dish of Sweet Peas for my table, and it was hailed with delight. My friends dived their noses into it and exclaimed, "How delicious!" (Folks do not desire to bury their faces in a bunch of bristles.) I do not say, however, that this "is a better way to arrange flowers, but only suggest that "variety is charming."—ANNE AMATEUR.

How to Flower Banksian Roses.—Much that is good has been written on this subject in THE GARDEN of late, and there appears to be little more to say on the subject. I do not remember one writer who has distinguished between the two varieties. Whereas the yellow form will give numerous blooms under proper conditions, it is seldom that a plant of the white form is met with that has more than a sprinkling of blooms. Naturally, it is not so free as the yellow; indeed, it is seldom met with at all. Perhaps a southern aspect is the best for the yellow variety, but on an east or even a west wall it flourishes when the growth is not too thick. A wall not less than 20 feet high suits it admirably, where the growth has plenty of space to develop and eventually becomes thoroughly matured. So many persons consider that when a Rose tree is once planted it requires no more attention. This is a mistake, as the Banksian variety revels in being well supported with moisture

of leaf-mould, no peat. Take up roots end of March, cut off all long ends (which if left untrimmed cause crowns to rot) and dibble the slices in lines." This is not a verbatim copy from the book (which I do not possess, to my sorrow), but the note I made at the time. From Sir Herbert's letter in January 9 issue it appears that the same practice is successfully followed by another Scottish gardener. May it not be that the different results obtained by such acknowledged experts as Sir Herbert Maxwell and Mr. Jenkins are due to differences in soil and climate? Both agree as to deep cultivation, but while Sir Herbert says (in "Scottish Gardens") stiff soil, plenty of leaf-mould and no peat, Mr. Jenkins advocates sandy loam with perfect drainage. Here, with a choice of both soils and a cold, damp climate, I intend trying both methods, and only wish some kind friend would supply me with a "dozen clumps of Helleborus niger maximus" for the purpose!—WALTER DE H. BIRCH, *Walton-le-Dale, Lancashire.*

A Hedge of Sorts.—Here is a list for "Anne Amateur," who appeals for suggestions on page 14, issue January 9. Will she listen to the words of wisdom of one who has gardened for so many years that she is hardly any longer an amateur? If Laurel *must* be used, thief as it is, robbing the ground for delicate shrubs, let it be the long-leaved, pointed sort, which is not ungraceful if put where it may grow tall and loose-branched and flowering. One of these Laurels in full flower is a thing of beauty; but pruned and kept in bounds—no! (1) *Amelanchier canadensis*, pale pink leaves in spring, flame in the autumn, and delicate sprays of white flowers early. (2) *Prunus Pissardii*, purple-leaved and sweet white blooms in very early spring, may be cut and brought indoors in bud, and the more you cut, the more flowers next year. (3) *Forsythia suspensa*, in February; also its yellow flowers will open indoors. Prune after flowering to get long sprays for next year. (4) *Choisya ternata*, quite hardy in Dorset, flowering twice. (5) The most brilliant-fruited Crab is John Downie, and you may boil its fruits in sugar for dessert. (6) The most beautiful-flowered Crab is *Pyrus Malus floribunda* (bring in its sprays in bud). (7) *Cotoneaster frigida*, and (8) *Pyrus Aria* for brilliant red fruits in autumn; these are little light trees. (9) and (10) *Hamamelis arborea* and *H. mollis* flower early in February. (11) and (12) *Berberis stenophylla* and *B. Drummondii*, lovely orange and yellow flowers. If not too late, do not put *only* Hybrid Sweet Briars on the posts—they flower, and are gone. Jersey Beauty flowers later and long; sweet, single, ivory. American Pillar is glorious. René André is delicious and flowers twice; salmon pink. Alberic Barbier also flowers twice, and is lemon white.—LADY OF THE FLOWERS.

A Free-Flowering Liliun auratum.—The enclosed photographs may be of interest to you. One shows three spikes of bloom from one bulb of *Lilium auratum* flowering in my garden here last September. There were in all forty-one blooms on the three spikes. It had no special care, and the bulb was purchased from a local nurseryman for ninepence. The other photograph shows the result of a bulb planted about a yard away, which had one spike of bloom only, but larger individual flowers.—ARTHUR H. LYNE, *Silver Hoor, Cliftonville, Dorking.* [Unfortunately, the photographs sent by our correspondent were not suitable for reproduction, but one showed three very fine flower-spikes.—ED.]

A DISH OF SWEET PEAS ARRANGED FOR EFFECT, AND TO PROVIDE A CHANGE FROM TALL DESIGNS.

annually by the aid of a cold frame only. In fact, he grows the roots in the frames all the year round, encouraging a free growth directly the blossoms have faded in February. By this means he builds up plants with stout crowns thoroughly matured early in the year, and which never fail to give the best results.—E. M.

Long-Stemmed Flowers.—I see one of your correspondents has on page 22, issue January 9, at last ventured on a gentle protest against the overlong stems of flowers, which seem to be the delight of professional florists. The aim of the average exhibitor appears to be to approach as closely as he can to the arrangement of bunches of bristles in a brush. This may (?), perhaps,

at the roots during dry weather, especially if that be in June or July, after the flowering season is past. It is at that period when aid in establishing a satisfactory growth is of value, giving to the foliage that glossy tinge which denotes perfect health and a corresponding flower crop later.—E. M.

Transplanting Christmas Roses.—There seems to be considerable divergence of opinion on this subject (see page 15, issue January 9). About six years ago I made the following extract from "Scottish Gardens," by Sir Herbert Maxwell, whose interesting articles on "Hardy Lilies" you are now publishing: "*Helleborus niger maximus*.—Stiff soil very deeply dug, plenty

Daffodils for the Garden.—With reference to the remarks made by "J. R." under the heading "The Ideal Catalogue" in your issue of January 9, page 22, I agree with him that there is need for more information from enlightened quarters as regards varieties of medium price which are eminently suitable for garden decoration on account of their strong constitution as well as for the exhibition table. Several varieties which are recommended in trade catalogues and are seen at nearly every show in the British Isles are more or less worthless as garden varieties. The first variety which I wish to mention is King Alfred, this being in the first rank as a show flower, but, alas! in most parts of England at least, it is an exceedingly bad doer, and until its price comes down to 2s. 6d. a dozen or so it is not worth buying except for those who must have it for the exhibition table. Where it does well it is practically the giant of its tribe, but in most localities it is so badly affected with leaf stripe that it is a poor weakling. When it has reached a moderately low price it will be worth buying a dozen bulbs every year by those who wish to compete, say, in a mixed class of twelve or twenty-four varieties, as it is most telling as a big back-row flower. Another variety mentioned by "J. R." at the beginning of his letter, which is equally prominent on the show board and which in my garden in Middlesex is also a poor doer, is Homespun, although I must say it is nothing like so bad as King Alfred and does not suffer from leaf stripe, but it is not sufficiently robust in growth to take its place among the good garden varieties. Its place on the show board is also more easily filled than that of King Alfred. There are several newer varieties of yellow incomparabilis which easily eclipse it, and which, when they become more reasonable in price, will be in the gardens of most exhibitors. At the end of my letter I give a short list of varieties which can be bought at present for ros. or less, and which I have tried here for the last two years at least and found satisfactory for any purpose. Those mentioned by "J. R." above the price stated, which come up to my standard from all points of view, are Loveliness, Great Warley and Lord Kitchener, and I might add another of my own stock, namely, Lowdham Beauty. All four are good growers, the three last mentioned specially so. My list of good strong growers within the price stated suitable for exhibition or the garden is as follows: Yellow trumpets—Lord Roberts, Mrs. H. J. Veitch, Van Waveren's Giant, Monarch and Glory of Leiden. White trumpets—Mme. de Graaff, Mrs. Robert Sydenham and Mrs. Betteridge. Bicolor trumpets—Mme. Plemp, Weardale Perfection, Glory of Noordwijk and Duke of Bedford. Yellow incomparabilises—Noble, Solfatare and Marigold. Bicolor incomparabilises—Lady Margaret Boscawen, Whitewell, Lucifer and Orangeman. Yellow Barrii—Castile, Cœur de Lion and Glitter. Bicolor Barrii—Royal Star, Sunrise, Incognita and Southern Star. Leedsii—White Queen, Diana, Evangeline and Maggie May. Poeticus—Horace, Cassandra and Virgil. Double—Inglescombe Phoenix, Primrose Phoenix, Argent, Plenipo and Dubloon. I have mentioned the six divisions which I grow, and although there are five more in the Royal Horticultural Society's Classification, the above are the ones principally grown. I do not pretend to be one of the "enlightened," and write this letter entirely in the hope that someone much better able may come to the rescue and help—A SMALL AMATEUR.

SOME HARDY LILIES.—IV.

SUB-GENUS ARCHELIRION.

(Continued from page 28.)

Lilium Henryi, introduced from Central China towards the close of last century by the intrepid collector whose name it bears, Dr. Augustine Henry, this fine Lily has already responded to cultivation by attaining a stature far exceeding that of the wild plants and by producing its gay orange flowers in greater profusion. The blossoms resemble those of *L. speciosum* in shape and size, but are of a rich golden hue, and open in late summer. It is a splendid acquisition, and its requirements are few and simple. I have seen it growing luxuriantly in gardens where little intelligence had been applied to the management of Lilies in general. Its chief peculiarity is that the long stems, sometimes reaching to 7 feet or 8 feet, cannot support themselves, wherefore the bulbs should be planted a foot deep among shrubs whereon the sprawling stems may recline. It is a lime-lover, but does not insist upon that ingredient if it has well-drained loam, a liberal supply of water in summer and, when thoroughly established, a good mulch of well-decayed farmyard manure.

L. speciosum, formerly known as *L. lancifolium*, is perhaps better known to British gardeners as a pot plant than as a permanent open-air dweller; but there is only one drawback to its use in the borders, namely, that, although the earliest of all hardy Lilies to show above ground in spring, it is one of the latest to flower. Hence in cold or sunless districts it is apt to be caught by autumn frosts. The beauty, however, of the many varieties entitles it to a position where it may receive all the sunshine that is to be had in regions where clouds prevail. There are two sources of supply for the bulbs of this Lily—its native Japan and the Dutch nurseries. The Japanese bulbs produce the finer flowers; but, as their roots are trimmed off for export and as a large proportion of the bulbs are diseased, special precaution is necessary before they can be established in the open. "Those," says Mr. Grove, "who wish to grow the Japanese sorts should pot the bulbs for the first season, cutting off all the flower-buds that may form, and planting out any that are in good condition after the first season's growth. This may be a trial of patience for some, but it is the best way in the end." Dutch-grown bulbs of *L. speciosum* generally arrive in this country in pretty good condition; but it is worth the extra trouble to attain success with the finer Japanese varieties, of which the pure white Krætzleri, the glowing rubrum magnificum and the rose-coloured Melpomene are the pick. The cultural requirements of *L. speciosum* are the same as those of *L. auratum*, save that, owing to its habit of late flowering, it should be given a sunnier position. The stem

roots will take as much nourishment from rich mulching as can be afforded them, with marked effect upon the quality of blossom.

L. tigrinum.—If the Tiger Lily were a rare species, or if it required elaborate preparation of soil and other conditions of cultivation, it would be prized as one of the most delightful flowers in British gardens. Luckily, it is to be reckoned among the easiest of Lilies to obtain and to grow, although it does not always receive the attention it deserves and requires, if it is to be enjoyed at its best. The type is a fine thing, but the varieties splendens, with stems of shining black, and Fortunei, with lofty wands clad with wool, are finer still. The bulbs should be planted at least 6 inches deep (those of Fortunei 10 inches or 12 inches) in good loam with an admixture

LILIAM DAVURICUM LUTEUM, A CLEAR YELLOW VARIETY WITH PROMINENT DARK SPOTS. (See page 40.)

of pulverised peat and sand, without a suspicion of lime or chalk, and in full sunshine. There is a double form of this Lily, but if I had my heel on the last bulb of it I would crush it (unless I had it cooked for the table, as the Chinese use it), for in the double flower is destroyed that union of splendid colour and perfect form which distinguishes the Lily genus among all herbs of the field. The propagation of all varieties of the Tiger Lily is extremely simple, by means of the bulbils which form in the axils of the stem leaves. If these are set out in lines in a nursery bed, flowering bulbs will be the result in three or four years. Cultivated in Japan as an article of food, the bulbs of this Lily (and most other Asiatic species) have a peculiar attraction for rats and mice; wherefore deep planting is expedient and a stony soil is no slight advantage.

SUB-GENUS ISOLIRION.

Lilium bulbiferum.—One is accustomed to hear this Lily slightly spoken of as a coarse and uninteresting species. If I cannot share this view it is because, many years ago, I brought home a Lily from an altitude of between 6,000 feet and 7,000 feet in the Valtelline, which bore flowers of a splendid flame colour. I believe this to have been a fine variety of this species. It is a plant there is no excuse for losing, seeing that it bears axillary bulbils as liberally as the Tiger Lily; but lost it I have, during a

long series of summers squandered in the House of Commons. There is no mystery in the cultivation of this species; what satisfies the Orange Lily will leave the bulbiferous one nothing to complain of.

L. concolor, a desirable little Lily of Chinese origin, bearing, on stems 12 inches to 18 inches high, three or four crimson flowers. It is said to be easily grown if planted 5 inches deep in sandy soil, not allowed to suffer from drought in the growing season or from want of rapid drainage when at rest, but I have no experience of it, save as seen in the borders of a friend.

L. croceum.—The true Orange Lily is not always to be had when ordered from a nurseryman, though some very handsome hybrid or variety may very likely be supplied, with flowers more or less stained with sanguine hue. The type, however, brought to this country centuries ago from the Mediterranean, is commonly to be found in the garden plots of cottages and farm-

spirally, ending curiously in a flat top, on which the brown flower-buds appear in May. The fine varieties of *L. davuricum* require general treatment like that prescribed for the Orange Lily, but they are less able to withstand winter wet; wherefore, unless a place can be given them where water runs quickly away, the pits to receive them should be dug deep enough to admit an inverted flower-pot being set beneath each bulb, with a covering of 4 inches or 5 inches of soil over the bulbs. In June of the present year there was a splendid display of *L. davuricum erectum* on a small island of the river Itchen, on which Mrs. Trimmer had set about a hundred bulbs. They have grown strong and multiplied, and the blaze of colour could be seen half a mile away.

L. elegans (syn. *thunbergianum*), a dwarf Lily from Japan, differing from the European *L. bulbiferum* and *L. davuricum* in that it is a stem-rooting species, whereas the others root only from the base of the bulb. It is the pro-

colour of the flowers varies in different plants, but is most commonly bright orange with purple spots. Each segment of the flower is set on a narrow stalk, giving the erect blossom a very delicate grace. It requires to be planted 5 inches or 6 inches deep in well-drained loam without lime.

HERBERT MAXWELL.

(To be continued.)

SOME WINTER-FLOWERING HEATHS.

ALTHOUGH the Heath garden is interesting at every season of the year, it is during the dull days of winter that we most appreciate the dainty little flowers of this moorland family.

Of no other race of hardy shrubby plants can it be said that we have representatives in flower during every month in the year; hence it is not surprising to find that hardy Heath is rapidly gaining in favour. Articles on their cultivation have appeared in these columns from time to time, and it is not necessary now to go into details of what, after all, is a very simple gardening operation. Given thoroughly drained and, therefore, moderately warm soil that is free from lime and contains a good proportion of humus, most of the hardy Heaths will grow and flower well with very little attention.

The best of all the Winter Heaths, or at least the one that is most appreciated, owing to its early flowering, is *Erica mediterranea hybrida*. This rarely exceeds 1 foot in height, and often only reaches a modest 6 inches, making a neat tuft of green branching stems and foliage that from early December until well into February are smothered with bright rose pink flowers. It is quite hardy and appears to do well nearly anywhere. It is really difficult to understand why this Heath is not more extensively grown, as for some years past large beds of it at Kew have provided valuable object-lessons in winter colour effects for all who wish to learn. The next Winter Heath to be mentioned is *E. carnea*. This does

not usually reach the zenith of its beauty until February is well advanced, but for some time previously the plants are full of greenish purple flower-buds that have apparently been waiting for the late winter sunshine, with its increasing power, to develop fully the carmine red colour of its myriads of flowers. It rarely exceeds 6 inches in height, and the sight of a large colony clothing a rugged, sun-kissed bank in February is not easily obliterated from one's memory. There is a white-flowered form of it named *E. carnea alba*, but the blossoms are only of a dirty white tint, and it is not a plant to be compared with the type or the white Heather of autumn.

The other hardy Heath that calls for mention now is the Portuguese Heath, *E. lusitanica* or *codonodes*. This makes a tall, erect bush 3 feet to 4 feet high, and during the latter part of January and onwards through February is usually covered with its whitish, pink-tinged flowers. *E. Veitchii*, a hybrid raised by crossing the Portuguese Heath with *E. arborea*, flowers in late winter and early spring.

ERICA CARNEA MASSED ON A ROCKY BANK. THIS IS A CHARMING HEATH IN WINTER AND EARLY SPRING.

houses, especially in the North of Ireland, where its presence indicates the religious and political faith of the householder. It is a splendid Lily, though use has blunted our appreciation of the fine gold which it displays early in July. Plant the bulbs in a sunny place about four inches deep in loam inclining to stiffness, and leave them alone, except for an occasional dressing of well-rotted manure. It flowers in July.

L. davuricum, a Siberian species, has become so mixed up with the garden varieties known as *L. umbellatum* that the original wild form is seldom seen. Several of these varieties are well worth growing, probably none more so than the kind ticketed "incomparabile," with flowers of intense blood colour, and the gay *L. davuricum luteum*, clear yellow, beautifully set with dark spots. Nor are the flowers the only attraction offered by the umbellate Lily. It makes its early appearance above ground in most delightful fashion, sending up a stout column densely clothed with bronze-coloured leaves set

genitor of a great number of varieties, much more attractive than the type. I must confess that, although I have grown several of these, I have quite lost count of the nomenclature, and am fain to resort to Mr. Grove's list of those which he considers best, namely, *Horsmanii*, dark crimson; *Alice Wilson*, yellow; *venustum*, apricot; and *Wilsonii*, late-flowering. These Lilies require all the sunshine they can have in this country, provided their roots are screened by some lowly growth. The bulbs should be planted 9 inches deep in very sandy soil. In the Kew List, *L. Batemani* and *L. Wallacei* are described as varieties of *L. elegans*; but Mr. Grove takes exception to this arrangement, pointing out that the bulb of each is quite different from that of *L. elegans*. ("Lilies," pages 52 and 53).

L. philadelphicum is a gaily-coloured little American Lily, not nearly so well known in British gardens as it deserves to be. It bears umbels of three or four flowers on stems 18 inches to 2 feet high, and likes a sunny situation. The

ROSE-GROWING IN TOWN GARDENS.

Protection from Frost.—It is now many years since a severe winter has been experienced in this country, and consequently those who have neglected to protect their Roses during the coldest months have seldom had to pay the full penalty of their omission. It is quite usual, however, for a certain proportion of the trees to fail even after a mild winter, and as the damage done by frost is often undetected until the spring is well advanced, late planting, with risk of another failure, is the only means of filling the gaps in one's beds. To avoid this it is certainly worth while to take a little extra trouble before severe weather sets in. With bush Roses the only precaution that need be taken is to earth them up, that is, to draw up the surrounding soil so as to cover 2 inches or 3 inches of the basal shoots of each plant and form a small mound of earth about the crown. Even if all growth above ground is then frosted, there will still be sufficient of the plant left alive in the spring to give a good result. With standard trees there is more difficulty. The protection usually recommended is to place dried Bracken fronds in the heads of the trees, taking care to cover the points at which they were budded. In towns Bracken is not often obtainable, but straw is quite as good for the purpose, the covers used for packing wine bottles (when unfastened at the top) being just what is required, and with a little manipulation one such cover may easily be made to protect all the essential parts of a tree. Brown paper might answer almost equally as well in the dry weather, but the objection to it is that it becomes sodden, unless first greased, and one does not want to keep renewing the covering when once it has been placed in position. Cold winds, and especially draughts (as may be caused by a hole in a fence, for instance), are much more likely to damage the plants than are still frosts. The coldest winds reaching this country are from the north and east; consequently it is of great advantage to have the Rose-beds in such a position that they are sheltered from these quarters. The labels usually attached to Rose trees soon become illegible, and no time should be lost in recording the names in a more permanent manner. As I have suggested in a previous article, this is easily done by noting in a book the kinds planted in each bed in their correct order, or by making a rough plan of the beds showing the Roses in their positions. During the wet and windy weather of the last few weeks, those bushes with large heads have been so blown about as to cause a "collar" round the stem, and this is frequently filled with water. The soil must first be loosened and then made firm again.

P. L. GODDARD.

CHRYSANTHEMUMS THAT LAST WELL IN SCOTLAND.

AT this season, when the bulk of Chrysanthemums are propagated, it may be of some service to those who grow the Autumn Queen for conservatory or room adornment and for cut-flower purposes to have a few hints as to the varieties that remain in good condition for a fairly long period. I have kept notes of these in previous years and very carefully this season.

Big-Bloom Varieties.—William Turner, purest white, and when well grown one of the very finest varieties in cultivation. As a rule, second natural

Mrs. W. T. Smith is not unlike Mrs. A. T. Miller, but stands about double the time and has much better foliage. A beauty. Good flowers from either buds. Rose Queen stands well, notwithstanding its rather flimsy florets. Either first or second crown buds and good cultivation. One or two "old stagers" that are still well worth a place keep fresh for a long time. These include Mme. G. Henri (white), Lady Esther Smith (incurved white), Exmouth Rival (brilliant crimson), Buttercup (incurved), Embleme Poitevine (incurved yellow) and Edith Jameson (lovely pink).

Decorative Varieties.—Black Prince, David Ingamells (probably the longest laster of the lot), Freda Bedford, Market Red, Niveus, W. Duckham and Mrs. J. Ritson.

A BEAUTIFUL HARDY CLIMBER, POLYGONUM BALDSCHUANICUM.

crowns give the best results. Mary Poulton, a lovely pale pink of refined form and a fairly easy variety to manage. Second crown buds are best. Mrs. L. Thorn is still one of our finest yellow Chrysanthemums, and a dwarf, healthy grower. Second crown buds are best. Mrs. R. Luxford, a bright reddish crimson, but shows the yellow reverse, especially when first opening. Of excellent habit. Second crown buds are best. Mrs. E. A. Tickle, a really good pink, something like the old Mrs. G. Mileham, but larger. Good on either bud, but seconds are more refined and purer in colour. Fred Green is of a lasting wine red colour and of beautiful shape. It has fine foliage and fairly dwarf habit. First crown buds are desirable. His Majesty is a beautiful deep crimson variety that has stood well this year, but, as I have never grown it before, I am unable to give its behaviour in different seasons. First crown buds are best.

Single Varieties.—Ceddie Mason, Mensa, Lady-smith, F. W. Smith, Kitty Bourne, Crimson Queen, Joan Edwards, Brightness and Miss Mary Anderson. *Preston Gardens, Linlithgow.* C. BLAIR.

A BEAUTIFUL FLOWERING CLIMBER.

THE plant illustrated on this page is an extremely beautiful climber, having the misfortune to be named *Polygonum baldschuanicum*. It makes many feet of growth annually and bears rosy-tinted panicles of flowers in great profusion both in early summer and again in autumn. Although suitable for clothing pillars, verandahs and buildings generally, it is unquestionably seen to the best advantage when allowed to cover old trees in the pleasure grounds. It appreciates a sunny position and fairly good soil.

C. Q

THE ICELAND POPPY.

THERE are few more beautiful hardy flowers than those of the Iceland Poppy, *Papaver nudicaule*, and it would be difficult to find any that are more highly appreciated for indoor decorations when cut. Unfortunately, they are not grown nearly so extensively as their charm and usefulness would justify, a fact that is no doubt due to the troublesome habit the plants have of dying off during the winter. As the plant is a native of the Arctic Circle, this mortality cannot be due to cold, but is undoubtedly brought about by the excessive moisture that characterises our winters.

To get over this difficulty many gardeners, and especially those who have wet, poorly drained soil to deal with, treat these Poppies as annuals, and for that purpose sow seed in boxes or pans of sandy soil in gentle heat early in February, subsequently pricking out and hardening off the seedlings so that they are ready for planting out early in May. Plants raised in this way commence to flower in July and continue to do so until well into the autumn. Another method, and one that answers well in many gardens, is to sow the seed outside, where the plants are to flower, about the second week in April, taking care to thin the seedlings early so that they stand about nine inches apart each way. Naturally, these are later coming into flower than those raised under glass in February, but if the following winter is at all favourable they will stand a much better chance of surviving than the earlier-sown ones.

Where the soil is of a sandy nature and, consequently, well drained, there is no doubt that the best results are obtained by sowing the seed outside, preferably where the plants can be allowed to flower, early in July. The resultant seedlings will not flower the same year, but during the May following, and thence onwards well into the summer, they will give such a profusion of blossom as to repay the cultivator for the trouble entailed. Even in gardens where the soil is none too favourable a few should be tried in this way, the making up of a bed of sandy soil going far towards enabling the pans to withstand the winter.

Those who have natural rocks abounding in the garden, or even old retaining walls where a fair amount of soil is available, can scarcely find more suitable flowers for growing there than the Iceland Poppies; in such positions June or July sowing is best. If, as will most likely be the case, the weather is very dry at the time, the soil must be watered frequently until the seedlings are well up and established. These Poppies can now be obtained in a number of beautiful shades, ranging from pure white, through yellow to deep cinnamon red.

PAPAVER.

THE PROPAGATION OF PLANTS.

"HEEL" CUTTINGS AND OTHERS.

I LITTLE thought when I penned the words appearing in *THE GARDEN*, November 7 last, page 541, as to the superiority of the joint-made cutting over that of the "heel," that the subject would have aroused so much interest or received such unqualified support. The endorsement of "H. P.," one of the best trained of the older school of London nursery propagators, is particularly esteemed,

A COLONY OF ICELAND POPPIES. THESE ARE VERY CHARMING HARDY FLOWERS FOR CUTTING.

since so few men have had so wide an experience as he. Of the value of the node or joint-made Carnation cutting over that of the "heel," one has but to compare the two to secure an immediate demonstration of the increased basal area of the former to that of the latter, and seeing that root fibres are presently emitted in proportion to those areas, there is only one logical conclusion to be drawn. Moreover, in the Carnation cutting of the "heel" pattern, there is ever present a short—or long—somewhat contracting neck, which may, or may not, prove a source of considerable danger or impediment to the future progress of

the plant. The danger lies in this contracting neck becoming hide-bound or even partially so, and, if this ensues, it plays the part of a throttle-valve, and no admixture of soils or cultural skill will ever make of such a cutting a really robust, free, continuously developing plant. In the joint-made cutting the same danger is non-existent; hence in this, of a surety, prevention is better than cure.

On the other hand, there are instances, notably among herbaceous perennials, where the "heel" is an essential to successful plant propagation. It is absolutely so, indeed, in the case of hollow-stemmed plants, of which the well-known Larkspur (*Delphinium*) may be cited as an example. Minus the "heel" it is impossible to root a cutting, or, if one perchance did form root fibres, equally impossible to make a plant. The reason is that in these hollow-stemmed plants the reproductive bases in the form of latent eyes or buds are only found concentrated about that portion of the stem which, forming a junction with the main rootstock, is, when severed, known to gardeners as the "heel." Such portions with young shoots attached root freely enough, though it is remarkable how large an interested number quite overlooked this important fact. In hollow-stemmed plants these reproductive eyes or buds do not appear to exist, though they certainly do, if in embryo, in the axils of other plants, e.g., *Phloxes* and *Pelargoniums*.

I suppose it is somewhere about twenty-five years ago—it may be more—since the late Rev. C. Wolley-Dod thanked me, through the medium of a contemporary, on behalf of hardy plant growers generally for disclosing the secret of rooting *Lychnis vespertina* from cuttings. Some years prior—in 1880, to be exact—I had successfully mastered the propagation of *Onosma taurica* from cuttings, and staggered the late Mr. T. S. Ware of Tottenham with a batch of stove pots representing about 150 plants, in which there was not a single failure. Both were exceedingly rare at the time, regarded impossibles from cuttings, and the "secret" of both—though I made no secret of it—was the "heel" cutting. Another plant which answered

to the same method was *Omphalodes Lucilæ*. This was in the spring of 1875. I had then a solitary plant, and, curiously enough, the number of cuttings obtained in my first attempt was thirteen, every one of which had rooted within a month. Indeed, one of the surprises with the above was their ready response, though it has to be admitted that the condition of the cutting and season of the year are important factors in rapid or successful rooting. In a manure frame I have rooted young basal cuttings of the white Everlasting Pea, when a comparative rarity, in eleven days, and though this popular subject

is easily increased from seeds, it is well to know that cuttings of the right sort will root so promptly in the event of a particularly good form turning up.

An interesting experience in respect to *Chrysanthemums* from "heel" cuttings merits recording. Having a small stock of an early flowering novelty I desired to increase, the stools were kept in the greenhouse longer than usual. Every inch-long cutting as it was ready had been secured and inserted *joint-made*. Requiring the space and not wishing to forego the smallest atom of a cutting, I stripped all the remaining shoots off with a "heel" attached and inserted them without more ado. Last rooted, they were also last planted, joining the others in the open quarters. In the result not one of these "heel" cuttings produced stem growth; but instead, first developed a proud leafy shoot, which at a few inches high ultimately reached the dimensions of a dinner plate and became stationary, when, the latent buds below coming into being, a mat of shoots a foot or more across was formed by every plant. There were 150 or 200 of them, not one of which produced either stem or flower. Beside them in the same quarter were between 2,000 and 3,000 others of the same variety propagated from nodal or joint-made cuttings, all of which flowered and gave every satisfaction. As stock plants the smaller lot was valuable enough, though that was no consolation to one who was growing the plants expressly for cut flowers; albeit it was an object-lesson of what *not* to do in the future in like case. The remarkable lateral development referred to I had seen often enough from stock increased from the strong, sucker-like growth of autumn, and when, in addition to gross growth, the standstill during the winter might have been made responsible for much. I had never before, however, seen this lateral development in the *Chrysanthemum* as the outcome of the freshly made cuttings of early spring and with a full season's growth *apparently*—I say it advisedly—*ahead*.

Plant propagation has always had a certain fascination for me, and I have been tempted to give these experiences in the hope that the rising generation of gardeners, not content with "As it was in the beginning, is now and ever shall be," should cast aside, in parts at least, the orthodox yoke, and, believing that there are in the sea as good fish as have ever been caught, experiment in the problems of propagation for themselves, the whole of which, I feel persuaded, are as yet unsolved. E. H. JENKINS.

DAVID'S PEACH.

THIS, *Prunus davidiana*, is the earliest of the ornamental Peaches to flower, the white blossoms frequently opening early in February. It makes a dwarf tree from 15 feet to 20 feet high, and if planted under the lea of a belt of evergreens receives some protection from cold winds, and shows off its wreaths of blossoms to the best advantage. It will thrive in almost any reasonably good soil.

THE MOUNTAIN CLEMATIS.

THESE are few more fascinating hardy climbing plants than the Clematises, or Virgin's Bower as some delight to call them. For many years they have rightly claimed an important position in our gardens, where their rambling flower-laden shoots, tumbling lazily about over pergola or tree, or hiding the face of some more or less ugly building, have endeared them to the hearts of all. Popular as the whole family undoubtedly is, there are a few kinds which stand out as universal favourites, and the doyen among these is undoubtedly the small, white-flowered Mountain Clematis, *C. montana*. This should be planted in a sunny position so that its growth can get well ripened in autumn.

In common with other members of the family, the Mountain Clematis must be planted in soil that is thoroughly drained, and if it contains a

admiration of every passer-by. There must be hundreds of trees about the country that could be made beautiful in this way at a very small cost, providing those who plant remember to keep the roots of the Clematis well out from the trunk of the tree and to place it on the sunny side. Rustic poles, formed of tree branches with side shoots left on, if rammed firmly into the ground, make ideal supports for this Clematis.

Some ten years ago the introduction of a rose-coloured variety of *C. montana* caused a great stir in gardening circles. Hailing from Northern China, where it was discovered by Mr. E. H. Wilson, it has proved perfectly hardy in this country, and although by some considered rather less vigorous than the white species, it is sufficiently strong-growing to quickly clothe a large area. Its botanical name is *C. montana rubens*. Owing to the colour of its flowers, it ought never to be planted against a red-brick wall, but against a pergola, rustic poles or bridge, as

THE ROSE-COLOURED MOUNTAIN CLEMATIS (*C. MONTANA RUBENS*) OVER A RUSTIC BRIDGE.

good quantity of lime, so much the better. If the natural soil is stiff clay, some sand, and, if obtainable, a little peat should be added, so as to make the whole more porous and thus assist the roots in their rambling search for food. Planting may be successfully carried out at the present time. Although the Mountain Clematis is well adapted for planting against walls, and particularly where its growths can run along and hang suspended from a balcony, I never think it looks more charming and natural than when flinging its slender, flower-bedecked shoots over the limbs of some old tree, for preference one with dark green foliage. Grown thus we get an excellent and pleasing contrast, and one that shows off the pure white blossoms to the best advantage. I have vivid recollections of a Mountain Clematis scrambling over an upright conifer by the lodges of a gardening friend, where the twain made a pillar of foliage and flower some thirty feet or more in height that must have been the

shown in the accompanying illustration, or, better still, living trees. A word of warning about pruning may be necessary. All that is required is an occasional thinning of the growths immediately after flowering. H.

A GOOD SHRUB FOR WINTER.

AT the present time, when outdoor flowers are scarce, we appreciate more fully those plants that possess either coloured stems, fruits or foliage. An interesting foliage shrub just now is the Jerusalem Sage (*Phlomis fruticosa*). This is of dwarf character, seldom growing more than 4 feet high, with wrinkled leaves that are, on the under side, covered with greyish white tomentum. The younger branches are also clothed with this woolly substance. It is a shrub that will thrive in almost any garden soil where the drainage is perfect, but in the London district should be given the protection of a wall with a south or south-west aspect. B. G.

GARDENING FOR BEGINNERS.

HOW TO FORCE SOLOMON'S SEAL AND LILY OF THE VALLEY.

MANY novices are deterred from taking up the culture of some of the most beautiful and easily cultivated subjects because they underrate their own ability and also because they imagine difficulties that seldom or never arise. In the present instance it is proposed

good plump crowns in a 5-inch pot. The crowns should be visible above the surface soil, as shown in the illustration. When the crowns have a somewhat shrivelled appearance, it is a good plan to soak them for an hour or two in tepid water before they are potted up; it is most undesirable to keep crowns out of the soil for any length of time. After potting give a good watering in, subsequently standing the pots in a cold frame on a bed of ashes for a few weeks. Cover the crowns with a good layer of moss, after having spread the latter out on the ground and thoroughly moistened it with boiling water to destroy slugs and insects. Introduce the plants to a gentle heat in the first instance, affording a brisk bottom-heat of about 80° later on. Bottom-heat is absolutely necessary to success. So soon as the buds begin to show the white of the blossoms, the pots should be removed from the bottom-heat and the plants gradually inured to a lower temperature. Tepid water should

sprout attained a length of about an inch in the case of kidney sorts, and half an inch in the case of second-early and maincrops, by the end of February.

Tubers for Warm Borders.—At this season it is a good plan to make a selection of tubers for planting on a warm, sheltered border. The best are chosen, placed 2 inches apart in a shallow box, and the space between filled with sifted soil and leaf-soil in equal quantities. This compost should just cover the crowns of the tubers, leaving the sprouts bare. The new roots quickly grow from the base of the sprout and firmly adhere to the compost, which has received one watering through a rosed watering-can. If the boxes can be placed in a house or frame from which frost can be readily excluded, the mass of compost will be filled with roots, and the sprouts will have attained a length of 3 inches in about six weeks' time. Then the tubers must be carefully lifted and planted.

Early Potatoes in Cold Soils.—I find this plan a good one also in the case of cold, clayey soils where early tubers are required for table. Whereas it would be unwise to plant the sets in the cold soil very early, it is an advantage to commence their sprouting in soil in boxes. The actual border planting may be put off until the soil has become warmer. In the meantime the tubers are growing, and the crop is secured earlier than if the tubers were planted without this special treatment direct in the cold, open border. Some temporary protection, with dry litter or other material, may be afforded against late frosts. With regard to the main planting, highly satisfactory results are forthcoming when the seed tubers are given special treatment, so as to secure strong sprouts on firm, green-skinned ones.

I have seen uncared-for sets, after being heaped throughout the winter and overhauled just prior to planting, that have yielded bushels of long, thin, white sprouts which have been thrown away, some of the sprouts being 1 foot long. **GEORGE GARNER.**

CROWNS OF SOLOMON'S SEAL ON THE LEFT AND LILY OF THE VALLEY ON THE RIGHT, SHOWING METHOD OF POTTING.

to deal with the following popular plants, viz., Solomon's Seal and Lily of the Valley. Each of these may be grown in pots under glass quite successfully by any reader who possesses a warm greenhouse.

The first of these interesting subjects is Solomon's Seal, known to botanists by the name of *Polygonatum multiflorum*. It is one of the handsomest of our native plants, and its merits as a pot plant have long been appreciated. The crowns may be potted up either in the autumn or early spring. Early potting ensures early flowering, and that is the only advantage of autumn potting. The crowns may be purchased cheaply, but where this subject is growing in the hardy border they may be dug up during the winter at the convenience of the grower. Solomon's Seal is an excellent plant for the conservatory, but it is well to point out that it does much better in a low temperature than in a high one. The Lily of the Valley-like crowns may be grown in any pots 5 inches or more in diameter. It is a mistake to crowd the crowns in the pots, and for this reason I have depicted on the left of the illustration a few crowns potted up in a 5-inch pot and an ideal specimen crown in the front thereof. Any ordinary light soil will answer the requirements of this subject. See that the soil is worked well round the crowns, and subsequently place the pots in a cold frame or under the bench of a cool greenhouse. They will begin to grow in a very short time, after which they will come on rapidly. Those who have the necessary crowns, and also the accommodation, should pot up a number of the strongest in 10-inch pots.

On the right of the illustration there is portrayed about a dozen crowns of Lily of the Valley potted up in a 5-inch pot. Crock the pots carefully to ensure good drainage, and place twelve to fifteen

be used for watering, and on no account must the soil be allowed to get dry. **D. B. CRANE.**

PREPARING POTATOES FOR PLANTING.

THE importance of having seed tubers well sprouted at planting-time should not be overlooked by cultivators. The "sets" must not be so exposed as to be frozen, else they will be quite spoiled; but if kept in a very cool shed and air and light are freely admitted to them on all favourable occasions, they will be ideal for planting in due course.

From the time when I first had the pleasure and advantage of the friendship of the late Mr. James Clark, the raiser of Magnum Bonum, Clark's Maincrop Kidney and other varieties of sterling merit, I have taken a great interest in the cultivation of Potatoes, and, in a small way, experimented in their culture, mainly in regard to size, shape, the lifting, preparation and storing of the seed tubers. I have found the best results from kidney sets that measured about two and a-half inches in length, and round or pebble-shaped sorts about two inches in diameter, crosswise. In setting up on end the seed tubers it was never a very difficult matter to secure an even lot. Not more than two sprouts to a set were allowed to grow, and if one good sprout was available it was retained, and all others rubbed off quite early. This

POTATO SETS THAT HAVE BEEN SPROUTED IN LIGHT READY FOR PLANTING. NOW IS THE TIME TO START EARLY VARIETIES.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Peaches.—Continue to disbud the trees at intervals till all the surplus growth has been removed. Where the fruits have set thickly, many of them may be rubbed off at once, leaving those which are facing the light; but where the fruits are sparse, thinning must not be done hastily. Syringe the trees twice daily in bright weather, and keep a moist atmosphere by damping the walls and floors two or three times a day. See that the trees do not suffer for the want of water at the roots. Old trees carrying heavy crops must be given a stimulant.

Fig Trees in Pots.—The trees which were started in November may now be given a slightly higher temperature, but do not use artificial heat to excess. The forcing should be done by taking full advantage of sunshine. A minimum temperature of 55° will be suitable for another month.

Permanent Trees.—Trees in active growth must be well supplied with water at the roots. Pinch the shoots at the fourth or fifth leaf and remove all superfluous growths. Syringe the foliage vigorously twice daily and keep the atmosphere moist by damping the paths, walls and floor. Prune late trees and thoroughly cleanse them with strong soapy water. If trees are too vigorous, they should be lifted and replanted, giving them plenty of drainage and a restricted rooting area.

Plants Under Glass.

Freelias.—These must now be liberally treated in regard to watering and feeding, or the flowers will be weak. A batch may now be safely moved into a warmer house to hasten their flowering.

Lachenalias.—Keep these growing near the glass in a cool house. When the flower-spikes appear, the plants may be given a warmer house should it be necessary to hasten their flowering. Now that the pots are full of roots, stimulants may be afforded.

Cyclamen.—The old plants may be encouraged to flower for some time yet by careful watering and feeding. Remove old flowers and decayed leaves regularly. Admit air to the house according as outdoor conditions will allow. The seedlings raised last autumn will now be ready for a shift into 2½-inch pots. Plunge the pots in fibre quite close to the glass, or, failing this, stand them on a moist bottom of sand or fine ashes. Syringe the plants twice daily and keep the temperature of the house at 60° or 65°.

Propagation from Cuttings.—The propagation of various plants, such as Crotons, Dracænas and other stove subjects, must now be attended to. Old plants of Fuchsias and Heliotropes may be placed in moderate warmth, where they will make suitable growth for cuttings.

The Flower Garden.

Carnations.—When the ground is dry enough, give the surface a light dusting of soot; then lightly stir the soil with the hoe. In exposed situations a few evergreen boughs placed among the plants will protect them from cold cutting winds and severe frost. Rabbits and game are known to be very destructive to Carnations, and means must be taken to protect them. Keep the lights removed from plants in frames, except during severe weather. They will need little water at the roots, but must not be allowed to become too dry.

Roses.—Some of the more tender varieties, especially those which have been recently planted, will need protection should severe frost set in. Branches of evergreens placed among plants form a suitable protection. Standards or climbing varieties may easily be protected by adjusting the same materials about them by means of string. The pruning of climbing Roses must be brought to a close, or much damage to the young growth will occur.

Violets in Frames.—Admit plenty of air to the plants when the weather is suitable, removing the lights altogether on favourable occasions.

Remove decaying leaves and flowers regularly, and always keep a look-out for slugs. A surface-dressing of fresh soil and manure will be of great benefit to the plants.

The Hardy Fruit Garden.

Apricots.—The training of Apricots to wires needs great care, for the least damage to the wood may be the cause of canker, a disease to which they are very subject. While spurs must be encouraged along the branches, it is also wise to encourage a young growth here and there, as these may be useful for filling up gaps caused through branches succumbing to canker. Trees which are inclined to be too strong should be root-pruned, and when adding fresh soil use plenty of broken bricks and old mortar rubble. Young trees should be lifted. Manures should not be used in making borders for the Apricot.

The Kitchen Garden.

Broccoli.—During mild weather the heads will continue to turn in; therefore the plants must be frequently gone over, removing those which are ready to a cool shed.

Jerusalem Artichokes.—These may be taken up now, so that the ground can be prepared for their cultivation during the coming season. Providing the ground is well manured, this crop may be grown on the same ground year after year. The small tubers may be selected for seed, using the larger ones for culinary purposes.

Globe Artichokes.—During mild weather any protecting material which has been placed over the plants must be removed. Only in the case of very severe frost should the plants be covered.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Tree Carnations.—Cuttings which were inserted during December will now be sufficiently rooted for potting up. Pot singly in 2-inch pots and keep in a close frame for about ten days. After this the ordinary conditions of the Carnation-house will suit them if placed on a shelf near the glass.

Caladiums.—An early batch of these may be started into growth now. Shake out of the old soil and place several together in 5-inch and 6-inch pots; then plunge in bottom-heat in the stove. If large specimens are required, the plants must be potted on into larger size pots while the leaves are developing. Let the compost be rich in peat, leaf-mould and coarse silver sand.

Schizanthuses.—Plants raised from a sowing made now will be useful for furnishing the flower-house in midsummer. They will not, however, grow so tall as the autumn-sown plants.

Cypripediums.—These Orchids are of very simple culture, and are valuable winter-flowering plants. Their lasting qualities are well known. The flowering of most varieties will be past, so now is a good time to pot. The compost should consist of good fibrous loam, coarse silver sand, sphagnum moss, and either good peat or Osmunda fibre. For large specimens the mixture should be left in a rather rough state.

Potting Materials.—Plenty of turf and leaf-mould should be got under cover, so that it may be in good order for the large amount of potting that will be done during the next few weeks.

The Hardy Fruit Garden.

Gooseberries.—If the bushes have previously been sprayed with some bud protector, pruning should now be completed. Where bullfinches are rife and the bushes unprotected, pruning had better be delayed for quite another month.

Raspberries.—The splendid season of 1914 produced good canes, which give promise of a heavy crop should the conditions be favourable at the time of flowering. Being strictly a surface-rooting plant, it is unwise to disturb the soil

to any extent where they are growing. Never at any time should forking be done at a greater depth than 2 inches or 3 inches. Well-decayed farmyard manure is most suitable for Raspberries.

Planting.—Before making a new plantation of Raspberries, the ground must have a liberal dressing of manure, which is best dug in some weeks previous to planting. If planted in rows, 3 feet is a good distance to allow between the plants, and 6 feet at least must be left between the rows.

The Kitchen Garden.

Early Peas.—The present will be quite early enough to make a first sowing, which should be done in pots or boxes. If the seeds are to be raised in boxes, sow them on long pieces of turf, which can be readily planted in rows without disturbing the roots. Guard against rats and mice, which are very fond of Peas.

Hot-Beds.—Preparations should now be made for making an early sowing of Carrots, Radishes and Leeks. A hot-bed should be formed of fresh stable litter, to which has been added plenty of clean leaves, turning these over so that they become well mixed. When the bed has been firmly trodden and the frame got into position, some light soil ought to be put in. This should not be more than 4 inches or 5 inches in depth. Sow the seed broadcast, and if room is to spare, a few Lettuces may be pricked out at the same time.

Fruit Under Glass.

Peaches.—Trees in the Peach-house which was started during mid-December will now be mostly set and passing out of flower. Disbudding should be done gradually and with judgment. The trees should receive a good syringing daily, except during sunless weather. Ventilate very carefully, especially while frosty winds are blowing.

Vines.—The second vinery may now be closed, but will not require much artificial heat. A night temperature of 55° to 60° will be ample. Endeavour to keep a fairly humid atmosphere by regular syringing of the Vines and keeping the evaporating pans full of water.

Pot Strawberries are very subject to attacks from green fly and red spider. The green fly can be got rid of either by fumigation or the application of an insecticide, but neither must be used when the plants are in flower. Red spider can be largely prevented by keeping the under sides of the leaves well moistened. If red spider is already in existence, care should be taken not to let the plants come in contact with other plants or fruit trees. As soon as the Strawberries are set, the fruit-stalks should have some support. Thin twigs will be sufficient to hold up the fruit, and each plant should be restricted to five fruits. Frequent applications of liquid manure must be given when watering.

The Flower Garden.

Standard Heliotropes.—Continue to remove side shoots until the desired height of the plants has been reached. As young plants are preferable to old ones, it is a simple matter to grow them each year. Growth is very rapid if the plants are kept in a stove temperature, to which they do not object. Afterwards, when the heads are being formed, they may be given slightly cooler conditions before being finally planted out of doors in June.

The Wall Garden.—When forming a wall garden, the builder should have an eye for the artistic. Formality must be absent. Stones that are porous and of a rustic appearance are best. Try to make the face appear uneven, yet for strength a certain amount of regularity must be observed, leaving occasional stones protruding and others receding. The stones must also be placed in such a manner that they will receive all rains, which will drain in to the roots of the plants. The larger plants are best built into the wall as the work proceeds. This prevents breaking the roots, which would inevitably happen if planted after the building work has been completed. It must be seen that the plants do not suffer from want of moisture until established.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

HYBRID STREPTOCARPUS.

FOR the vast improvement which has taken place during recent years in this charming flower, we are probably more indebted to that veteran florist, Mr. John Heal, V.M.H., to Messrs. J. Veitch and Sons of Chelsea, and to Mr. William Watson, Curator of the Royal Gardens, Kew, than to anyone else, each having done yeoman service in hybridising and popularising this now, I might almost say, universal plant. Not only is there an improvement in the size of the flowers, but almost every shade of colour is present, except yellow. In addition, the length of footstalk is much greater, which renders them suitable for all kinds of floral decorations, and the flowers, fortunately, last for a considerable time in a cut state. Suitably arranged with Orchids, when a proper selection of colours is blended, they make a charming table decoration. I have, during the past fifteen years or so, done what I could to help in the direction of improving what I believe will be for some years to come one of the most appreciated flowers, when its cultivation becomes better known than it is at the present day. One distinct advantage is that with proper care and attention the same plants may be had in flower at least from early April until the middle or end of November. A mistake too often made is that the *Streptocarpus* is treated far too much as a stove plant rather than as a greenhouse subject.

Seed-Sowing.—The seed should be sown early in the new year, either in well-drained seed-pans or pots. The surface on which the seed is to germinate should be fine and made moderately firm, and the seed (which is very minute) scattered evenly over the surface. Press this well in and do not cover it with soil. The whole should be thoroughly moistened by standing the pot or pan in a pail of water to the rim. A piece of glass should be placed over the top, after which transfer it to the shady part of a warm house until germination (which is rather slow) takes place, and subsequently place it near the glass, but shade from bright sunshine. Immediately the seedlings are large enough, prick them into shallow boxes or pans, and grow on in the same temperature, taking care to protect them from bright sunshine.

Treatment of Seedlings.—Directly the young plants show signs of making their second leaf, they should be potted singly in 3-inch pots, which should be well drained, using a soil composed of two parts light loam, the same of well-decayed leaf-soil, and one part of coarse silver sand. These may be grown on in an intermediate house until they become established, always bearing in mind that the *Streptocarpus* is a shade-loving plant, and the foliage must never be allowed to become burnt. They may then be removed to a slightly heated pit, placing them on a bed of ashes as near the glass as possible, shading the latter with white-wash or some other suitable material. The plants must never be allowed to suffer for the want of water. The young plants should begin to flower about the middle of August, and, if a good strain has been selected, it will be found extremely interesting to watch their development. Each one of note should be labelled and these particular plants placed together for growing on the following season.

Treatment of Plants.—All worthless varieties should be rejected. During November and December

the plants ought to be kept in a greenhouse temperature, allowing them to become moderately dry to give them the needed rest, and during January, after giving them a thorough soaking of water, pot on the plants into 5-inch or 6-inch pots. These must be well drained and a few quarter-inch bones placed on the top of the drainage, after which some good fibre, taken from the loam heap, should be placed thereon to prevent the soil clogging the same. The soil for this potting should consist of good fibrous loam three parts, one of good leaf-soil or peat, one also of good silver sand, and a 6-inch potful of finely broken potsherds may be mixed to every half-bushel of soil. Pot very firmly, and start the plants into growth in an intermediate house, but rather err on the side of giving too little than too much fire-heat. Never exceed a maximum of 60°. Raise the plants as near to the glass as possible, be sparing of water until they become well established, and do not damp the foliage overhead, but give plenty of moisture by syringing between the pots, the walls and paths. As soon as the plants have plenty of roots in the new soil, manure-water of medium strength should be given every third watering, and when in full flower this may be increased to every other time. I have found nothing to suit them better than that made from horse and cow manure in equal proportions, to which should be added a small bag of soot. Clay's Fertilizer, by way of a change, is a safe and valuable manure when applied according to directions. To ensure the plants continuing to flower for a long season, the old flower-stalk and seed-pods should be removed, except, of course, any which may be wanted for seed purposes.

Insect Pests.—The two most troublesome of these we have to deal with in relation to *Streptocarpus* are green aphid and mealy bug. The latter should never be allowed to come into contact with the plants if possible, and green fly may be kept in check by fumigating the plants about once in ten days or a fortnight with XL All. The most suitable house for flowering the plants during the summer and autumn months is a low span-roofed one, and during hot weather a moderate amount of air must be given both day and night. The same plants may be grown on for several years, but I have found it preferable to raise young plants annually and throw the old ones away after the second year's growth.

Propagation by Leaves.—The propagation of any special variety may be easily done by means of leaves. This is best performed early in the spring. The midribs of the leaves should be placed round the outside of a pot in some place in a warm house, and these will throw up young plants from the base.

E. B.

SEASONABLE NOTES ON VEGETABLES.

Peas are an important crop. They are more appreciated than any vegetable, except it be the Potato, which is such a universal requirement that it will always rank as of the greatest importance. Those who have the convenience—a cool house—should sow five seeds in 9-inch pots of such sorts as Edwin Beckett, Duke of Albany and The Pilot. Fill the pots to within 2 inches of the top with a rich compost, leaving this space for future top-dressing. Sow in a temporary pit, or a heated one if possible, seeds of an early dwarf variety in rows 15 inches or 18 inches apart,

according to the variety. If a warm border is available, sow seeds of dwarf early sorts in well-prepared trenches 6 inches deep, with light compost in the trench and over the seeds, which will drain off surplus water from heavy rains if the subsoil is heavy in character. This compost will ensure quicker germination of the seeds.

Broad Beans should be sown in drills 3 feet apart on a warm border. The soil should be in as dry a state as possible, or add a compost of lighter material in which to place the seeds, and thus ensure quicker germination. Early Windsor and Longpod are still the best varieties for the first sowings. At the end of this month make a sowing in boxes in a cold frame of the same varieties for planting out to ensure a full crop, as this method sometimes comes in useful in the event of seeds sown in the open in the autumn or in January not coming up successfully.

French Beans.—Those who require pods in February or March should sow seeds of any small-growing variety at once, four seeds in each 3-inch pot, placing them in a temperature of 65°. When the plants show their first pair of leaves, transfer them to 6-inch pots in a light compost. Keep the pots close to the glass in the same temperature by night, with a rise of 10° by day; syringe as the weather permits, and supply the roots liberally with water to prevent an attack of red spider, which is not only injurious to the Beans, but is apt to infest other plants near, Strawberries, for example.

Onions for Exhibition of the Ailsa Craig type should now be sown in boxes of sandy soil made quite firm. Sow the seeds evenly about an inch or so apart. Overcrowding is a mistake, as the plants should grow sturdily from the start. If they once become weakly through being drawn up for want of space, they never regain that robust condition so essential to success. Now that Onions over 3lb. each are yearly produced, it behoves exhibitors to ensure the best results. If the soil is moist at sowing-time, water will not be required for a few days; but on no account must it become dry, or the germinating powers of the seed will be impaired. Place the boxes in a heat of about 60°, such as a newly started vinery or Peach-house affords. Directly the plants show through the soil, stand the boxes on a shelf close to the glass to ensure sturdy growth, and keep the roots well supplied with water.

Carrots of the Short Horn type should be at once sown on a gentle hot-bed in rows 9 inches apart, using sandy soil 6 inches in depth on the leaves or manure employed for the bottom-heat. Keep the frame close until the plants show through the soil; then ventilate carefully to induce sturdy growth. As soon as the plants are large enough to handle, thin them to 2 inches apart. This distance will enable an early pulling of quite young roots, and then leave a full crop to grow to a larger size.

Potatoes.—For the earliest crops place one full-sized tuber in a 10-inch pot three parts filled with light compost in which decayed leaf-mould plays a prominent part. The space at the top is reserved for earthing as the plants progress, and thus keeps the haulm firm and feeds also the surface roots. Stand the pots in a newly started vinery or other structure with a similar temperature. Ringleader, May Queen or Sharpe's Express are good sorts for this crop. For planting in frames later, the tubers should be spread out on end to sprout, thinning the sprouts to two on each as they progress. Too many sprouts are

a hindrance to the best results in all forms of Potato culture.

Radishes.—Wood's Frame and French Breakfast types should be sown in the frames containing the Carrots, Peas and the earliest Potatoes, as the conditions here are most suitable.

Parsley should now be sown in boxes in a gentle heat. Should the supply appear to be running short, prick out the plants in other boxes directly they are large enough to handle, and from here really good plants will be available for putting outside on a warm, sunny border, where a full crop will quickly be available. One variety is sufficient. That should be of a close, thickly curled nature, of which there are abundant types, so many, indeed, that it seems quite unnecessary to grow the badly curled, straggling variety too often grown in gardens.

Leeks.—To have the finest specimens at the end of August or early in September, the seed should be sown in January, as a long season of steady growth is required to obtain the full length of stem which is so much admired, and which is one of the chief features in a perfect specimen. Sow three seeds in a 3-inch pot of light, rich soil, thinning the plants to one in each pot directly the best can be discerned. This ensures a thorough start, the ultimate end being regulated by attention to all necessary details. Stand the pots in a moist heat of about 55° or 60°. Directly the plants show above the soil, the pots should be stood on a shelf close to the glass in the same structure. Water carefully, but little is required for a time beyond occasional syringings overhead during fine weather.

E. MOLYNEUX.

Swanmore Park, Bishop's Waltham, Hants.

NEW PERPETUAL-FLOWERING CARNATIONS.

THE following varieties of Carnations have recently been registered by the Perpetual-Flowering Carnation Society. The particulars have been sent to us by Mr. T. A. Weston, St. John's Road, Orpington, Kent, who is the hon. secretary of the society. He will be pleased to send full particulars of membership to anyone interested in Carnations.

Delice.—Clear pink, Enchantress sport. Award of merit, December 2, 1914. Raiser, Mr. H. J. Dudney, South Road, Erit.

Caprice.—Pale pink, flaked red, seedling. Raiser, Mrs. C. H. Seeley, Wingerworth Hall, Chesterfield.

Grenadier.—Coral red, seedling. Raiser, Mr. W. J. Reed, gardener to the Countess of Derby, Coworth Park, Sunningdale.

Bishton Wonder.—Rosy lilac, seedling. Registered by Messrs. Allwood Brothers, Hayward's Heath.

Wivelsfield White.—Pure white, seedling. Raisers, Messrs. Allwood Brothers.

Colleen.—Salmon pink, seedling. Raiser, Mr. C. Engelmann, Saffron Walden.

Nora West.—Salmon pink, seedling. Award of merit, December 2, 1914. Raiser, Mr. George West, Gables Nursery, Datchet.

Mme. Chas. Page.—Apple blossom pink, seedling; Perpetual Malmaison type. Raisers, Messrs. R. Veitch and Son, Exeter.

General Joffre.—Scarlet sport from Lady Northcliffe. Registered by Mr. George Clarke, Leighton Buzzard.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

DOUBLE-FLOWERING CAMOMILE (Grace Gardner).—We regret we are unable to inform you at present where you are likely to get the double-flowered Camomile though doubtless it is still to be found in old-fashioned gardens in many parts of the country. It is true that Belgium has, in the past, been one of the chief sources of supply of this medicinal herb, though it is also grown largely in some parts of Surrey. In the latter, however, if memory serves us rightly, we believe the single variety—usually considered of the best medicinal quality—is that most frequently grown, though it is highly probable that the double-flowered form, owing to a much greater yield of flowers, is that chiefly grown on the Continent. With so many Belgian refugees now in England, that point could doubtless be easily cleared up. As to the plant we have seen in Surrey, we will endeavour to ascertain which it is, and, if successful, will write you further.

TREES AND SHRUBS.

HOLLY BRANCH FOR INSPECTION (S. M. Martineau).—The section of Holly branch sent for examination has been bored out by the larva of a moth. It may have been done by one of two species, *Cossus ligniperda* (Goat Moth) or *Zeuzera æsculi* (Wood Leopard Moth)—which, however, it is not possible to say without seeing the caterpillar.

FRENCH LILAC (F. A. R.).—The name of French Lilac is applied to the common Lilac (*Syringa vulgaris*) and also to the bulbous plant *Muscari comosum* var. *monstrosum*. It may also be applied to other plants. If you send us a specimen of the plant in question when it is in good growth, we shall be pleased to determine the botanical name and advise you as to culture.

MAGNOLIA TO NAME (Garden Lover).—Your plant of *Magnolia grandiflora* may be pruned back fairly hard in April. By severe pruning you will probably lose most of the flowers for one year, but the only way to get the plant back to the wall is to remove the longest branches and tie the others back. By lightly pruning every year, plants may be kept fairly close to walls.

AMPELOPSIS ARBOREA (C. H.).—The plant referred to as *Ampelopsis arborea* is also known as *Vitis arborea*, and is a native of the Southern United States. It is usually most satisfactory when grown against a wall in this country, but it is not easy to obtain. English nurserymen do not appear to stock the plant, and it is likely that it would be most easily procured direct from America. Try Messrs. P. J. Berckmans and Co., Nurserymen, Angasta, Georgia, U.S.A.

DOUBLE-FLOWERING MOCK ORANGES (G. S.).—There is now a very wide choice in double-flowered Philadelphuses. The most vigorous is *P. coronarius* flore pleno. This grows to a height of 6 feet or more, and has a similar habit to the common Mock Orange. *Boule d'Argent*, *Manteau d'Hermine* and *Virginal* are dwarfer, with rather smaller flowers. They grow 4 feet or 5 feet high eventually, but are rather slow, and give the best

results when pruned each year and kept between 3 feet and 4 feet high.

POPLARS FOR AVENUE (South Stafford).—The question as to which of the two trees, *Populus nigra* pyramidalis (Lombardy Poplar) or *P. alba* bolleana (Boll's Poplar), is the better one for an avenue depends more upon the taste of the planter than upon anything else. Both are perfectly hardy and thrive under exactly similar conditions. There is, however, a difference in habit, for, whereas the Lombardy Poplar is usually of columnar outline when mature, Boll's Poplar is, as a rule, pyramidal in habit. The Lombardy Poplar often branches from near the ground, while the other kind has usually a section of clear trunk. Of the two the head of Boll's Poplar is rather looser than that of the other. Boll's Poplar has a slight advantage over the Lombardy variety in the fact of its having greyish bark and greyish leaves, which give it a lighter appearance. The main differences are as stated, and there is little to choose between the two. Boll's kind perhaps has the advantage in the fact that it is more uncommon than the other kind. Select straight, sturdy trees with clear and distinct leading shoots, and be sure to notice that the roots are well furnished with fibres, as those trees with plenty of fibrous roots transplant more satisfactorily than others which may have a few thick roots only. The cause of Lombardy Poplars becoming bushy and not growing well in height is that the leaders have not been kept clear of rivals.

THE GREENHOUSE.

CHRYSANTHEMUMS TO BLOOM AT CHRISTMAS (Constant Reader).—In addition to the varieties you name the following should be grown: Mrs. W. Buckbee, Niveus and Mrs. David Syme, white; Nagoya and December Gold, yellow; A. J. Balfour, pink; Heston Pink; and Tuxedo, bronze and orange. The last-named may be had in bloom till as late as the middle of January, and also Godfrey's Perfection, a pure white Anemone-flowered variety that is very free and fragrant. Of singles, Wellesbourne Beauty, yellow, and Mme. Melba, cream, flushed pink, are good late sorts. Of feathery varieties, Mrs. W. Butters is the best late white. White Mrs. Filkins and Cheveux d'Or, yellow, are good. Cuttings should be propagated from early in January to the end of February. The best results do not accrue from high cultivation in the case of late varieties. Use good loam, pot firmly and feed moderately, so as to produce firm wood during the dull days of autumn.

TREATMENT OF POINSETTIA PULCHERRIMA AND PLUMBAGO ROSEA (Enquirer).—When the bracts of *Poinsettia pulcherrima* are faded, they should be cut off and the plants placed in a structure where a temperature of 50° to 60° is maintained. They must then be kept dry, but not absolutely parched up, in order to give them a season of rest. Then during the latter part of April they should have the soft portions of the shoots cut back, and the plants placed in a warmer structure, giving them water at the roots and an occasional syringing. This will lead to numerous young shoots being pushed forth, and when these are nearly three inches long they will be ready to be taken as cuttings. The cutting should be formed of the entire shoot, with its swollen base just where it starts from the old wood, as from this spot roots are freely produced. Each cutting must be inserted in a small pot, which must be clean and well drained. A suitable compost for the cuttings may be made of loam, peat or leaf-mould and sand, the whole being well rubbed through a sieve with a quarter of an inch mesh. The cuttings must then be plunged in a gentle bottom-heat in a propagating-case, where, if care is taken not to over-water, they will soon root. When rooted they must be exposed to the ordinary atmosphere of the structure in which they are to be grown. A minimum temperature of 60° is very suitable for them then. They will soon be ready for shifting into pots 5 inches in diameter. A suitable soil for *Poinsettias* is good loam, lightened by an admixture of leaf-mould, dried cow-manure and sand. When the weather gets warm, the plants may be placed in a frame and inured to air and light in order to induce a sturdy growth. By some the plants are again shifted into 6-inch pots, but, in any case, as the pots get full of roots, weak liquid manure must be occasionally given. Though *Poinsettias* may be kept in a frame during the summer, they must not be left there too late in the season, otherwise the bottom leaves will turn yellow and drop. Early in September they should be placed in a structure where an average temperature of 60° is maintained. As soon as the bracts are seen, they will be increased in size if a little additional heat is given. When developed they keep better in a cooler and drier atmosphere. Though *Poinsettias* are usually grown annually from cuttings, the old plants may readily be grown and flowered a second or third year. Those intended for growing on should be cut back harder than those needed to supply cuttings. A good plant will produce several shoots, and, as each carries a head of bracts, a bold, showy specimen will be the result. These old plants may be grown in pots 6 inches, 7 inches or 8 inches in diameter, according to their vigour. Specimens such as these are especially valuable for grouping in the conservatory or for similar purposes. *Plumbago rosea* should, after the flowers are over, be cut back into shape, but not too hard. In an intermediate temperature young shoots will soon be pushed forth. When these are about half an inch long, the plants may be repotted, a clean, well-drained pot a size larger than before and a mixture of loam, leaf-mould and sand being very suitable for them. Their after-treatment may be much the same as that advised for *Poinsettias*. Should it be desired to increase the stock of this *Plumbago*, cuttings from 2 inches to 3 inches in length may be put in as soon as they are obtainable

and, grown on like Poinsettias, they will make neat flowering plants by the winter.

IVY-LEAVED PELARGONIUMS AND PLUMBAGO CAPENSIS (H. D. M.).—The Ivy-leaved Pelargoniums should be wintered in a light structure where a minimum night temperature of 45° or thereabouts is maintained. Of course, the thermometer will run up higher during the daytime, but a free circulation of air should be given whenever possible. With regard to watering, enough water should be given to keep the soil slightly moist, but an excess must be strictly guarded against. This does not mean that you are to give water in little drops, but to wait till the soil is nearly dry, and then give enough to moisten the whole of it. In an ordinary greenhouse about every three weeks would be quite sufficient, but with regard to time no hard-and-fast rule can be laid down, as so much depends upon the house itself, the weather experienced, and other matters. Watering when required should be carried out in the morning, as then there is sufficient time to dry up any superabundant moisture. For this reason a fine day should be chosen on which to water the plants. By no means should the plants be watered during sharp frosts, as it is much better to leave them dry when the weather is severe. In this way the plants will safely pass through the winter in a quiet condition, and will start freely into growth when the spring comes round. The Plumbago will, in a greenhouse, pass through the winter in a quiet state, and many of the leaves will frequently die off. You state that your plant was pruned in the beginning of December, but is not doing very well. You cannot expect it to start into growth in the depth of winter; indeed, the quieter it is kept at that season, the more vigorous will be the growth when the proper time comes round.

ROSE GARDEN.

SPRAYING ROSES WITH COPPER SULPHATE (W. T.).—One spraying should be sufficient for Roses against mildew, using a pound of copper sulphate to twenty-five gallons of water, and it should be done before the buds burst, otherwise it is likely to do them harm. Pruning away the parts affected in previous years should be a great aid in keeping them clean.

GLOIRE DE DIJON PLANTED IN NOVEMBER, 1913 (Rustie).—It would have been best had you cut back the plants to about two feet in the spring of 1914, but as one has good growths inside, it would be advisable to leave it alone this season, merely tipping the growths. The other plant cut back to about six inches in March; it should then send out good canes next summer.

STANDARD ROSES FOR NORTH GARDEN (D. C.).—Your conditions are too exacting, and we fear you will not obtain all you want. Many Roses that would do are not fragrant; others that are fragrant have not a long season of flowering. Then, again, there are few really orange and copper Roses that are fragrant. We give the following good varieties as near your requirements as possible: Mme. Abel Chatenay, Conrad F. Meyer, Laurent Carle, Gloire de Dijon, Bouquet d'Or, Juliet, Mrs. D. Jardine, General Macarthur, Liberty, Mme. Jean Dupuy, Soleil d'Or and Duchess of Wellington. The plant you have as Hugh Dickson is no doubt wrongly named.

ROSES FOR FRONT ROW (L.).—We advise you to plant The Lyon Rose in the front row, and in place of this variety substitute Cissie Easlea, a good mildew-proof Rose, admirably adapted to plant in the position mentioned. Then in the front row, following The Lyon Rose, we can recommend Mme. Leon Pain, Lieutenant Chaire, Souvenir de G. Prat, Countess of Shaftesbury, Molly Sharman Crawford, Mrs. Edward Powell and Duchess of Wellington. We have avoided the sorts you say you have already, namely, Mme. Ravary, Mme. A. Chatenay, Prince de Bulgarie, Caroline Testout, Frau Karl Druschki and Hugh Dickson. Should you desire any other varieties, we can strongly recommend Louise Catherine Breslau, Ophelia, Marquise de Sinety and Melody.

KITCHEN GARDEN.

TOMATOES IN BOXES (Grace Gardner).—The boxes you refer to would certainly not be too large, probably the reverse, seeing that the Tomato is a very gross feeding subject. The size of the receptacle is, however, but one item of the programme, and a good soil mixture, with ample top-dressings and artificial manures when the fruits are set and swelling, are of equal, if not even greater import. We have never yet had any occasion to thin the fruits, the usual experience being that they do this themselves, the swelling fruits leaving the others behind. When it is observed that the fruits are well set and swelling, then you may begin feeding and top-dressing, gradually at first and subsequently more liberally. By earthing up above the box with good turfy loam, the top-dressings will greatly assist the productiveness of the plant, particularly if liquid manures are used in conjunction therewith.

HOW TO GROW SMALL, CRISP CELERY (Mrs. F. R. Clarke).—Growers of vegetables generally favour the growth of large specimens of most kinds, although it is well known among most of them that by doing so quality to a serious extent is sacrificed and much waste in Celery, as in other things, occasioned, as a large number of the leaf-stalks of these huge specimens are thrown away. In the first place, varieties have some bearing on this question. Some are large, and others of medium growth to small. These latter are the best to grow for home consumption. The best among these are Sandringham

White and Major Clarke's. Other causes are applying too much manure to the soil and planting too far apart. Too much feeding with highly stimulating liquid manures will help to produce the results complained of. Caution has to be exercised in not running to the other extreme of not applying enough manure to the soil, as a crop of good quality Celery cannot be grown without a generous application of manure. The best and most economical way of growing Celery, especially if moderately small plants are the desideratum, is to plant in beds rather than in single rows. Such beds should be 5 feet wide and 10 inches deep (the soil taken out of the bed to be banked by its side to come in for earthing up later). The rows should be planted across the beds and be 15 inches apart, and the plants in the row 6 inches apart. Celery is a moisture-loving plant, and during dry weather must be copiously watered.

MISCELLANEOUS.

LAWN THIN IN PLACES (M. M. K. C.).—You cannot do better than rake as much as possible of the moss out of your grass at the present time; then, during the early part of March, prick over all the bare places with a fork and sow new seed, afterwards giving the whole lawn a good dressing of fine rich soil. It is too early to sow fresh seed now.

VARIOUS QUESTIONS (Hants).—Makers of small propagators.—W. Pearce and Co., 648, Holloway Road, London, N. Spanish Iris.—When the plants are well up, a dose of weak liquid manure about once a fortnight will be helpful. Care must, however, be taken not to give an excess of stimulants. Tuberous Begonias.—There is no advantage in starting the tubers of Begonias in Cocoanut refuse; indeed, it is very much better to start them in some good soil, such as two parts of loam to one of leaf-mould and a liberal sprinkling of sand. The tubers should be potted at the end of February or early part of March. Pots 4 inches in diameter are very suitable for them, and, in potting, the tubers should be put at such a depth that they are just covered with the soil. They must not have much water till they start into growth, and only need the temperature of an ordinary greenhouse, that is to say, from 45° to 50°, increasing, of course, as the days lengthen and the weather gets warmer. It is very essential that the plants are well hardened off before they are bedded out at the end of May. After April a cold frame is the best place for them, just throwing a mat over the light in the event of frosty nights and giving plenty of air during the day.

NAME OF PLANT.—D. W., Surrey.—Chimonanthus fragrans.

SOCIETIES.

SOUTHAMPTON ROYAL HORTICULTURAL SOCIETY.

ANNUAL MEETING.

The annual meeting of this society was held on Monday, the 11th inst., in the Council Chamber, the Mayor, Alderman W. Bagshaw, presiding over a satisfactory attendance. The Mayor spoke of the influence of the war upon the society, complimenting the members upon the fact that their operations had not been affected financially. The annual report stated: "Owing to circumstances arising from the war your Council, in common with many other societies, deemed it prudent to abandon the autumn show. Had the exhibition been proceeded with, it would probably have resulted in a considerable loss. Arrangements have been made to hold three shows in 1915. The Council will use every effort to carry through this programme. The Rose show held at South Stoneham last July was again a financial success. The balance sheet showed a highly satisfactory balance of £50 4s. 3d., in addition to which, as the secretary mentioned at a later stage, a debt of £25 had been liquidated from last year." The chairman of the Council, Mr. Molyneux, presented the report, and spoke gratefully of the support given to the society by Ellen Lady Swaythling in allowing the Rose show to be held at South Stoneham House, and by Lord and Lady Swaythling. The society was also indebted to Lord and Lady Northbrook, the latter of whom opened the summer show, and to the donors of special prizes. Mr. A. W. Oke seconded, expressing his gratification at the condition of the society as shown in the report. The finances were, he noted, in a highly satisfactory state. The report and accounts were adopted. It was decided, at the suggestion of Mr. Molyneux, to give donations of five guineas each to the Royal Gardeners' Orphan Fund and the Gardeners' Royal Benevolent Institution out of the funds of the society.

The re-election of Lord Swaythling as president was proposed by the Mayor, Mr. E. Kemp Toogood seconding and speaking of Lord Swaythling's close personal interest in the society's affairs. The members agreed. The vice-presidents, a lengthy list, were re-elected, with the addition of Sir J. Beetham Whitehead of Eford Park, Lymington, and Mr. Maldwyn Drummond of Cadlands. Other elections were as follow: Hon. solicitors, Messrs. Green, Moberly and Green; chairman of Council, Mr. H. E. Molyneux; vice-chairman of Council, Mr. D. Desborough; hon. treasurer, Mr. A. G. Thompson; secretary, Mr. C. S. Fuidge (who was first appointed to the post in 1873); members' auditor, Mr. A. J. H. Marshall; Council (a third of its strength), Messrs. F. Chandler, T. Hall, F. Green, A. J. Marsh, A. Tofield and F. J. Hendy.

BIRMINGHAM AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

ANNUAL MEETING.

THERE was a large gathering of members at the Athletic Institute on Monday, the 11th inst., it being the annual meeting. The proceedings opened with the reading of the minutes of the previous meeting, followed by the secretary's presentation of the 1914 balance sheet and report. On examination these disclose the receipts during the past year to be £34 11s. 3d. (including the balance of £4 9s. 4d. brought forward from 1913) and the expenditure as £30 6s. 4d., thus leaving at present in hand a balance of £4 4s. 11d. The assets of the society were also proved at £349 6s. 4d. Afterwards the election of a committee for the current year took place, ballot papers being handed to each individual member. Out of the twenty-two nominations, sixteen were eligible for election, and the voting resulted in the return of Messrs. R. Usher, P. Catt, J. Markham, J. Palmer, R. T. Parker, A. D. Christie, J. Higley, T. Humphreys, S. Smith, H. Ford, C. H. Herbert, A. Cryer, A. B. Brown, J. Webb, W. Spinks and W. L. Deedman as the executive for 1915. Having obtained a committee for the year, the appointment of officers was the next consideration. Eventually, in spite of the withdrawal in turn of these six who had so ably served for 1914, Mr. C. H. Herbert was prevailed upon to again act as chairman, Mr. A. Cryer as vice-chairman, Mr. A. R. Brown as librarian, Mr. J. Webb as assistant-librarian, Mr. W. Spinks as treasurer, and Mr. W. L. Deedman as secretary, so that the society has once more assured itself of the good services of these gentlemen. A recent revision of the library had entailed much extra trouble to the librarian and his assistant, and as a recompense a much deserved vote of thanks was tendered to them. Also the kindness of the Press was by no means overlooked, for during the past year it had upon several occasions rendered valuable assistance, for which the society is deeply indebted. A formal vote of thanks was proposed by Mr. Herbert and seconded by Mr. Spinks. Before the meeting terminated, a sympathetic reference was made by the chairman touching the death of Mr. W. B. Latham. Not only had the deceased been a trustee of the society, but he was also the society's first chairman, and it is with deep regret that the intimation of his death is received.

SCOTTISH HORTICULTURAL ASSOCIATION.

WITH the notice of the annual general meeting of this association on January 19, the usual abstract of accounts for the year ending December 31, 1914, has been circulated among the members. The Chrysanthemum show accounts exhibit an income of £1,079 5s. 4d., including £360 4s. 3d., the net takings from the sale of plants, &c., at the stalls arranged for the Red Cross and Belgian Relief Funds. Donations came to £90 2s. Takings at the gate and tickets sold amounted to £526 9s. 4d. On the other side of the account, awards, including medals and engraving of cups, accounted for £250, and music came to £225. Other items of expenditure brought the expenses up to £788 13s. 5d., leaving the highly satisfactory balance of £290 11s. 11d., of which amount £145 6s. went to the Red Cross Society and £145 5s. 11d. to the Belgian Relief Fund. The association is to be congratulated on this most successful result. The ordinary revenue accounts are less satisfactory, as there was a deficit on the year's working of £26 2s. 1d., but the expenditure included an item of extraordinary expenditure of £10, this having been voted to the Extension Fund of the Edinburgh and East of Scotland College of Agriculture, while the funds suffered from the entire net proceeds of the Chrysanthemum show being devoted to the relief funds above mentioned. The ordinary income, which includes £160 14s. from members' annual subscriptions, amounted to £215 19s. 8d. In the capital account depreciation is allowed on stocks held by the association. The Horticultural Institution Fund account shows that this fund, after allowing for depreciation of stocks, now stands at £1,615 3s. 3d. against £1,493 18s. 7d. the previous year. The Benevolent Fund accounts show a credit balance of £12 19s. 10d. The whole position reflects great credit on the management.

DUMFRIES AND GALLOWAY GARDENERS' ASSOCIATION.

AT the usual meeting of this association, held in the Wesley Hall, Dumfries, on January 9, a series of questions and a discussion thereon occupied the meeting. Mr. S. Arnott occupied the chair. Mr. W. Hutchinson reported that the amount collected for the Royal Gardeners' Orphan Fund had been sent, and produced the treasurer's receipt for the same. The questions asked by the members were then drawn by lot and a discussion took place upon each, practically the whole of the members present taking part, and a most interesting and useful evening was spent.

GLASGOW FRUIT TRADE BENEVOLENT SOCIETY.

The Glasgow Fruit Trade Benevolent Society's annual meeting was held in Glasgow on January 11. The president, Mr. J. H. Thomson, occupied the chair, and remarked upon the favourable position of the society, there being an increase in membership and in funds, while there had been no claims by members during the year. Equally satisfactory reports were given by Mr. J. Russell, treasurer, and Mr. H. Stuart Girvan, clerk, that of the treasurer showing that the funds stood at £1,220 13s. 5d., this being a gain of nearly £120 upon the previous year. Office-bearers were appointed, these including Mr. John H. Thomson, president; Mr. James Gardiner, vice-president; Mr. James Russell, treasurer; and Mr. H. Stuart Girvan, clerk and collector.

THE GARDEN.

No. 2254.—VOL. LXXIX.

JANUARY 30, 1915.

NOTES OF THE WEEK.

Our Sub-Editor at the Front.—The following letter, dated January 15, from our Sub-Editor, Mr. H. Cowley, who is serving with His Majesty's army in France, will, we think, be of interest, especially the reference to the glow-worms and violets: "In spite of the shortage of labour, the farmers seem to have their land in remarkably good condition. The soil around here is fertile and of great depth, although waterlogged in places owing to the heavy rains. These are points brought home to us very forcibly in our trenching operations. By the way, one point that strikes me as curious when trenching at night is the number of glow-worms giving off that vivid phosphorescent light which I had always associated with summer-time in England. There are signs of an early spring, if one can be guided by the forward condition of the buds of certain trees. This morning, while in a sheltered copse, I came across a party of French boys with their caps full of fragrant Violets! This is a puzzling time for a naturalist who would fain write of peace in time of war. Before leaving England I was much impressed by a sentence in a book I was then reading: 'The people who cannot, or will not, be as men in the duty of battle can hardly be as men in the security of peace.' Although our life is a hard one, there is not a man among us who would return to his occupation, however delightful that may be, until his duty at the Front has brought about peace with honour."

Apples for Wounded Soldiers.—We are pleased to learn from the Hon. G. Eden, whose appeal for Apples for wounded soldiers in the Victoria Hospital we published in our issue of January 9, that sufficient for the needs of the soldiers there have been supplied by our readers.

Snow on Evergreen Trees and Shrubs. The heavy fall of snow experienced in many parts of the country on Friday last calls for a word of advice to those who have evergreen trees or shrubs in their gardens. Owing to the density of the foliage of many of these, the weight of snow that lodges on the branches is a source of considerable danger. Some years ago we saw several very fine old Cedars with large branches broken off by the weight of snow. Wherever practicable, steps should be taken to remove the snow as quickly as possible. With large trees this is naturally difficult, but with young ones, and also choice shrubs, the task is an easy one.

The Day Lilies in Pots.—Although the various kinds of *Hemerocallis* are seldom seen as pot plants, they are excellent for this purpose, and will be found very valuable where a large supply of flowers is required to keep the greenhouse or conservatory gay at all seasons. They give little trouble and afford a pleasing variety. Although the individual blooms may only last a day, a succession is kept up for a considerable period. Where there are clumps established in

GYPSOPHILA REPENS GROWING IN A DRY WALL. IT HAS WHITE FLOWERS AND GREY FOLIAGE.

the open ground, they should be lifted now, potted into suitable sized pots, and placed in a cold frame. All that is necessary is to water the plants when required, and as the roots get active a little liquid manure will be beneficial.

Help for Aged and Infirm Gardeners.—At a period such as this, when so many calls are being made upon the purses of the charitable, we hope that our readers will do their utmost to support

the Gardeners' Royal Benevolent Institution. From the report of the annual general meeting, held on Thursday of last week, which appears on another page, it will be seen that only fifteen out of the sixty-two thoroughly deserving candidates could be elected for pensions. This Institution, which is non-political and non-sectarian, was founded seventy-five years ago, and since then has distributed many thousands of pounds in the form of pensions to aged or infirm gardeners, or their widows. We have no hesitation in saying that the Institution is run on extremely economical lines, and anyone who can possibly subscribe to its funds should do so. We noticed in the report that several owners of gardens during last summer opened these to the public, making a small charge for admission, the money thus obtained being sent to the secretary, Mr. G. J. Ingram. His address is 92, Victoria Street, Westminster, and he will be pleased to furnish anyone interested with full particulars of the work of the Institution.

A Charming Wall Plant.—*Gypsophila repens* is an indispensable dwarf subject of prostrate growth, succeeding on any well-drained, sunny slope of the rock garden or showing to singular advantage when draping the face of some sun-exposed dry wall. It forms close mats of prostrate stems, abundantly clothed with narrow, sharp-pointed leaves of a grey green hue. It is also typical of the Gauze Flowers in the hazy effect produced by the innumerable small, starry blossoms that are borne on the terminal shoots and branch out so as to almost completely hide the leaves. In the type plant the flowers are invariably white, but when raised from seed these show many small variations in form, which, although minute in detail, are sufficiently pronounced to give distinction to the best forms, and is most readily appreciated where they afford ready means of comparison, as in dry-wall garden-

ing. *Gypsophilas* are frequently spoken of as chalk plants, owing to their remarkable vigour in soils containing this substance, the species under notice being no exception. It is readily propagated by cuttings taken during August and inserted in sandy soil in an unheated frame, or seed sown in the autumn or spring germinates freely and yields plants that flower the following year.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Benthamia fragifera Fruiting in Surrey.—

In reference to your note on this shrub, page 23, issue January 9, it may interest you to know that a plant in the garden of the late Miss Ewart, Coneyhurst, Surrey, bore fruit last year. It has been planted eight years, and did not flower until 1913. It is quite hardy there, planted on a lawn sloping to the south-west. There is also a plant at Viscount Alverstone's place which also flowers and fruits.—H. S.

Cabbage Little Gem.—I commend this choice little Cabbage to other amateurs who, like myself, have small space for vegetables. I use it as an autumn Cabbage, and have been cutting it from November till now. It takes very little room in the garden, having few waste leaves; but its great merit is its quality. It is a Cabbage for the gourmet, not for the gourmand. It has only one fault—it makes one discontented with every other Cabbage until the harbingers of spring appear again upon the table.—ANNE AMATEUR.

Cuttings with "Heels."—Having seen in THE GARDEN notes on the subject of taking cuttings with "heels" or without, I write to tell you my experience with wickuraiana and multiflora Rose cuttings. I have always been interested to strike some in old medicine bottles in the house. I cut them about eight inches or nine inches long with a heel, and about four inches to five inches of each cutting is in water. In almost every case the cutting roots at every bud where I had stripped off the leaves, and never at the heel. Very often it does not root within 2 inches of the heel. When well rooted and potted up in sand and leaf-soil, the cuttings soon make excellent plants. I cut off the bit of wood below where the first roots start. I gather from this experience that with Roses a heel is useless.—G. T. PORTMAN DALTON, Fillingham Castle, Lincoln.

The New Zealand Flax at Home.—In your issue of April 18, 1914, you have a paragraph from a correspondent re New Zealand Flax which is somewhat misleading, to the effect that its natural habitat is on "land subject to winter inundation, and on sandy and shingly river banks." I have lived on the south end of New Zealand for the last fifty-six years, and when I was a boy many places in Dunedin were covered with Flax, and from the variety of places it grew I would say it will grow (here at least) on almost any land. The largest and most prolific plants I have seen, however, grew on stiff clay land above any inundation. They were so high and thick that children could get lost among the plants or bushes. I have grown it in my garden, where it thrives almost too quickly, as it soon took up too much space. I have in my present place new, young bushes, plain green, variegated and brown, on the side of a steep incline, where it is necessary to use water-hose for growing vegetables.—J. BEADLE, Dunedin, New Zealand.

Shows, Schedules and Judges.—"Exhibitor's" letter, page 26, issue January 16, will do much good if it is the means of inducing committees who are engaged in drawing up schedules to be as explicit as possible in the wording of the various classes, so as to make the conditions as plain as possible for the benefit of exhibitors and judges. Too many words are used in defining some classes,

at the expense of clearness. Judging from considerable experience of the framing of schedules and shows generally, I find that the members of committees, who are well versed in their work, always try to improve and profit one year from the previous year's experience, and so on. With one or two exceptions, committees I have worked with have always tried to obtain the services of judges who are experts in the work they are called upon to do. There may be, and undoubtedly are, exceptions in many other instances, and they should be reduced to vanishing point. "Exhibitor" seems to be rather hard on committees in reference to trade exhibitors, but he may have evidence of importance to bear him out. My experience is that trade exhibitors have had full consideration because the value of their exhibits was realised. More help would be given, undoubtedly, if it could be afforded. I would like to add that all concerned should now do their utmost to work together in the near future in view of the conditions obtaining through the war, and so keep all matters connected with gardens and the interest in them more firmly impressed on the public mind. Well-managed shows have a great influence for good.—GEORGE GARNER.

MY GARDEN OF HOPE.

("It is the time of seed catalogues. They are heaped beside my elbow as I write. Are the seed-growers a little 'previous' this year, or is it that we, somehow, are not quite ready for them?")

You have brought me a touch of the Spring

When dull hearts for its freshness are aching :
There's a fragrance wrapped up in your leaves

And a sigh from the season that's waking :
In a stamped, sealed and signed envelope,
You have brought me my Garden of Hope.

Here's a border of Pansies and Pinks,

There's a bunch of Sweet Peas for the picking :
A lavish reward for slight cares

Of sowing, transplanting and sticking !
There are Larkspurs and Lupines galore,
And Gilliflowers . . . close at my door.

You have brought me a touch of delight,

Just when hearts for its promise are pining :
With catalogues heaped at my side

Plots, borders and beds I'm designing :
It's fine for the Springtime to wait,
With your hand on the latch of her gate !

ELIZABETH KIRK, in *Country Life*.

Ginkgo biloba.—Your correspondent "J. H. D." asks in your issue of January 16 what the French call this tree. According to Loudon it is known as *Arbre aux quarante écus*, and he states that the origin of this curious name was that a M. Pétigny in 1780 bought five of these trees from an English gardener for about forty crowns (*quarante écus*) each, and introduced them into France (see Loudon's "Arb. and Frut.," IV., 2096). Carrière also gives the name as a synonym, but places the introduction earlier. May I add that there is a very beautiful specimen of the pendulous form in the Champs Élysées in Paris. In the early summer, when the leaves are fresh, the tree presents much more the appearance of Maidenhair Fern than the rather stiff habit of the type. The tree stands in a somewhat secluded spot behind the Grand Palais. I have unsuccessfully attempted to photograph it more than once, but any of your readers who care to find it out will, I think, admit that it presents a most graceful appearance.—G. W. E. L.

A Hedge of Sorts.—In reply to "Anne Amateur's" enquiry in THE GARDEN of January 9, page 14, the following four Crabs are very beautiful: *Pyrus coronaria flore pleno* bears the largest flowers. *P. floribunda atrosanguinea* bears a mass of bloom and small fruits. *P. Malus neidzwetzkyana* I think the best; crimson blossoms, followed by crimson fruits. *P. Scheideckeri* is of rather stiff and rigid growth, but bears exquisite flowers, followed by small fruits. Crab John Downie is very good, both for its bloom and its brilliant fruits, which make excellent jelly. May I suggest for autumn and winter colour *Quercus coccinea* (Waterer's variety), the Scarlet Oak, *Amelanchier canadensis* (Snowy Mespilus), Japanese Cherry James H. Veitch (double rose), *Cytisus scoparius præcox* (the buff-coloured Broom), *Forsythia suspensa* (yellow flowers in March), *Halesia tetraptera* (Snowdrop Tree); varieties of *Philadelphus* (Mock Orange) *Fantaisie*, *purpureo-maculatus*, *Satsumi* and *Voie Lactée*; *Rhus Cotinus purpurea* for autumn colour, *Ribes atrosanguinea*, *Rubus deliciosus*; *Spiræas Aitchisonii*, *arguta* and *Thunbergii*; *Syringa* (Lilac) varieties *alba grandiflora*, Dr. Lindley, *Souvenir de L. Späth*, *Mme. Lemoine* and *President Grévy*; *Viburnum plicatum* (Japanese Snowball Tree) and *Weigela Eva Rathke*. These are deciduous.

The following are evergreen: *Cistus* of sorts, *cyprius* and *ladaniferus* (Gum Cistus), *Cotoneaster pannosa*, *Elæagnus glabra folio-variegata*, *Olearia stellulata*, *Rosmarinus* (the common Rosemary), *Viburnum rhytidophyllum*, *Bamboos Arundinaria nitida* and *Phyllostachys aurea*, and *Buddleia variabilis magnifica* (should be cut down every spring). These are selections from a "hedge of sorts" now four years old.—C. ECHLIN GERAHTY.

Crinum Powellii.—It may interest your correspondent, whose notes have appeared recently, to know how *Crinum Powellii* may be made to thrive and flower abundantly in North Yorkshire on a very cold clay soil. It is first to be remarked that frost penetrates the ground to a much greater depth in light, sandy soils than in stiff clays, and in the summer the sandy soil warms up much more readily than the clayey soil, so that those who live on warm, sandy soils must plant their *Crinums* deeply. I have myself seen newly planted bulbs rot after severe frost, even when planted more than a foot below the top of the bulb, in Surrey. On the contrary, a bulb planted deeply in cold clay soil may exist, but will start so late that flowering will come late, and most probably not at all. With these data in view, I planted a good bulb of *Crinum Powellii* seven years ago at the foot of a south wall absolutely above the ground-level, merely digging and manuring and sanding the soil, mounding up the soil round the bulb to a height of 18 inches above the level, and then putting some stones to keep the fresh soil in place. With the protection of a little litter and manure in the winter, no plant could succeed better or flower more freely than this has done. Another bulb I planted deeply in a south border. It existed and, indeed, grew fairly well after the month of June had warmed the soil, but it only once succeeded in flowering in September, and I have now taken it up and potted, it to replant above the surface in the spring. This will explain why some may recommend deep planting and others surface planting. As a matter of fact, the surface-planted bulbs do, after some years, pull themselves down by their strong roots deeply into the ground.—EDWARD H. WOODALL.

English and Irish Roses in Southern Scotland.—The Rev. David R. Williamson writes: "After the middle of May the garden of Kirkmaiden Manse, with whose culture, adequate or otherwise, I have been so long identified, will pass into other hands. I will not be far away from its precincts, however, and will probably be able to record from time to time in the columns of *THE GARDEN* its floral achievements. I will also do my utmost to imbue my ecclesiastical successor with my own love for horticulture. For some time past I have been planting many of the latest Rose introductions in the garden at Kirk House, Kirkmaiden, where I will be residing by the beginning of June. Notable among these are such superbly endowed varieties as Majestic, from the famous nurseries at Waltham Cross; the exquisitely beautiful Lady Clanwilliam and its fair companions Brilliant, Mrs. Archie Gray, William Cooper and Mrs. James Lynas, raised by Mr. Hugh Dickson of Belfast; Mayflower (a greatly improved *Devoniensis*) and other precious varieties from Mr. Prince of Oxford; Mme. Edouard Herriot, Irish Fireflame, and those glorious creations of Mr. Samuel McGredy of Portadown in Ireland, viz., Colleen, Edgar M. Burnett (described as 'the sweetest-scented Rose in existence' and a distinct advance on *La France*), Florence Forrester, Iona Herdman (a grandly decorative Rose), and the deep orange yellow Mrs. Ambrose Ricardo. There also I hope to cultivate some of the finest of the *wichuraiana* Roses, especially White Dorothy, Hiawatha and Christian Curle, of very charming salmon pink complexion, raised and introduced some years ago by Messrs. Cocker of Aberdeen. At the garden of Kirk House (which has a sunny aspect and fertile soil) I have borders already prepared for *Antirrhinums*, Sweet Peas, Oriental Lilies and other flowers, which are sure to luxuriate there."

Mildew-Proof Roses.—In your issue of October 31 last there appeared, by your courtesy, a note of mine on "Mildew-proof Roses," asking for a statement from Rose-growers as to their experience of the relative powers of resistance in the best Roses. Including my own note and your appended list, eleven growers have given their experience with one Rose or another, and I desire to thank you and your various correspondents for a series of notes from which I have derived much pleasure and an amount of valuable information which will very considerably modify the Rose orders which I am now making out. At some future time I may ask you to indulge me with a little space in which further to discuss this interesting question in the light of the remarks made by your correspondents, but in the meantime it may interest you and your readers to know the tabulated results of your little symposium on mildew in Roses. I do not guarantee its absolute accuracy, but it may be taken as at least roughly correct. From first to last 102 Roses have been mentioned as possessing greater or less resistant power. Of these, one has received five votes, viz., General Macarthur, and one, four, *La Tosca*. Eight have received three, viz., Lady A. Stanley, Ulrich Brunner, Château de Clos Vougeot, Mrs. D. McKee, Grüss an Teplitz, Mme. Ravary, A. R. Goodwin and Lieutenant Chauré. Thirteen have been twice mentioned, viz., *Félicité*

Perpétue, Jersey Beauty, Jessie, Dorothy Page-Roberts, Miss Cynthia Forde, M. Paul Ledé, *Beauté de Lyon*, Gustav Grünerwald, Duchess of Wellington, Mme. Melanie Soupert, J. F. Barry, *Boule de Neige* and Zephyrine Drouhin. This leaves about eighty Roses which were recommended by only one writer. You will notice that your own list is well sustained by the plebs. Those who desire a few Roses fairly immune against mildew cannot surely go far wrong in planting the first ten at least. As regards those Roses twice recommended, there are one or two which I do not grow, and about which, therefore, I cannot speak. I can well believe, however, that the resistant power of this batch is above the average. At the same time, one or two, for instance, Mme. Melanie Soupert and Jersey Beauty, are undoubtedly offenders with me. Let me further say that among the planting schemes

LILIUM COLCHICUM, A STately SPECIES WITH LEMON-COLOURED FRAGRANT FLOWERS.

I have in prospect is a Rose hedge 33 feet long, to grow to a medium height, say, 3 feet or 4 feet. Of course, I wish to plant varieties little susceptible to mildew; for what could look more forlorn than a mildewed hedge? I think of planting the Roses 18 inches apart, and the varieties I have in view are *Boule de Neige*, Grüss an Teplitz, General Macarthur, Florence H. Veitch, Homère, Old China, Lady Waterlow, Zephyrine Drouhin and Sarah Bernhardt. These would make a fragrant hedge I think, though I doubt whether General Macarthur would reach the height. A yellow Rose is wanted. Would Duchess of Wellington be sufficiently robust? I should like Harry Kirk, but mildew forbids. Mrs. David McKee is a prime favourite of mine. It is, however, not exactly a yellow, and, notwithstanding its three marks, it mildews with me. But what an exquisite Rose it is, and such a "laster"!—SOMERSET.

SOME HARDY LILIES.—V.

By SIR HERBERT MAXWELL, BART.

(Continued from page 40.)

SUB-GENUS MARTAGON.

Lilium canadense, a graceful thing bearing in July drooping flowers of warm yellow tinted with fawn, delicately spotted. The rhizomatous bulbs should be set 5 inches deep in free soil full of leaf-mould or peat, shaded from intense sunlight and kept moist. It is not a showy Lily, but a very charming one.

L. chalcedonicum, the Scarlet Turk's-cap.—If this Lily is lacking in some of the grace which is the peculiar attribute of the family, it atones for it by the dazzling scarlet of its crown of flowers, which is so well set off by the grey-green leaves that cluster closely along the sturdy stems. These stems rise to a height of no more than 2 feet to 3 feet;

the bulbs, therefore, should be planted where they will not be overshadowed or crowded by ranker growths. A native of Asia Minor and the Eastern Mediterranean region, the Scarlet Turk's-cap is a lover of sunshine, but the best plants I have are growing among low shrubs. It is not a stem-rooter, therefore the bulbs may be planted only 4 inches deep, its requirements in soil and position being similar to those of the Madonna Lily, with plenty of lime. It used to be as easy to manage as the Orange Lily, but for some years past it has suffered frightfully from attacks of Botrytis, and should be regularly sprayed from the beginning of May. It is a late flowerer; in the South the blossoms open in July, but in Scotland it is generally August before they appear.

L. colchicum (syn. *monadelphum*).—If I were limited to the cultivation of three species of Lily, the choice would cause me long and painful deliberation, so many cherished favourites would have to be shut out; but I cannot doubt that, in the end, this Caucasian beauty, for which no English name has yet been devised, would be one of the trio. Lily experts may smile superciliously, for it is a plant of easiest culture; but I am devoid of ambition; loveliness, not the bubble reputation, is what I covet, and this delightful Lily is lavish of her charms. Robust enough to rise to a height of 5 feet or 6 feet, and to stand erect without crutches or staking under the weight of its cluster of lemon-coloured bells with scarlet anthers, it scents the summer air with delicious fragrance and exacts homage to its chaste splendour from every visitor. For the very life of me I cannot understand why

it is to be seen in so few of the many richly furnished gardens which abound in the British Isles. Possibly it is more liable than other Lilies to get destroyed in spring-cleaning; for although it is almost, if not quite, the earliest Lily to flower, it is among the latest to show above ground. Equally perverse is the behaviour of *L. auratum* and *L. speciosum*, which outstrip all others in early growth, yet postpone flowering till the rest are done. Another reason for the infrequency of *L. colchicum* is that it requires two or three seasons to get established. Imported bulbs should always be potted, kept in a cool frame, and not planted out till they manifest strong growth. Then let them be set 5 inches deep in strong loam, with or without lime, and left alone for years. Hitherto, this species, with its varieties *monadelphum* and *szovitzianum*, have proved immune from disease; at all events, during thirty years

or so that I have grown it, I have not known it to suffer from the most malignant of all plagues, Botrytis, although many of its neighbours have endured that scourge. It may be that the Evil One is but biding his time; it will be a sorrowful hour when the blight first shows upon the shining foliage of this beauty. Imported bulbs of *L. colchicum* should on no account be suffered to flower in the first year after planting; indeed, the plant often refuses to make any appearance whatever above ground until the second year, when, if the bulb was clean and sound when planted, it will grow away and flower as if nothing had happened. An admixture of wood-ashes in the soil is a good antiseptic for bulbs in a dormant state. There are many varieties of this Lily, the finest being the golden-flowered kind named *szovitzianum*.

L. Humboldti.—There are two varieties of this fine Lily. One, the type, native of the northern part of the Sierra Nevada, has baffled all but the most skilful cultivators in attempting to establish it in European gardens; the other, entitled *L. Humboldti magnificum*, from the mountains of South California, is more accommodating, though not to be reckoned as everybody's plant. The treatment recommended is to set the bulbs nearly a foot deep in a sunny place in gritty loam, with or without lime. I have had it for some years and it produces its beautiful flowers twenty to thirty in a raceme, large turn-caps of ruddy gold, splashed and spotted with purple; but only once has it reached the height of five or six feet which it ought to attain, and, sad to say, it is more prone to dwindle than to increase, whether in numbers or in size. Wherefore it appears that I have not yet hit upon the right treatment. No pains are too sedulous to secure success, for this is a prince among the turn-cap tribe. It flowers in July.

L. Kelloggii was discovered not many years ago in California by Mr. Purdey. It is a very choice thing, and although I have not tried my hand with it yet, I have seen it blooming free and fair in Mr. Grove's garden, so there is no reason to despair of its future in this country. At present it is one of the rarest Lilies in cultivation. In form and manner of growth it is a refined model of the common Martagon. The Turk's-caps open white, then flush into rose and pass into purple. Deep planting, 9 inches or 10 inches, is recommended by those who have succeeded with this Lily, in a light, gritty soil with plenty of leaf-mould and faultless drainage. As it is easily raised from seed, it is likely soon to come within everybody's reach.

L. Marhan is one of the few hybrid Lilies whereof the parentage is known for certain. It is the offspring of *L. Martagon* and *L. Hansonii*, and it is a pity that the result is not more pleasing, for it is splendidly vigorous and healthy, putting forth flowers lavishly at a height of 6 feet. It is most refreshing to see the great blunt shoots pushing through the ground in early spring, as bold and massive as those of the Crown Imperial (*Fritillaria*); but the blooms, though finely shaped and gallantly borne, are of an unattractive brownish orange with dark spots. Stiff, sound loam, with peat or leaf-mould and with or without lime, satisfies its requirements.

L. Martagon is the only one of the genus which has become naturalised in Great Britain. It

occurs in some of the Southern Counties in situations such as have led some botanists to reckon it indigenous; but the freedom with which it scatters its seeds and the ease with which they germinate are enough to account for its dispersal. The typical plant, with flowers of a dull pinkish purple, is a graceful thing, but not worth a second thought compared with the white variety, which is one of the loveliest Lilies in existence and as free as it is fair. The robust variety, *L. Martagon dalmaticum*, is considered by Elwes to be a distinct

LILIUM MARTAGON ALBUM, A BEAUTIFUL HARDY VARIETY WITH WHITE FLOWERS.

species, and not without reason, for it grows 7 feet or 8 feet high, flowers a fortnight later than either the common or the white Martagon, and clothes its buds with a dense white down. Its perianth is of very dark but shining purple, nearly as dark, sometimes, as what is called the Black Tulip. The Martagon Lily, in all its forms, is as hardy a plant as the gardener has to deal with, and indifferent as to soil. Mr. Grove mentions a stiff loam as producing the best results, but I have seen *L. M. dalmaticum* 6 feet high flowering

with great luxuriance in peat and granite sand at an altitude of 1,200 feet in the west of Inverness-shire; although as it is a native of Dalmatia, where the prevailing rock is limestone and the sun very powerful, one would have expected a transition to the sloppy climate and acid soil of a Highland hillside would overtax its constitution. Notwithstanding its easy nature, many persons after paying a heavy price for the bulbs of *Martagon album* and *dalmaticum* (2s. 6d. and 3s. 6d. apiece) have been disappointed in the result. There is

but one reason for that, namely, that whereas the Martagon Lily rests for a very short time, it must be moved early in autumn. To delay planting till it suits the nurseryman's convenience to send the bulbs, probably in November, is to put a strain upon the constitution which it will not bear, and this applies to many choice bulbs besides the Martagon. The seed which these Lilies produce so freely is worth collecting and sowing in the open; for although the seedlings do not all come true to the parental variety, some of them will.

L. pardalinum, the Panther Lily, is a Californian species of the highest degree of merit, and almost, if not quite, as simple in its requirements as the common Martagon. It will thrive and make a brave display in conditions very different from those it seeks in a wild state; but to see it at its best, plant it in moist loam or peaty soil, give it space for the rhizomatous roots to spread, and in time it will reward you with a conflagration of red and yellow in July and August such as it is worth a long journey to see. I have in mind Lady Dartmouth's wild garden at Patshull, which contains a well-sheltered boggy hollow whereof the Panther Lily has taken complete possession, tossing masses of flaming blossom to a height of 6 feet or 7 feet. This Lily has wandered into an immense number of varieties in flower, foliage and stature, that everyone may indulge his taste for colour by choosing those in which crimson, orange or clear yellow predominates. In the variety *Johnsonii* the prevailing hue is cherry red. Mr. Grove has raised a beautiful hybrid between *L. pardalinum* and *L. Humboldti*, clear yellow sharply spotted with purple. I have seen this Lily in his garden bearing an immense mass of flowers on stems 8 feet high.

L. Parryi.—We have got among the difficult Lilies now, that is, those which exact thoughtful treatment and deft handling. That it responds generously to these, I have witnessed ample proof in Mr. Grove's border; but not having possessed the plant long enough to emulate his success, I can only advise the reader to consult pages 98 and 99 of his "Lilies," whence it may be learnt that means should be devised to mitigate the extreme of summer drought by subterranean irrigation, and of winter wet by a complete system of drainage. Deep and moist alluvium

without lime is the soil affected by this Lily in its native Southern California, and as no frost to speak of visits that region, the bulbs must be planted fully 8 inches deep to stand our winter cold. Above all, the drainage must be rapid. The reflexed petals of Parry's Lily are canary yellow, charmingly in contrast with the deep orange anthers. I have placed it among the Martagons, to which it bears a strong resemblance; but I am told it should be in the *Eulirion* group.

(To be continued.)

DAFFODIL NOTES.

"Somerset's" Perfect Catalogue.—If "Somerset" (December 16, 1914) is the "Somerset" who kindly made himself known to me at one of the Royal Horticultural Society's shows in the spring of 1913—I think it was at the Daffodil Show—he is an old hand at Daffodil-growing, and, as a perusal of his very interesting remarks seems to indicate, he at any rate has not been caught by the snare of the fowler. Still, he obviously has, if he is serious—which somehow I doubt—a grudge "of sorts" against the "much-respected" and "well-known" firm of "X. and Sons" of Pimlico (or somewhere) because they will pepper the names of the Daffodils in their list with small crosses, which, according to himself, have fallen, or have not fallen, where he would like to see them. What a dreadful thing for him to stand before his Glory of Leidens or his Minnie Humes next spring with the thought rankling in his mind that "X. and Sons" had only given each of them but two crosses! I am really sorry for his having such a thin skin, and I assure him that, judging catalogue compilers by myself, we who have *volens volens*, as it were, to appraise the relative values of the different varieties have no wish whatever to appear to be "gratuitous and a trifle officious."

The explanation is simple. All depends upon the point of view from which the variety is judged. It is open to "Somerset" or anyone else to say that a catalogue drawn up almost wholly from a show standpoint is all wrong; but I think he will see that he is going a little too far when he seems to suggest that the one or two crossed ones are only "poor trash after all." I am sometimes told that a variety I am very fond of is "rotten" and "no good." I have got, thank God, a duck's back, so I listen, civilly I hope, and then go on my way rejoicing. Let "Somerset" or anyone else have the courage of their opinions and let the catalogue compilers have theirs; this is the only way to solve the personal difficulty. If I like a variety and grow it in my garden, I would not mind in the very least how many crosses it had—no,

not even if it appeared among the discarded kinds of the Royal Horticultural Society's Classified List.

John Bull has not been in a trade catalogue for twenty years or more, but no Daffodil yet born is more satisfactory in grass and open woodland. It is different altogether when "Somerset" suggests that the apportionment of crosses and the basting of the different varieties with alluring words and phrases may be misleading. It probably is so sometimes. A purchaser who wants a few "rather better" varieties for his garden may not realise that all the marks and adjectival phrases in the list refer to the judgment of a show judge, and only in a very minor degree to a plant's garden value. The only suggestion I can make is that traders should state this fact very prominently, or, if it is not so, that they should make a point of letting all would-be purchasers know what standard their marks or remarks refer to. I hope in time that the Royal Horticultural Society's "Daffodil Year Book," coupled with the introduc-

tion of the new awards, may do much for those whose only object in buying Daffodils is to decorate their gardens. We must take a leaf out of the National Rose Society in the way it issues lists of the best sorts for various purposes. Our attempt in 1914 I look upon as a start.

If this can be sufficiently developed, I do not see why it should not be copied *en bloc* into every trade list. Perchance, however, "Somerset" would resent even this as an interference with the liberty of the Daffodiler to think what he likes because something else besides that *long bald* inventory of points (THE GARDEN, page 612, Vol. LXXVIII. column 3) has been included in it. It seems obvious that "Somerset" would like to see the elimination of all personal likes or dislikes as far as possible removed from any description. I see what he means, I think. He would like a sort of *Botanical Magazine*, one in contradistinction to that of an enthusiastic gardener. "Is it possible?"

SOLANUM CRISPUM, A BEAUTIFUL CLIMBER WITH PALE BLUE FLOWERS. (See page 54).

I ask. Not yet, for neither classification nor the names of shapes are finally settled—even colour designations are very vague, while, as for texture, nomenclature is still more at sea. When we settle these (and other points) once and for all, and when all of us agree to stand by the result, then, if *nothing else* but this bare list of facts be put after a flower, we will have "Somerset's" "perfect catalogue." Oh, but how cold it will be! and will everyone think it perfect even then? I fear not. What a Herculean task the would-be purchaser will have if he has to select "all on his very own" with no hand to help or star to guide! Imagine him constructing each one with compass and pencil and paint-box, or even forming mental images of their looks. I fancy very soon the "perfect catalogue" will be on the road to Jericho and the would-be selector will find himself disconsolately humming

"It's a long, long way to Tipperary,
It's a long way to go."

What, too, of poor "J. R.," who pleaded in THE GARDEN of January 2 for light on what varieties are calculated to withstand best the rigours of the cold North! He would not get much help. In fact, it occurs to me that if all catalogues were on the lines of "Somerset's" "perfect" one, it would really be grand for writers for the Press. There would be such a lot of things everyone would want to know, and "J. R.'s" would spring up on all sides. But I must cease my funning, or else I shall get rapped over the knuckles. What can I recommend in the way of

Daffodils Suitable for the North? To begin with, I will *not* include any one of the three that "J. R." mentions—King Alfred, Ariadne or Homespun. Not one of these is a good garden plant in the way that Emperor and Barrii conspicuous are. It may be that it is not the cold above ground that they so much resent. Probably it is the dry air or the cold, damp soil. I know, for example,

when Mr. E. M. Crosfield utterly failed to grow King Alfred at Wrexham, he sent his stock to the West Coast of Scotland, and there it soon put on a regular Cornish look. Hence, in making up this little selection, I am guided by the knowledge of what I think will "do" anywhere and that can look after themselves, like Emperor. Here it is, for what it is worth. I do not expect everyone to agree with it altogether, for Daffodils are such surprising creatures that one never can be quite sure what they will do next.

The List.—Bernardino, The Fawn, Great Warley, Lady Margaret Boscawen, H. C. Bowles, Red Chief, Occident, Solfatare, Noble, Steadfast, Pedestal, Blackwell, Countess of Southesk, Fairy Queen, The President (Wheadon), Evangeline, Argent, Duke of Bedford, Virgil, Whitewell (it lifted every year), Lord Muncester, Kingsley, Acme, Golden King, Orient, Empire, Hon. Mrs. Francklin and Cygnet. These might be added to, but the above are a fairly representative lot

of varieties, likely to do well anywhere. Is this what "J. R." wants?

Showing Leedsii.—I have had a long and very interesting letter from Mr. Morton, who wants to know how judges judge Leedsii classes now there are so many types, *e.g.*, the Eoster, the White Queen, the Duchess of Westminster, the St. Olaf, &c. He seems to think that the smaller kinds are often valued too highly when "ordinary" and "giant" are in competition, and suggests that an official division should be made by the Narcissus committee. I am very

told him he must keep it on the wall, that the growth on the top of the pergola would help to shelter it, and that this prudent placing would ensure its precious survival. When I visited him two years later, at the end of May, I found it had scorned the wall, had set itself on the top of the pergola, and there rose as a great dome of lilac-coloured blooms, braving the east winds that threw themselves down upon it from the chalk downs. I have now set it in quantity in the coldest shrubbery I possess. The example illustrated on page 53 is one I originally planted against

spikes of blossom more or less freely from June until late September. The Red Valerian is perfectly naturalised in the South of England, and imperfectly so in the Northern Counties and a few places in Scotland. It is usually associated with the sunny side of chalk pits, limestone banks and railway cuttings. It is an admirable subject for a wall garden, and never looks happier than when growing on rocky banks or ruined walls. This plant, botanically known as *Centranthus ruber*, is an old inhabitant of our gardens, and, apart from its value as a wall plant, looks very

THE RED VALERIAN, *CENTRANTHUS RUBER*, VEILING AN OLD WALL.

much disposed to agree, but it would be well to hear other opinions. Readers interested, please write.

JOSEPH JACOB.

SOLANUM CRISPUM.

SOLANUM CRISPUM is a plant which loves to peer over the wall top. I remember some years ago, when I still thought it of a half-hardy nature, planting it on the south wall of a pergola on high ground in Wiltshire. I recommended it to the owner of the garden with some misgiving. I

a wall, but, like the Wiltshire plant alluded to, it rises many feet above the wall and shoots out its great boughs as freely on the north as on the south side. It is, indeed, the north side that is here depicted. H. AVRAY TIPPING in *Country Life*.

THE RED VALERIAN.

EVERY wild flower has its season, and the Red Valerian is at its height of perfection about midsummer. Not that it is a flower of fleeting beauty, for it continues to send up its

handsome when grown in a flower border. The flowers show considerable variation even in the wild state—white, purple, red and crimson all being represented. The crimson form is the most attractive, but it cannot be relied upon to come true from seed, owing to the ease with which the flowers cross with one another. In the case of rocky banks and o'd walls the seed should be sown in spring in the places where the plants are to flower. When once established, self-sown seedlings are quite certain to appear in each succeeding year.

C. Q.

A GARDEN OF EVER-BLOOMING ROSES.

OUR American friends are very fond of the term "ever-blooming Roses," and if it is not quite correct, it serves its purpose to indicate to the reader what are really perpetual-flowering varieties. Naturally, if one possesses but a tiny garden, one desires to obtain as much enjoyment as possible from it; and I would ask, From what plant can we obtain so much delight or such a constant supply of bloom as from the Rose? If we plant Violas, it is true we obtain their sweet flowers over a very long period; but one cannot gather Violas, and one does Roses. Again, if we plant Zonal Pelargoniums, they not only look very wretched after a few showers, but they must of necessity be renewed every summer. So that one must come to the Rose if they would desire the greatest charm for at least seven months—from May to November—and I might even say to Christmas, for it was my pleasure last Christmas to gather quite a nice bouquet of Roses to adorn our table.

Supposing, then, one is able to lay one's garden out to contain a dozen beds for Roses, what kinds shall we plant? I would suggest they should be filled as follows; if possible, allot the largest bed to Hybrid Teas. The varieties named are all so good that it is difficult to say which are the best. Supposing all those named cannot be planted, I would suggest taking them in the order as given. I have called them Groups 1, 2 and 3. Group 1 would be planted in the centre of the bed or at the back of the border, as they are the strongest growers; Group 2 next, and Group 3 on the outer edge. This applies to all the lists given.

Bed No. 1.—Group 1—Mme. A. Chatenay, Lady Pirrie, Pharisæer, La Tosca, Dorothy Page-Roberts and Mrs. A. E. Coxhead. Group 2—Caroline Testout, General Macarthur, Gustav Grünerwald, Prince de Bulgarie, Mme. Ravary, Laurent Carle, Betty, Lady Ashtown, Mme. Leon Pain, Ecarlate, Ophelia, Theresa, Augustine Guinoisseau and Countess of Derby. Group 3—Mme. Jules Grolez, Richmond, Mrs. A. Tate, Mevrow Dora von Sets, Mrs. E. Powell, Countess of Shaftesbury and Old Gold.

Bed No. 2.—Tea Roses: Group 1—Corallina, G. Nabonnand, Peace, Marie van Houtte, Lady Hillingdon, Betty Berkeley, Rosomane N. Thomas, General Schablikine and Comtesse F. Hamilton. Group 2—Sulphurea, Molly Sharman Crawford and Mrs. H. Stevens. Group 3—Mme. Antoine Mari, General Gallieni,

Papa Gontier, Mrs. Sophia Neate or Little Dorrit.

Bed No. 3.—Monthly or China Roses: Group 1—Common Pink. Group 2—Armosa, Irene Watts or Laure de Broglie.

Bed No. 4.—Monthly or China Roses: Group 1—Laurette Messimy. Group 2—Comtesse du Cayla, Mme. E. Resal, Arethusa or Queen Mab. Group 3—Little Pet or White Pet.

Bed No. 5.—Monthly or China Roses: Group 1—Fabvier and Rödhätte. Group 2—Crimson China, Cramoisie Supérieure and

d'Or and Frau C. Walter. Group 3—Eugénie Lamesch.

Bed No. 9.—Group 1—Grüss an Teplitz, a strong grower that requires tying over, or to be transplanted every autumn and pruned to about 18 inches the following spring. Group 2—Merveille des Rouges. This is a grand bit of colour and deserves a bed all to itself.

Bed No. 10.—Single or semi-double Roses: Group 1—Danæ, Adrian Reverchon and Moonlight. Group 2—Queen of Musks.

Bed No. 11.—Single Roses: Group 1—Irish Glory. Group 2—Irish Elegance, Irish Simplicity, Irish Beauty, Irish Fireflame and Alexandra Zarifi. Group 3—Muriel Jamieson and Mrs. W. T. Masses.

Bed No. 12.—Pernetiana Roses, a glorious group with beautiful leathery foliage: Group 1—Cissie Easlea. Group 2—Mme. Edouard Herriot and Willowmere. Group 3—Arthur R. Goodwin, J. F. Barry and Louise Catherine Breslau.

If space permits, I would suggest isolated specimens of the following, either as moderate pillars, as a hedge mingled together, or individually as big bushes: Sylvia, Alister Stella Gray, Bardou Job, Climbing Mrs. Grant, Climbing Lady Ash town, Climbing Richmond, Florence H. Veitch, Gloire de Dijon, Gustave Regis, Papillon, Fellenberg, Longworth Rambler (a bad name, for it does not ramble, but for our purpose is just the sort), Aimée Vibert à fleurs jaune, Lady Waterlow, Birdie Blye and Trier. There are plenty of other sorts, but if all the foregoing can be planted, or only part, I can promise my readers a glorious display, commencing with the Old Pink China on May Day in some parts and closing the year with the same Rose and even some of the others. To encourage a continuous blooming, the beds should be dug deeply and the plants obtained on seedling Briar or on their own roots, as Roses on the cutting Briar are not nearly so perpetual as those on the seedling Briar. Then, again, summer pruning should be resorted to; that is to say, if the blooms are not culled much for the house, the growths that

bear them should be cut to good sound eyes, not too far back. Old blooms when faded should be removed, also any seed-pods that do form ought to be gathered when quite small, as their development naturally puts a considerable tax on the vitality of the bushes. The beds should be mulched in June with very rotten manure or a little peat moss, and occasionally forked up prior to this. If the season is dry, good liberal waterings will be advisable, especially on a gravelly subsoil. I also advocate a replanting of all the beds every third or fourth year.

DANECROFT.

A PHOTOGRAPHIC STUDY OF ROSE MME. RAVARY, A VARIETY THAT FLOWERS OVER A LONG PERIOD.

Charlotte Klemm. Group 3—Leuchtfeuer and Feuerzauber.

Bed No. 6.—Polyantha or Pet Roses: Group 1—Katherine Zeimet. Group 2—Jessie. Group 3—Jeanne d'Or. The first and last are white, the middle one red. If preferred all of one colour, of course either can be planted alone.

Bed No. 7.—Polyantha or Pet Roses: Group 1—Orleans Rose. Group 2—Annie Müller, Mrs. Cutbush and Ellen Poulsen. Group 3—Maman Turbat.

Bed No. 8.—Polyantha or Pet Roses: Group 1—Canarienvogel. Group 2—George Elger, Perle

ST. DABEOC'S HEATH.

STRICTLY speaking, this charming little low-growing evergreen shrub is not a Heath, but very closely allied to the family, thriving under similar conditions to the hardy Heaths. It is wild in Ireland, and is often known as the Irish Heath, its botanical name being *Daboecia polifolia*. It is strange that such a charming little flowering shrub as this is so seldom met with in gardens, as it is not difficult to grow, providing the soil is well drained and a good proportion of coarse peat is added before planting is done. For the front part of the shrub border, or even for filling a lawn bed where a low-growing, permanent plant is required, the Irish Heath, or one of its varieties, is excellent. In the case of the shrub border a good-sized colony should be planted, as this will prove far more effective than a solitary specimen. It forms a tuft-like shrub about a foot high, and its rather small, droop-

there appear to have been few attempts to secure distinct and new varieties of it. It is possible that most of those who grow this sweet-scented evergreen shrub prefer it in its original and simple form, yet there are several deviations from the normal that have their own peculiar charm and usefulness. One of these is the so-called golden-leaved Rosemary (*Rosmarinus officinalis aurea*), a counterpart of the type, except that the leaves have a golden tint. The most useful variety of all is *prostrata*, a half-creeping plant, which has rather smaller leaves than the type and is excellent for the rock garden. Planted above a large mass of stone, the growths will soon overhang it and form a fragrant bank of green. A very erect variety which makes fine specimen bushes for isolated positions is that known as Miss Jessop's Upright Rosemary. It makes a much better shaped plant than the original shrub, and yet has the fragrance and vigour of its parent.

and foliage some 9 inches to 12 inches high, and during the dull days of November produces its curious Pea-shaped flowers in abundance. The wings of these are light purple and the keel greenish yellow, a combination that is much more effective than one would imagine. The leaves are about two inches long, lance-shaped, and of a rather leathery texture. There is a variety known as *grandiflora*, which has rather larger flowers of creamy white colour. A well-drained position, with some protection from biting east and north winds in spring, are all that this dainty little shrub calls for in the way of special treatment. H.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Brasso-Cattleya Cliftonia albens (Cattleya *Trianae* alba × Brasso-Cattleya Queen Alexandra).

— The flower is of exceptional size and exquisite purity; an all-white flower, indeed, save for a suffusion of pale golden yellow in the back of the throat. Apart from purity, the exquisitely deeply crimped lip appeals, the side frilling being very beautiful and pronounced. Wedded to these is a flower of the largest size. A novelty of distinction and merit.

Dendrobium Triumph (*D. dalhousieanum* × *D. thyrsiflorum*).

— Without doubt the most remarkable Orchid novelty for many a day, and withal one of the most distinct, as might well be imagined from the intercrossing of two such dissimilar species. The greater leaning, both as regards the length and form of the pseudo-bulbs and the manner of flower production, is towards the first-named parent. The exhibited plant bore five pseudo-bulbs, and was probably six years or so old. The smallest bulb was of the length of a Cedar-wood pencil, the flowering one approximating to 4 feet. The widely spreading flowers are of purest white, and characterised by a huge maroon crimson blotch on either side of the lip, as in the

first-named parent. These remarkable novelties were exhibited by J. Gurney Fowler, Esq. Brackenhurst, Pembury, Kent (gardener, Mr. J. Davis).

Solanum ciliatum.—Although the fruiting shoots of this plant did not receive an award from the floral committee, they are sufficiently rare in this country to call for special notice. The accompanying illustration gives a good idea of the spiny stems and shape of the fruits. The latter in size and appearance closely resemble those of small scarlet Tomatoes. The plant is a native of Porto Rico, and Miss Willmott informs us that it makes a glorious bush in her Italian garden. Grown outdoors in her garden at Warley, however, the fruits have failed to colour. The fruiting sprays, which created considerable interest, were imported from Italy and shown by Messrs. R. Felton and Sons, Hanover Square.

The above were shown on the 19th inst., when the awards were made to the Orchids.

FRUITING SHOOTS OF *SOLANUM CILIATUM*, A LITTLE KNOWN PLANT FROM PORTO RICO.

ing, globular flowers are usually present for several months during summer. The colour of these is dull rose or red. Some nurserymen, however, offer a pure, glistening white-flowered variety known as *D. polifolia alba*, and this is a delightful little shrub. *D. p. bicolor* produces both red and white flowers, but the effect of these is not pleasing. March is a good time for planting the Irish Heath, and all who appreciate unusual shrubs should find room for a plant or two in their gardens.

LITTLE-KNOWN FORMS OF THE ROSEMARY.

ROSEMARY is one of those plants which were cultivated in the earliest English gardens, and when we consider this fact it is surprising that more varieties of it have not been brought into existence. It has always been a favourite, yet

The end of February is a good time to plant these old-fashioned shrubs, but to ensure success a well-drained site should be chosen, and the soil, if not already so, must be made of a sandy character. Given these and a sunny spot, the Rosemary will thrive for many years without attention.

A USEFUL ROCK GARDEN SHRUB.

DURING the late autumn months, when most of the plants in the rock garden are looking their worst, much interest may be derived from a few low-growing shrubs, providing these are selected with proper care and planted judiciously. One of the best that I know of for the purpose, and one that is not difficult to grow, is *Polygala Chamæbuxus*. This is by no means a common shrub, but were it more widely known I am sure that it would find a home in every well-appointed rock garden. It quickly makes a neat tuft of shoots

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Late Peaches.—The pruning of these must not be longer delayed, or there will be danger of the buds being damaged. To keep old trees well furnished with fruiting wood, it is sometimes necessary to remove some of the old branches. Guard against overcrowding, as there is nothing gained by leaving too much wood in the trees. When pruned carefully, wash the whole of the wood with a mixture of soft soap and sulphur before tying the trees to the trellis. If scale is present, a quantity of lime should be added to the mixture.

Fruit Trees in Pots.—Where a house can be devoted to the growing of pot fruit trees, it is doubtful if any other method of growing fruits under glass gives greater satisfaction. For the purpose of supplying fruit for table, the greatest consideration should be given to Peaches, Nectarines and Plums. These may all be grown successfully in the same house, and if the right varieties are chosen, a supply of high-class fruits may be had from the same house for at least two months. The trees which were repotted last autumn should now be ready to start, but before bringing them indoors do what little pruning is necessary and clean them with an insecticide. For the first week or two, fire-heat must not be used.

Plants Under Glass.

Euphorbia pulcherrima.—As the plants pass out of flower gradually withhold water, eventually placing them under a stage in a house having a temperature of about 50° to rest till they are required again to make cuttings for another season.

Calanthe Veitchii.—When the flower-spikes have been cut, the bulbs must be placed closely together on a shelf near to the glass in a temperature of 55° or 60°. If space is limited, shake out the soil from the bulbs and pack them closely together in boxes, covering the roots with sifted leaf-soil or fibre.

Hydrangea hortensis.—A batch of plants may now be introduced into heat. First overhaul them, cutting away weak, useless wood; and if they do not need repotting, give them a surface-dressing of some rich material. Cuttings rooted last autumn may be potted into 5-inch pots.

Richardia africana.—Plants must be given more liberal treatment in regard to watering and feeding. If necessary, some of the strongest plants may be hastened into flower by placing them in a warmer house.

Sweet Peas in Pots.—The plants which were raised last autumn should now be ready for potting into their flowering pots. Give them a rich compost and pot firmly. Keep them growing quite close to the glass and give fire-heat sparingly.

The Flower Garden.

Lawns.—The appearance of lawns will be greatly improved by rolling them, but this must only be done when they are in a suitable condition. Where moss is troublesome, an effort should be made to destroy it. A great deal may be got rid of by carefully raking the lawn with a small, sharp-toothed rake, afterwards applying a dressing of lawn sand. Where the grass is in poor condition, a dressing of some suitable manure should be applied as soon as it can be seen that growth is on the move. If new lawns are contemplated, the ground should be prepared at once, so that it may thoroughly settle down before sowing the seed or laying the new turf. Any alterations, levelling or draining of lawns must also be finished as soon as the weather will allow.

The Rock Garden.—Some of the larger-growing plants need carefully cutting back at intervals, or they will overgrow smaller subjects. In some cases it may be better to remove them altogether and replace them with young plants. Numerous bulbs may be planted in the rock garden for a spring display. Anemones, Snowdrops, Narcissi, Muscari, Chionodoxa, Scillas and some of the dwarf-growing Irises may all be effectively employed on the rockery.

The Hardy Fruit Garden.

Peaches and Nectarines.—The pruning and training of these must be done before there is danger of damaging the buds. First go over the trees and cut out any old branches which can be spared. An old, unsightly tree may often be much improved both in appearance and productiveness by a careful thinning of the old branches. Young trees which have made over-strong growth should be lifted and root-pruned, and when replanting see that the roots are not buried too deeply. It is a good plan to have the rooting medium a little above the natural level.

The Kitchen Garden.

Peas in Pots.—If a cool house, such as a Peach-case, is available, the first supplies may be obtained from plants grown in pots. The seeds may be sown in 6-inch pots and the seedlings potted on into 10-inch, or they may be sown in the larger size now. Give them a good rich compost and pot firmly. A dwarf variety, such as Little Marvel, must be used for this purpose.

Potatoes.—If the soil is in suitable condition, the tubers which have been prepared for growing in pots may be planted now. Plant them in drills about two feet apart and 9 inches between the tubers. No water will be required until the plants have made 2 inches or 3 inches of growth. Encourage them to grow sturdily by carefully admitting air whenever the weather will allow.

Forcing Vegetables.—Place quantities of Asparagus, Seakale and Rhubarb into the forcing quarters at regular intervals. Seakale and Rhubarb may be covered with boxes and litter outdoors to follow the indoor supplies. A supply of Mustard and Cress can easily be kept up by sowing in cutting-boxes every few days.

Horseradish.—An out-of-the-way corner in the garden is suitable to grow this useful vegetable, but the ground must be deeply dug for its reception. The roots may be lifted now and replanted in rows a foot apart.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Fruit Under Glass.

Vines.—When young Vines are required, either for planting or growing in pots, this is a good date to start propagating by inserting eyes. Each eye should be inserted in a separate piece of turf and plunged in a close propagating-case. Well-ripened wood of medium size is the best from which to select the eyes.

Planting Young Vines.—The formation of the borders in which these are to be planted should be completed. The young Vines, which have been already cut back to two eyes, will be found to start much more readily and strongly if the roots are spread out in shallow boxes of soil and placed on the hot-water pipes. See that the Vines do not want for water until they are finally planted out in April in their permanent quarters.

Peaches and Nectarines.—Examine the borders occasionally in houses where trees are resting. Excessively dry borders are very often the cause of much bud-dropping and uneven setting.

Pot Figs.—The strongest growths must be pinched when they have made six or seven leaves. This operation should be extended over several days, so that the entire plant is not checked at once. Although Figs succeed best with a restricted root-run, they must have constant applications of liquid manure, also occasional top-dressings.

The Kitchen Garden.

Parsley.—If, owing to severe weather, the supply has become exhausted, some plants had better be lifted and planted indoors. Very little heat will be required to make them produce some fresh young leaves. Make a sowing in boxes to have plants ready for planting out early in May.

Manuring.—Take advantage of all opportunities, such as frosty mornings, to get manure carted or wheeled on to all vacant plots which are to be dug.

Pea Stakes.—Attention to these can be given while the ground is unfit for working on. The

life of Pea stakes is generally short, so that they need to be replaced, if not annually, every alternate year. When suitable Pea stakes cannot be obtained, large-meshed wire-netting, such as is used for sheep, will be found a good substitute if used double and supported by stout stakes.

Plants Under Glass.

Amaryllis.—To keep up a succession of flowers, small batches of plants must be brought into heat. For the earliest lot, select plants that will not require repotting this season. These plants are very subject to attacks of mealy bug, and must be looked over carefully before starting. The scales of the bulbs offer an excellent hiding-place while the plants are dormant.

Ferns.—It is not a good practice to repot all Ferns each year, as most of them produce their best fronds after they become pot-bound. Still, some will need renewal, and should be attended to before the young fronds commence to unfold.

Clerodendron fallax.—Although this brilliant stove-flowering plant may be propagated from cuttings, it is more simple and better to raise it from seed. A batch of it sown now will flower during July and onwards. Being very subject to attacks from red spider, the plants throughout their growth must be constantly syringed as a prevention. Besides, this plant revels in a humid atmosphere with plenty of heat.

Streptocarpus.—Cuttings which were inserted five to seven weeks ago are ready to pot. Three and a-half inch pots will be large enough, and for this potting use a fairly light compost. Keep the cuttings close for a few days, and spray lightly when the weather is bright. If green fly is troublesome, a fumigation should be given when the plants have recovered from the check of potting.

Cordylines are easily raised from seed, and it is a good plan to raise a number annually, so as to have them all sizes for decorative work. Being less tender than Palms, they are very useful during the winter season.

Crotons.—Cuttings should now be taken and plunged in a close propagating-case in the stove. Well-furnished tops can be "rung" and moss tied around, into which they quickly root and are then ready for potting.

The Hardy Fruit Garden.

Winter Spraying.—The use of alkali must soon cease for this season, as it is dangerous to swelling buds. Unless fruit trees are very bad with lichen and insect pests, it will be found frequent enough if applied every alternate year. Too free a use of this wash is apt to injure the bark and buds even while dormant.

Grafting Preparations.—Scions of Apples intended to be used for grafting later on should be carefully labelled and heeled in the soil behind a north wall.

The Flower Garden.

Cosmos.—Unless sown early, this annual does not flower freely until far into the autumn; often it is cut down by frost when at its best. It should not be planted in too rich a soil, or an abundance of gross growth will result, with very few flowers. The seed germinates rapidly in a warm greenhouse, and the young plants should be potted singly as soon as ready to handle.

Begonias.—Both fibrous and tuberous rooted Begonias should be sown now in seed-pans. The seed, being very small, must be carefully sown on the surface of very fine soil, and ought not to be covered. Place sheets of glass over the seed-pans, and put them in a temperature of 60°.

Montbretias.—Frames containing Montbretias should be ventilated freely to try to retard the young growths. Protect them only during severe frost. These plants respond to very liberal treatment, and are well worth any extra time and trouble bestowed upon them. The beds or borders they are to occupy should now be prepared by digging in a good quantity of farmyard manure, adding a dusting of bone-meal at the same time. The following varieties are all free flowering and handsome: George Davison, Star of the East, Prometheus, Westwick, Messidor, Hereward, Germania, aurantiaca, carmineus, Ernest Davison, Oriflamme and Gold Mine.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

DAFFODILS FOR THE GARDEN.

I FEEL that I must give expression to my sympathy with "J. R.," who tells us in the issue of January 9, page 22, how he opens his GARDEN every week in the hope of finding an article on his favourite the Daffodil, and how often he is disappointed; for I scan its pages eagerly each week for some "Daffodil Notes" myself. I heartily endorse his appreciation of the Rev. J. Jacob's articles. They always contain useful information, and are so charmingly written that reading them is like enjoying a friendly and intensely interesting chat.

"J. R.'s" further remarks raise one or two points in my mind which I should like to mention. If there is a variety for which you have a particular liking which does not thrive with you for the first two, three or even four years you have it, do not give up hope or throw it away, unless it is known to be a bad doer everywhere. Keep it, and very likely you will find that it will presently acclimatise itself and "settle down" to grow quite well. Ariadne has been with me a striking example of "settling down." A few rather sickly bulbs of it were given me, I think, eight years ago. For three or four years it was a wretched thing, hardly knowing whether to live or die; then it began to improve, and the last two seasons it has been splendid, growing with much vigour and rapid increase. When lifted last summer, the bulbs were full-sized, plump, hard and clean. Its foliage, however, is naturally, even in perfect health, of a slightly yellower and washier green than most.

Homespun is a lovely show flower and a rapid increaser, but I should say it is not a first-rate garden plant anywhere. It has never been sickly with me, but it is not a vigorous grower. I saw it in a garden close to the sea with a grand climate, where King Alfred simply romps, no better than I have it myself. Coming to King Alfred, we have a peerless flower over which it is well worth taking a lot of trouble. In my opinion there is no golden self Ajax within reach of ordinary purses which can for a moment compare with it, and I scarcely think I have seen anything among the finest and newest seedlings which really excels it in actual beauty. It is a noble plant, while the bloom has exceptional substance, making it extraordinarily lasting as a cut flower. Its form is perfectly graceful, its texture velvety and refined, and its glorious colour of wonderful purity. If you hold a bloom up directly facing the sun, you will, if you look carefully, see a beautiful sort of luminous halo on the reflexed brim of the trumpet, while the superbly serrated crown, together with the colour, gives the flowers when seen in a bunch or growing in a mass a regal opulence of splendour that is unrivalled. I was going to add that its stem is the envy of all other Daffodils, but probably "J. R." will not agree with that! Doubtless its great height has disadvantages in wind, but the distinction it lends to the plant and the advantages of such a stem for cutting more than outweigh them, and make it well deserving of special consideration in the way of an extra well-sheltered position.

Now for my experience with His Majesty. My first bulb of it was a nice, clean, strong one from the Riviera-like climate of Cork, in comparison with which the "Black North" must have felt

very inhospitable. The first two years it did splendidly, then suddenly it went very sickly, though still increasing; but the bulbs were small and sickly looking. Some seemed stronger than others and soon recovered; but all, or practically all, became quite healthy again, and now increase rapidly with perfectly healthy foliage and abundance of blooms, seeding very freely. A few are just appearing above the ground as I write, and look stronger and bigger than ever. A few tiny and very sickly bulbs—almost dead, in fact—of King Alfred came to me some years ago. I planted them in a carefully chosen position. I fancy the worst did die, but a number came up, and their growth suggested the very last stages of sickness. As they looked no better at the end of three years, I made up my mind to throw them away. When I dug them up, I found that although they had gained scarcely anything in size, they were distinctly cleaner and more healthy looking. I then replanted them in a new position, and in two years several had attained flowering size and did flower last spring, while all looked strong and healthy, and will this season, I expect, be quite equal to the best of my stock.

I believe there are some places where King Alfred will not grow; still, I should recommend "J. R." to give it another trial in as sheltered and warm a spot as he can afford, planting pretty deeply in deeply trenched ground. If the soil is heavy and cold, no doubt it will help greatly if a generous quantity of leaf-mould, wood-ashes and sand be incorporated with it. Personally, I think King Alfred so beautiful that if I could not grow it in any other way I should prepare a bed very carefully and then build a cold frame over it!

If "J. R." wants a stiff-stemmed, small white Leedsii, and not extra tall, let him try Fairy Queen if he does not already know it. The growth is vigorous and rapid of increase; but Waterwitch would not be Waterwitch without that fishing-rod stem and lovely drooping grace. I know it looks untidy in the garden when it is stormy, but cut a bunch of flowers and arrange them lightly in a vase for a high shelf in your room, and you have nothing like it for graceful effect, which will be heightened if you put a jarful of Autocrat near by way of contrast.

County Antrim.

G. L. WILSON.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

IRIS FAILING (W. H. R.).—Though it is the worst season of the year for these plants, the portions submitted are not in a very flourishing condition. In large degree, if not absolutely, we should lay the blame on the heavy clay soil of your district, a condition magnesium limestone screenings would not remedy unless incorporated with the staple at something like fifty per cent. In this proportion it would ensure a much more rapid drainage, and by

precipitating the superfluous water to a lower level, aerate, warm and drain the soil, which is the chief thing needed. Freshly burnt lime, when slaked, at the rate of three bushels per rod of ground would do much the same thing, and would also neutralise any soil acidity, should such exist. The burnt clay (ballast), usually so plentiful in your district, would, if applied at the same rate, also assist in the same way, and leaf-mould, grit or sand would do the same. Should you have the opportunity, try a small experimental bed or patch on the above lines, raising it a foot or more above the ordinary level to facilitate drainage, &c. With increased soil warmth and porosity the plants will do much better. Mid-March is a good time for replanting, and in doing this you only need retain the sectional portion of the rhizome made last year with its complement of roots. The older rootless sections are valueless, and may be discarded. Keep the rhizomes level with the surface soil when planting; do not bury them.

TREES AND SHRUBS.

CAMELLIA OUTDOORS (A.).—You will find Camellia japonica Chandleri elegans a very good pink-flowered kind to use on your wall out of doors. Drain the border well if not naturally well drained, and mix a little peat and leaf-mould with ordinary light loam. Do not overdo the peat, but a little about the roots will be appreciated. A plant can be procured from Messrs. Wm. Paul and Sons, Nurserymen, Waltham Cross, and the best time to plant is late April. Protect the plant at night for a month or so, and for a short time against bright sun at midday. Also be careful to keep it well watered until the roots are working well into the new soil. The most important item is to prevent the old ball of soil from becoming dry.

STANDARD BROOM (A. B.).—It is usual to graft certain kinds of Broom upon stocks of common Laburnum, either quite low down or upon stocks 2 feet to 4 feet high. In some cases Laburnum roots are used for stocks. Such strong-growing Brooms as Cytisus praecox and C. scoparius andreanus are best grafted quite close to the ground or worked upon roots, and look out of place as standards. Such kinds as C. purpureus and C. leucanthus make fine heads when grafted on stocks 2 feet or 3 feet high. To work the stocks in this way, the Laburnums should be established in pots and the grafting be done in a warm greenhouse in late February or March. Use firm shoots for scions, and use either an ordinary side graft or a wedge graft. Lay the plants on their sides in a close propagating-case until the union of stock and scion is complete; then gradually inure to the open greenhouse, and eventually plant out of doors.

THE GREENHOUSE.

VARIOUS GREENHOUSE QUESTIONS (G. B. S.).—(1) In practice this has not been found satisfactory. (2) No. (3) Doubtful if it would. (4) Clematises may be readily flowered in pots of different sizes. For instance, at some of the meetings of the Royal Horticultural Society, well-flowered examples are often shown in 5-inch pots, while, for large specimens, pots 1 foot in diameter may be used. (5) For permanent decoration they would be better planted in a border than grown in pots. At the same time, as Clematises do so well out of doors, we fail to understand why you are building a house for their reception. (6) They would grow up a trellis on the roof very well. (7) They are pruned the same under glass as out of doors. Different sections, however, need different modes of pruning. (8) When Clematises are confined in pots they need good soil, such as three parts loam to one part leaf-mould, and well-decayed cow-manure free from insects. As the pots get full of roots, an occasional stimulant will be beneficial. The border should be effectually drained and contain a couple of feet of good soil. We do not know of any other book on the subject.

VARIOUS QUESTIONS (H. T.).—Pancratiums.—These are essentially stove plants, and many successful cultivators keep them in that temperature all the year round. On the other hand, they are by some given a slight rest after flowering. This has one drawback, inasmuch as if kept somewhat cooler and drier for about a month in order to rest them, the foliage is apt to acquire a yellowish tinge. The best temperature for Pancratiums is, during the winter, a minimum of 60°, rising during the day, with, of course, an increased temperature as the days lengthen and the weather gets warmer. They should flower twice in a year. Where it is intended to rest them, they should for a month be placed in a temperature from 5° to 10° cooler, and given rather less water. Begonia Gloire de Lorraine.—The plants that are going out of bloom should be partially shortened back and placed in a temperature of 50° to 60°. Just enough water should be given to keep the soil slightly moist. In this way the plants will undergo a period of partial rest. Then, early in March they may be put into a structure 10° warmer or therabouts and given more water, at the same time spraying them during bright days. This will lead to young shoots being pushed out, those nearest the base of the plant being the best for growing into large specimens. As soon as they are rooted and potted singly, the young plants should be placed near the glass in order to maintain a healthy, sturdy growth, and plenty of light, heat and moisture given, but they must be shaded from hot sun. Air must be given whenever it is safe to do so. The temperature may range from 60° at night to 20° or so higher in the day. A suitable compost may be made up of equal parts of loam and leaf-mould, with a little sand and dried cow-manure. Good plants may be grown in pots from 5 inches to 7 inches in diameter. During the growing season the plants may be subjected to a temperature of 65° to 80°, and as the pots get full of roots

an occasional stimulant will be beneficial. With the approach of autumn and the flowering season the temperature may be gradually reduced to 55° or 60°. *Dendrobium nobile*.—After the flowers are over, say, in the month of April or May, the plants will then produce new growths from the base of the pseudo-bulbs, and that is the time to repot them if they require it. Fibrous peat and sphagnum moss form a very suitable compost. After repotting, water should be sparingly given till the fresh roots have taken possession of the new material. Maintain a temperature of 65° to 70° by night and a reasonable rise by day. Keep the atmosphere moist, and occasionally spray the plants during bright weather. They must also be kept well watered. When the bulbs are fully developed, they must, in order to ripen them, be gradually exposed to more air and sunshine and a cooler and drier atmosphere. This must not be done all of a hurry, but first allow them to become moderately dry at the root, then remove them to a minimum temperature of 60°, with a little more air. This and gradual exposure to full sunlight will lead to well-ripened pseudo-bulbs. During the late autumn and winter a temperature of 55° to 60° by night, and a little warmer during the day, will suffice. At that time they must be given just enough water to keep the bulbs plump. Then, as soon as the flower-buds are visible, the plants must be removed into a warmer structure to expand their blossoms. *Poinsettia pulcherrima*.—As soon as these have done flowering, the old heads of bracts should be cut off and the plants placed in a structure of 50° to 60°. They should then be kept dry, in order to give them a period of absolute rest. If the plants appear to suffer, a little water may be given them. Then, in April the soft tops may be cut off and the plants taken into a warmer structure, given some water, and be occasionally syringed. This will lead to a great number of new shoots being pushed forth, and when these are about three inches long they make suitable cuttings. If put into small pots of sandy soil and placed in a propagating-case of about 75° they will soon root. As soon as this happens, they must be inured to the ordinary atmosphere of a structure kept at 65° to 70° and shifted into larger pots when necessary. During the summer they may be grown in a cold frame, giving them plenty of air in order to encourage a sturdy growth. With the return of autumn they must be placed in a warmer structure in order that the bracts may be developed without a check. When the plants are growing they should occasionally be given liquid manure *Euphorbia jacquiniæflora*.—As soon as they have done flowering, the long, arching shoots may be shortened back, and the plants given a good light position in the stove, taking care to guard against an excess of moisture. As soon as the shoots are about three inches long, they may be taken as cuttings and inserted into well-drained pots of sandy soil. In a propagating-case, in a temperature of 65° to 75°, they will soon root. Care, however, must be taken that they do not damp off, which, owing to their succulent nature, they are liable to do if kept too close. As this *Euphorbia* is of spare habit, in order to obtain bushy specimens three plants are often put into the flowering pots. They must, during the summer, have plenty of light and air and a temperature of 65° to 80°.

MISCELLANEOUS.

NAME OF PLANT.—*J. Ballantyne, Melrose*.—The specimen of Butcher's Broom (*Ruscus aculeatus*) sent for examination appears to have been taken from a female plant. It is necessary to have plants of both sexes in order to obtain fruit.

NAMES OF FRUIT.—*North*.—Apple, Bess Pool; Pear, Bergamotte Esperen.—*F. W. Ashdown*.—1, Waltham Abbey Seedling; 2, Lamb Abbey Pearmain; 3, Hawthornden; 4, New Bess Pool; 5, King of the Pippins; 6, Scarlet Pearmain; 7, Wyken Pippin.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THE second fortnightly meeting of the year was held on January 19, and was the occasion for an exhibition which, if lacking great extent, certainly was not lacking variety or interest. Much of the latter was due to the hardy plant specialists bringing in their earliest productions; but, even so, there is room for a still greater number of these and other exhibitors to rally to the society's aid and make these gatherings more normal in these abnormal times. Apart from the alpine, which attracted large numbers, retarded Lilies and other plants, epiphytal and hardy Ferns, Carnations in plenty and of high quality, and a brilliant lot of winter-flowering Zonal Pelargoniums were among the features of the meeting. A few nice Orchid groups were staged, and two remarkable novelties—the only ones at the meeting—received first-class certificates. For a description of these see "New and Rare Plants," see page 56.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. G. Woodward, J. Willard, E. Beckett, E. A. Bunyard, H. J. Wright, G. Reynolds, J. Jacques, G. Wythes, Owen Thomas, P. Veitch, W. Poupert, J. Davis, W. Bates and A. R. Allan.

There were no groups of fruit staged, and only one or two small collections of Apples, chiefly of dessert kinds, shown to test keeping and flavour qualities. For this purpose Mr. E. Beckett, gardener to the Hon. Vicar of Gibb, Elstree, staged about a score of sorts, chiefly of well-known and popular varieties.

Messrs. J. Cheal and Sons, Crawley, had a smaller lot of dessert Apples, among which we noted Allen's Everlasting, a rough-looking though fine-flavoured late sort. Brownlee's Russet was also noted. This firm also showed in excellent form their two new culinary Apples *Crawley Beauty* and *Encore*, both of which have gained high encomiums in their own particular sphere.

Mr. James, Manor House Gardens, Ditton Hill, showed fruits raised from a pip of Apple Cox's Orange Pippin, quite unlike that variety in general appearance.

None of the varieties gained an award, though, judged by the entire absence of fruits later, the "testing" plus appreciation would appear to have been universally severe and complete.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Jeremiah Colman, Sir Harry J. Veitch, and Messrs. J. O'Brien, Gurney Wilson, W. H. White, T. Armstrong, A. Dye, J. Charlesworth, S. T. Flory, F. Sander, R. Thwaites, J. E. Snill, C. H. Curtis, W. Cobb, F. M. Ogilvie, R. A. Rolfe, F. J. Hanbury, W. Bolton and C. J. Lucas.

Orchid groups were not numerous, though some choice specimens were shown. The most extensive group was that of *Cattleya Trianae* alba *Maggie Raphael*, from Messrs. Armstrong and Brown, Tunbridge Wells, and of this alone some three dozen well-flowered examples were staged. Others of merit in the group were *Miltonia bleuana*, *Lycaste Bella*, *Cypripedium lathamianum* Rex, *Brasso-Cattleya Veitchii* and *Masdevallia triangularis*. *Silver Flora* medal.

Messrs. Stuart Low and Co., Enfield, had a charmingly flowered example of *Miltonia Phalaenopsis*, which is rarely seen in such profusion or beauty; the lovely orange-blotched *Dendrobium wardianum*, *Laelia anceps roeblingiana*, in company with *Cypripedium* in variety and a batch of *Odontoglossums*, among which *O. Artemis* was very attractive. *Silver Banksian* medal.

Messrs. J. and A. McBean, Cooksbridge, had quite a series of *Cymbidiums*, whose tall, arching racemes of quaintly formed flowers are very striking at this time. *C. gottianum*, *C. Alexander* and *C. Schlegelii*, the latter of pinky hue, were the best of those staged. All are beautiful, ornamental, and of considerable utility in winter-time. *Cattleya alba Maggie Raphael*, the dark *Odontoglossum keighleyense*, *Laelia anceps alba*, *L. a. Schröleri*, and *Sophro-Cattleya November*, rich dark varieties, were, with *Cypripediums*, others in the same group. *Silver Banksian* medal.

Messrs. Sander and Sons, St. Albans, also received a *Silver Banksian* medal for a choice collection, including *Dendrobium aureum*, *Laelio-Cattleya Trimyra* (of yellowish orange tone), *Lycaste macropylla* (red sepals and petals), *Cymbidium Holfordi*, the white, yellow-crested *Ceologyne mooreana*, *Cypripedium nitens* Sander's variety, *C. callosum* Sander's, and *Odontodia devossiana* (whose abundantly flowered racemes were very telling). *Odontoglossum crispum harryanum* was also very fine.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Druery, E. A. Bowles, W. J. Bean, B. Crisp, G. Reuthe, C. E. Pearson, A. Turner, C. Dixon, J. Dickson, W. P. Thomson, Charles E. Snea, W. A. Bilney, J. W. Barr, F. W. Harvey, J. F. McLeod, J. Hudson, R. C. Reginald Neville, C. Bick, W. Howe, J. Jennings, T. Stevenson, H. J. Jones, E. H. Jenkins and G. Paul.

Messrs. Barr and Sons, Covent Garden, W.C., showed boxes of alpine and early bulbous flowering subjects, among which were noted a delightful lot of *Narcissus Bulbocodium monophyllum*, *Sternbergia fischeriana*, *Galanthus Elwesii* (more beautiful and robust than usual), *Anemone blanda taurica*, *Adonis amurensis*, early flowering *Cyclamens*, together with Christmas and Lenten Roses in plenty and rather nicely flowered.

Messrs. Stuart Low and Co., Enfield, had quite a sumptuous lot of Carnations of good quality, imposingly arranged. A central stand of Gorgeous, perhaps the finest cerise of to-day, contained some ten dozen well-developed flowers, quite a feature in itself. Others of note in the group were Mrs. Mackay Edgar (pink), *Satin Robe*, *Enchantress Supreme*, *Princess Dagmar* (crimson), Mrs. C. F. Raphael, *Snowstorm*, together with vases of seedling *Perpetual Malmaisons* and others in mixture. Ornamented by sprays of *Asparagus Sprengeri* and Ferns, the group was a highly attractive one. *Acacia platyptera*, together with a variety of *Cyclamen* in pots, were also on view. *Silver Banksian* medal.

The Misses Hopkins, Shepperton-on-Thames, showed alpine in boxes, with coloured *Primroses* and other plants. *Tussilago fragrans* was also on view.

Messrs. R. F. Felton and Son, Hanover Square, had a remarkable exhibit of fruiting branches of *Solanum ciliatum*, a shrubby species as shown, whose reddish scarlet fruits are highly ornamental, the largest after the form of a small Tangerine Orange. To the accompaniment of *Ruscus racemosus*, *Pittosporum Colensoi* and *P. undulatum* the group was a great attraction. *Solanum ciliatum* is a native of Porto Rico. It should be noted, however, that Nicholson describes it as a "greenhouse annual," which the above hardly appeared to be.

Mr. James Box, Hayward's Heath, showed boxes of alpine, containing such as the early *Cyclamen*, *Shortia galacifolia*, *Saxifraga burseriana*, a very charming lot in good flower and the first display of the year. *Marrubium sericeum*, *Erica mediterranea hybrida*, the new *Primula malacoides robusta*, *Erica codonodes*, *Primula Julise* and *Hamamelis arborea* were others of the earliest flowers of the year.

Messrs. H. B. May and Sons, Edmonton, displayed a table of epiphytal Ferns, a large number being of the highest interest. These included such as *Polypodium piloselloides*, *P. vacinifolium album*, of glaucous tone with brownish rhizomes; *P. lycopodioides*, *P. percussum*,

P. salicifolium, *P. repens*, *Davallia pycnocarpa*, *Drymoglossum piloselloides*, *Asplenium obtusolobum* and *Davallia rufo*, of which a 3-foot-high specimen was shown. These were interspersed by other Ferns in variety, *Nephrolepis* and *Gymnogrammas*, all being of equal interest. *Silver-gilt Banksian* medal.

Messrs. W. Wells, Limited, Merstham, showed a stand of *Carnation Pink Sensation* and the winter-flowering *Antirrhinum Nelrose*, which is very beautiful.

Messrs. T. S. Ware, Limited, Feltham, displayed a collection of alpine in pans, not a few already giving indications of flowering. Of these, *Saxifraga Frederica-Augusta*, *S. Grisebachii*, *S. burseriana Gloria*, *S. b. tridentata longifolia*, *S. Faldonside*, *S. apiculata alba*, together with *Lenten Roses*, *Iris alata*, *Lithospermum rosmarinifolium* and *Iris stylosa*, were very beautiful. *Bronze Flora* medal.

Mr. L. R. Russell, Richmond, exhibited a table of pot shrubs and decorative subjects generally, such things as *Pyraecantha* (*Cotoneaster*) *angustifolia*, *Garrya elliptica*; *Pernettyas*, *Prunus triloba*, *Skimmias*, *Hamamelis arborea*, *Rubus leucodermis* and *Eurya latifolia variegata* being noted. *Silver Banksian* medal.

Messrs. William Cutbush and Sons, Highgate, N., displayed many fine vases of Carnations, of which the new pink *Lady Inge* was in strong force. It is of a most beautiful shade. *Carola*, crimson; *White Swan*, Mrs. L. D. Fullerton, fancy; and *Marmion* were other good sorts. In a hardy plant exhibit adjoining, *Iris Histro*, *Hepaticas* in variety, *Saxifraga burseriana*, *Galax aphylla* and *Daphne Dauphinii* were noted. Sprays of *Zonal Pelargoniums* were also staged. *Silver Banksian* medal.

Mr. G. Reuthe, Keston, Kent, showed, as usual, an interesting lot of things, both alpine and shrubs. Of the former, the *Saxifragas* were the chief, and of these there were many choice kinds, of which *S. Grisebachii* and *S. burseriana* were already prominent in flower. *Hepaticas*, *Cyclamen Atkinsii purpureum* (a richly coloured sort), *Iris Histro*, hardy *Heaths* and *Snowdrops* were also good. The yellow-flowered *Berberis Bealii* and *Garrya elliptica* were excellent. *Bronze Banksian* medal.

Mr. Amos Perry, Enfield, had a table of hardy Ferns, chiefly *Polystichums* and the finer *Crested Hart's-tongues*. The former included the handsome *P. angulare divisilobum*, *productum* (with dense, flattish fronds and finely cut pinnae), *P. a. multilobum densum*, *P. a. pericristatum* and *P. a. divisilobum capitatum*. The best *Scolopendriums* were the *ramo-cristatum* forms, though all are good now by reason of their dark green, shining fronds. *Silver Flora* medal.

Mr. Clarence Elliott, Stevenage, had a neat rockery exhibit associating colonies of choice alpine with miniature rock shrubs. *Burser's Saxifrage* in one or more forms was in great force, the compact tufts bristling with buds and expanding flowers. *Snowdrops*, early *Cyclamen*, *Iris alata*, *I. stylosa* (unguicularis), very beautiful, and *Thymus carnosus* were also noted. One of the most distinct of the rock shrubs was *Juniperus tanacetifolius*, whose long, attenuated, horizontally inclined, plume-like growths command attention at once.

Messrs. J. Cheal and Sons, Crawley, arranged an exhibit of rockwork in conjunction with alpine, coniferæ and berry-bearing shrubs, the work neatly and artistically done. Of the alpine, *Saxifraga Boydii alba*, *Anemone blanda*, *A. b. alba*, and some fine *Iris histrioides* major were noted; while *Hamamelis*, hardy *Heaths*, *Pernettyas*, and the distinct and beautiful *Pyraecantha* (*Crataegus*) *angustifolia*, full of orange-coloured fruits, were also seen. The latter was a feature in itself. It was very charming.

Messrs. Cannell and Sons, Eynsford, Kent, again showed a remarkable collection of winter-flowering *Zonal Pelargoniums*, some three dozen vases of brilliant trusses being staged. This and a collection of equal size and merit staged by this firm on the 5th inst. constitute, we believe, a record for quality and quantity in January, and we speak from the experience of a quarter of a century of these fortnightly gatherings. The arrangement was the same as before, the trusses graced by light Palms and interspersed by *Primula malacoides*. The most brilliant were *Scarlet King*, *Maxime Kovalevsky*, *Prince of Orange*, *Helen Countess of Radnor* (rosy cerise), *Mars* (crimson) and the fine salmon pink *Barbara Hope*.

Messrs. Waterer, Son and Crisp, Bagshot and Twyford, arranged a nice rockwork exhibit, in which *Snowdrops*, early *Crocuses*, *Winter Heaths*, *Iris Histro*, *Cyclamen ibericum*, *Primula megacaulis*, *Hamamelis* and *Pyraecantha* (*Crataegus*) *angustifolia* combined with good effect.

Messrs. Wills and Segar, South Kensington, S.W., filled a long table with well-flowered groups of retarded Lilies, chiefly *Liliums speciosum* and *longiflorum* in variety. *Spiraeas*, also from retarded examples, were very good. In addition, the giant white and salmon coloured varieties of *Cyclamen latifolium*, which were exceedingly well flowered, call for special remark. Ferns and Palms were associated with the above. *Silver Banksian* medal.

Messrs. Allwood Brothers, Hayward's Heath, displayed a charming lot of Carnations, the fresh flowers of particularly high quality for January. Mary Allwood, as usual, was very fine, though we were more than struck by the pronounced Clove fragrance of *Bishton Wonder*, a sort of nondescript fancy variety—we say it in no derogatory sense—that for this attribute alone should find favour with all. *Champion* (scarlet), *Queen Alexandra* (pink), *Fairmount* (heliotrope), *Wivelsfield White* and *Salmon Enchantress* were others of special merit. *Bronze Flora* medal.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ELECTION OF ANNUITANTS.

THE seventy-fifth annual general meeting of the above Institution was held at Simpson's Restaurant, Strand, London, W.C., on Thursday of last week, Sir Harry J

Veitch, F.L.S., presiding, supported by Messrs. Arthur Sutton, George Monro, P. C. M. Veitch, J. Hudson, Owen Thomas, W. Icton, H. F. Barnes, D. MacDonald, D. Inganells, F. Dimmock, F. G. Frogbrook, R. J. Cuthbert, and others. After the notice convening the meeting had been read, the minutes of the last annual general meeting were read, approved and signed. The seventy-fifth report and balance-sheet were next read.

The following are the most important points from the committee's report:

"The charity was founded in 1838, and has, during its existence, distributed in permanent and temporary assistance upwards of £160,000; and at no other period of its history has it done so much to assist the necessitous and suffering among unfortunate members of the horticultural community—gardeners, market gardeners, and nurserymen and their widows—as in the year under review.

At the beginning of 1914 there were no fewer than 265 persons on the funds—150 men and 115 widows, elected to annuities of £20 and £16 respectively for life. During the year twenty-three of that number died, eleven men and twelve widows. Of the former, seven left widows, who, being eligible and deserving, were placed on the funds without election to receive the widow's allowance of £16 a year, in accordance with Rule VII., D., and the committee now recommends an election this day of fifteen persons from an approved list of sixty-two candidates. Sensible as the committee is of the urgent needs of the many who are appealing for aid, it feels that it cannot, in view of the financial uncertainties in the immediate future, with prudence incur further liability by electing a larger number of the deserving applicants, much as it would like to do so.

The Victoria Era Fund and the Good Samaritan Fund have continued to be the means of much benefit and comfort in the past year, a sum of £260 15s. being given from the first-named fund to thirty-seven of the unsuccessful applicants awaiting permanent aid, and who had formerly been subscribers, in amounts *pro rata* to the length of time they had subscribed; and from the Good Samaritan Fund £216 was granted in various sums as temporary relief to forty-one applicants—subscribers and non-subscribers—whose cases were of a particularly distressing and pathetic character. It would be difficult to over-estimate the benefit conferred by these two funds, more particularly, perhaps, the latter, which enables the committee to give immediate assistance in cases of urgency and need. Unfortunately, while the amounts derived from the incomes of both these funds are limited, the applications for help are ever increasing. Any special contributions, therefore, for either will be most gratefully welcomed.

The committee has again to acknowledge the kindness of the following noblemen, ladies and gentlemen in opening their gardens to the public for the benefit of the charity: The Right Hon. Earl Beauchamp, the Right Hon. Lord Northbourne, Mary Countess of Ilchester, the Lady Wange, the Lady Battersea, Sir Frank Crisp, Bart., LL.B., J.P., C. W. Dyson Perrins, Esq., Roger J. Corbet, Esq., and Ernest J. Wythes, Esq.

To the organisers of successful concerts at Liverpool, Altrincham, Leyton and other places, as well as to the George Monro, Limited, Concert Committee, cordial thanks are tendered.

The committee refers with gratitude to the generosity of Mr. James Sweet, V.M.H., a warm supporter of the charity for many years, who, in addition to his usual liberal yearly gifts, gave a special donation of £500, and to his influence and interest the committee is also indebted for a legacy of £500.

The committee would also mention the kindness of Messrs. Arthur W. Sutton, V.M.H., and George Monro, V.M.H., for again providing a year's allowance to two unsuccessful candidates, who, it need scarcely be said, are deeply grateful.

The several auxiliaries (Bristol and Bath, Worcester, Devon and Exeter, Wolverhampton, Berkshire, Reading and District, and Liverpool) continue to be a source of much support to the Institution, and the committee again offers its sincere thanks to the honorary officers for their greatly valued services and interest."

The financial statement shows that the Institution is in a thoroughly sound condition, but, naturally, much more money is needed to assist all deserving candidates.

In moving the adoption of the report, Sir Harry J. Veitch said the committee were very grateful for the help they had received from subscribers during the year, but were very sorry that they could not ask subscribers to elect more than fifteen candidates. It was, however, at a time such as this, necessary to look to the future. The committee must keep faith with those annuitants already on the funds. They were expending the full amount yearly available from the Good Samaritan and Victoria Era Funds, which enabled them to give temporary assistance to deserving cases. The death-roll among subscribers had been heavy during the year, but he hoped others would come forward to fill their places. The auxiliaries had done good work, for which the committee were very grateful. The proposal was seconded by Mr. W. Icton, and carried unanimously.

Mr. Arthur W. Sutton, in proposing the re-election of Sir Harry J. Veitch as hon. treasurer of the Institution, paid a fine tribute to his work in the past. He had been privileged to propose this resolution for many years past and he hoped to be able to do so for many years to come. No one had served the Institution better than Sir Harry, and he had said "No" to a great many other calls for service so that he might devote his energy to the work they were all interested in. Mr. George Monro, in seconding, endorsed all that Mr. Sutton had said.

Mr. Monro next proposed the re-election of Mr. G. J. Ingram as secretary. It needed but few words from

him to do this, as they all knew that they had an excellent and hard-working secretary, who handled the work of the Institution in a wonderfully economical manner. Mr. W. Icton seconded, and the motion was carried unanimously.

After those of the committee who retired by rotation had been re-elected, with Mr. Bernard Crisp and Mr. A. J. Woods added to fill vacancies, and the auditors and arbitrators had been appointed, Mr. McKerchar and Mr. Harry J. White, the latter representing the Worcester Auxiliary, were elected scrutineers of the ballot.

CANDIDATES ELECTED.—The meeting then adjourned until later, when the result of the poll was declared. The following candidates were elected in the order named: Walter Crossman, John Smith, Emile Fornachon, James Hussey, John H. Witty, John E. Ellis, Mary Lockyer, Frank Reed, William Farr, Mary A. Stirling, George Murray, Catherine Spiney, Annie Howard, James Lee and John Jolliffe.

The chairman announced that Mr. Arthur W. Sutton had very kindly offered to provide £20 as a year's pension for one of the unsuccessful candidates, and this was granted to James Churchyard. Mr. George Monro also offered £10 for a year, this being allotted to Jane Langdon by request. As one annuitant had died since the voting papers were sent out, the committee, acting upon the power accorded them in the rules, elected Mary Ann Hopwood, who had been a candidate for seven years, to fill the place.

HOME-GROWN PRODUCE.

CHESTER PAXTON SOCIETY'S APPEAL.

UNDER the chairmanship of Mr. A. W. Armstrong, the twenty-seventh annual meeting of the Chester Paxton Society was held on Saturday at the Grosvenor Museum. In submitting the annual report and statement of accounts Mr. G. P. Miln, the hon. secretary, said: "It is now twenty-seven years since this society was established, and this is the first year in its history in which an exhibition of fruits and Chrysanthemums has not been held. This, as you all know, is due to the present unfortunate war, and in the interests of the society the committee thought, and rightly so, I think, that it would be unwise in the present circumstances to have held the annual exhibition last autumn. In common with many other societies and public bodies, this society is doing its full share in providing recruits for the new Armies, the sons of many of its members and also of its officials having responded generously to the appeals for young men to serve their King and country during this present national crisis. In the many object-lessons which this present war has provided us with, not the least important is the necessity for cultivating on a larger scale than hitherto products of the soil to ensure adequate food supplies for the inhabitants of the United Kingdom. Although it may not be possible to produce the whole of these in this country, it is our bounden duty to endeavour to increase these supplies beyond what has been done in the past. Towards this there are already indications that lands which have for some years been down in permanent pasture are now being broken up for the cultivation of cereals, which is certainly a step in the right direction. All movements of this kind go a long way to justify the existence of societies such as this, who have in the past done so much to encourage the extended cultivation of horticultural produce, particularly hardy fruits, in this district. Further, I believe I am right in saying that all members of this society will be prepared to do their utmost to encourage still further all movements of this kind in the future. It is yet too early to say definitely whether we will be in a position to hold the annual exhibition of fruits, Chrysanthemums, &c., next autumn, but I am sure I am voicing the feelings of every member of this society when I say that we hope that the present hostilities will have ceased long before then, and that our social and commercial life will by that time be on a fair way to resume their respective normal conditions."

Hearty votes of thanks were accorded to the officers and committee for their services during the past year, and officers and committees were elected for the present year. It was resolved that the question of holding an exhibition this year be deferred for three months.

VALE OF LEVEN AND DUMBARTON HORTICULTURAL ASSOCIATION.

THE SOURCES OF PLANT FOOD.

ON Wednesday evening, January 13, the usual monthly meeting of the above society took place in the side room of the Public Hall, Alexandria. On this occasion Mr. R. Dickson, of Messrs. Austin and McAsian, Glasgow, delivered a most interesting paper on "Some Sources of Nature's Plant Food." Councillor James Parlant presided over a good attendance. In dealing with his subject, Mr. Dickson alluded to the fact that plants obtained their chief food from the air in the form of carbonic acid. There are, however, many other substances the presence of which is necessary for the plants' growth. Ordinary soils contain them in sufficient quantities, but exhaustion takes place through time, and replacement is necessary. These chemical substances are known as manures, nitrogenous, potassium and phosphatic. These usually occur in the soil as calcium phosphates, and to dissolve them one must see that an acid is present. Nature has in a way provided the root tips to supply the necessary acid to render the phosphate suitable as a food. The nitrates occur in soils when there is decay of organic matter; they dissolve when formed. The application of nitrate must be carefully undertaken, as over-application may result in harm

to the crop. Potash is very often present in insoluble form, but to obtain it in a soluble form, rock weathering, combined with the action of carbonic acid, must be resorted to. Potash is most useful for supplying a necessary ingredient of the soil fertility, and the phosphate assists in the production of flowers and fruit. Other ingredients, such as lime, iron and probably a few more elements, all combine in keeping the soil fit and healthy for the bacteria in it. Lime, for instance, as a manure is also necessary in soil. The action of decayed organic matter sets up gases which are detrimental to plant-life. These are neutralised by the lime, which, combining with the gases, makes them harmless. Lime acts also as a destroying agent where plant-eating bacteria are present. The value of soot, leaf-mould, water, wood-ashes, farm-yard manure and other manures easily obtainable was also stated, and a great amount of information was gained in the course of what was a remarkably long and interesting paper. The chairman paid a high tribute to Mr. Dickson for his paper, and a vote of thanks to the essayist closed the meeting.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE annual general meeting of the Scottish Horticultural Association was held in the Hall, 5, St. Andrew Square, Edinburgh, on the evening of January 19. Mr. David King, the retiring president, occupied the chair, and there was a good attendance of members. The annual report, which was approved, was of a satisfactory nature. The financial statement has already appeared in our columns. The report of the membership was of a satisfactory character also, the membership standing at 1,124, composed of 927 ordinary, 188 life, and nine honorary life members. The other items of the report were also of a gratifying nature. Office-bearers for the year were appointed as follows: Hon. president, the Marquis of Linlithgow; president, Mr. W. G. Pirie, gardener to C. W. Cowan, Esq., Dalhousie Castle; vice-presidents, Mr. D. Kidd, Carberry Tower Gardens, and Mr. J. Highgate, Hopetoun Gardens; members of Council in lieu of those retiring, Mr. J. S. Chisholm, Mr. J. L. Forbes, Mr. J. Fraser, Mr. J. C. Grieve, Mr. D. T. Johnston, Mr. J. Phillips and Mr. G. Stuart. Mr. A. D. Richardson was reappointed secretary and treasurer. Captain Stirling of Keir and Mr. D. King were elected honorary life members in recognition of their past services in office. It was agreed to take steps to form a roll of honour of the members who had joined His Majesty's Army. Several other items of business were also disposed of.

Norfolk and Norwich Horticultural Society.—

At the annual meeting of this society, held at Norwich, the hon. secretary, Mr. B. Knyvet Wilson, in his report was able to announce that the balance in hand stood at £79 5s. 5d. The membership was 510, an increase in both cases on those of the previous year. After careful deliberation by the committee it has been decided—unless anything unforeseen happens—to hold the three shows of the society as usual during 1915. The spring show will be held at Norwich on April 22, the Rose and summer show at Earlham Park, Norwich, on July 1, and the Chrysanthemum and autumn show at Norwich on November 18, 19 and 20. J. A. Christie, Esq., Framingham, near Norwich, was elected president for the year. Mr. John Clayton announced that one consignment of vegetables and fruit had been despatched to the Navy.

Dunfermline Horticultural Society and the War.—

This society having promised a weekly supply of fruit and vegetables for three months to the men serving in the British Fleet, the third consignment was sent on January 20. This included Artichokes, Brussels Sprouts, Cabbages, Carrots, Greens, Leeks, Onions, Parsnips, Potatoes, Savoys, Turnips and a case of Oranges. Acknowledging former consignments, Mr. E. Jerome Dyer, London, hon. secretary of the Vegetable Products Committee, says: "I am very much obliged for your letter supplying me with particulars of your consignments. I think your supplies are extraordinarily good, and far more than we expected when you started. If I may be permitted to say so, it is an evidence of an excellent spirit on the part of the people of Dunfermline, and proves that they are prepared even to deny themselves for the good health and welfare of the men to whom we look for so much."

THE GARDEN.

No. 2255.—VOL. LXXIX.

FEBRUARY 6, 1915.

NOTES OF THE WEEK.

The Chelsea and Holland House Shows.—The Royal Horticultural Society's Chelsea Show will be held in the Royal Hospital Gardens, Chelsea Embankment, on May 18, 19 and 20; and the Holland House Show, Kensington, on July 6, 7 and 8. Plans, schedules and entry forms can be had on application to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.

Planting Roses in Early Spring.—On page 67 will be found an article dealing with some mistakes that amateurs often make when planting Roses. We think it desirable to point out that, although November and the early part of December is undoubtedly the best time of the year for planting Roses and herbaceous plants, they can also be quite successfully planted during February and March, providing always that the weather is open and the soil in fit condition for the work. Nurserymen still have plenty of good bushes and plants to dispose of, and we trust our readers will do all they can to purchase these before the planting season is over.

The Gibraltar Candytuft.—*Iberis gibraltarica* is a handsome member of the perennial Candytuft family. Evergreen in character, it flourishes in the milder parts of the country, where it may generally be employed in level planting. In colder, bleaker districts or in soils that are rich and retentive of moisture it is more satisfactory to give it a special position where soil and drainage are both under control. It shows to best advantage and proves thoroughly reliable as a perennial when planted in a dry wall fully exposed to sun. Failing such a position, then any sharp bank will meet its requirements. The soil should be liberally mixed with old mortar rubble or crushed chalk. To the latter it shows striking partiality. It flowers in the open towards the end of April and during May. The blossoms are a delicate shade of rose lilac, and are carried in large, rounded heads in such profusion as makes the leaves scarcely discernible. A native of Gibraltar, it has been grown in gardens since 1732.

Propagating *Statice latifolia* by Root Cuttings.—This is without doubt the most attractive and vigorous of the Sea Lavenders, either for the borders or the wild garden, particularly when seen in bold groups. Plants may be raised from

seed, although this method is not always to be depended upon. A better way of raising a stock of good plants is by cuttings of the roots. An old plant should be lifted now, some of the roots cut into lengths of from 2 inches to 3 inches, and put in pots of sandy soil with the apex just protruding. If possible, they should be placed in a little warmth. Small shoots will soon appear, and, as they progress, gradually harden them off. By June, with careful treatment, the plants will be ready for planting out in their permanent positions.

Insects on the Roots of Plants.—An investigation has been commenced at Wisley into the

as it is not desirable to risk infecting Wisley with these insects.

Winter-Flowering Honeysuckles.—For the sake of its deliciously fragrant white flowers at this season of the year *Lonicera Standishii*, a Chinese Honeysuckle, is well worth a place on a wall, particularly near the window. It is quite hardy and will succeed in the shrubbery, but the flowers with their unmistakable odour of Orange blossoms are not produced so freely or developed at so early a season as when against a wall. *Lonicera fragrantissima*, another Chinese Honeysuckle similar to the subject of this note, is also well worth attention. We recently saw

some good plants growing in pots and doing exceptionally well, and although the creamy white flowers were not particularly showy, they filled the atmosphere of the conservatory with their fragrance.

A Blue Flower for the Greenhouse.—One of the most attractive plants of recent introduction for the warm greenhouse is *Pycnostachys Dawei*, a member of the Labiateæ family, with dense, terminal spikes of deep blue flowers about five inches long, the plants themselves usually attaining the height of from 4 feet to 6 feet. A native of Uganda, it was first discovered by Mr. Whyte in 1898, but it was not until 1905 that seeds were sent to Kew by Mr. M. T. Dawe. It is closely allied to the Coleuses, but the genus *Pycnostachys* can be distinguished by its needle-like calyx teeth and denser spikes. It is now flowering in the Cambridge Botanic Garden, and makes a pleasing contrast with the yellow flowers

A COLONY OF THE GIBRALTAR CANDYTUFT, *IBERIS GIBALTARICA*, IN THE ROCK GARDEN.

mealy bug and woolly aphis, which infest the roots of so many plants in greenhouses and rockeries. There are several insects concerned, and the first thing to determine is how far each of these pests attacks plants in general or to what extent each is limited in its food plants. The ultimate outcome hoped for is a simple, practical remedy. The investigator would be very grateful for infected plants or for specimens or infected roots of plants, with the names attached. The enquiry would be still more assisted if those having infected plants would permit the investigator to inspect them. Specimens and enquiries may be sent to Professor Lefroy, Imperial College of Science, South Kensington,

of the beautiful but seldom-grown *Lindenbergia grandiflora*.

Useful and Injurious Earthworms.—On another page, under the heading of "Societies," we publish a report of a lecture on earthworms given by the Rev. Hilderic Friend to the members of the Birmingham Gardeners' Association. This gentleman has already discovered that, while some kinds are beneficial in the garden, others are of an injurious character. We understand that he is still investigating the matter, and would be glad to receive samples of worms from anyone who would be good enough to send them. His address is The University, Edmund Street, Birmingham.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Mossy Saxifrages Turning Brown.—It may interest "Grey Court," who you replied to on page 36, issue January 16, to know that this may be caused by damage during frost. I have a broad border of Mossy Saxifrages, and last year, when they were frozen white, some small person, no doubt fascinated by the crunching noise, walked down the middle of the border. The result was a row of small brown footmarks, which lasted all the summer, but filled up in the autumn.—WALTER DE H. BIRCH, *Walton-le-Dale, Lancashire.*

Outdoor Flowers in Midwinter.—With reference to the note on the above subject in your issue of January 23, I should be glad if you would

mentioned in your note are Cyclamen Coum and Lonicera fragrantissima. There is really no need for a greenhouse in order to obtain winter flowers. After all, the Christmas Rose is more beautiful than anything you will find in the average conservatory at the same season.—ERNEST BRYSON, *Gloucestershire.*

Onions in the West of Scotland.—The accompanying illustration of a bed of Onions in a West Scotland garden may be of interest now that the time for sowing seeds for exhibition bulbs is here. The varieties are Cranston's Excelsior and Ailsa Craig, and the average weight of the Onions is three-quarters of a pound. The size of the bed is 15 yards by 10 yards, and 2,000 Onions were taken from it. The soil is good loam, treated with cow-manure and Thompson's Vine Manure.—D. M. G.

Green Fly and Mildew on Roses.—I have noticed in THE GARDEN that so many Rose-

Roses are all fully in leaf, the top of the ground is turned over so as to cover the lime. Before we treated the Roses in this way they used to be white with mildew, and some Roses, which grow where we cannot treat them in this way, still suffer from it.—THACKERAY TURNER.

Shows, Schedules, and Judges.—It was with considerable interest that I read in your issue of January 16 the letter from "Exhibitor" *re* flower shows, schedules, judges, and considerations shown to exhibitors by the various flower show committees, and I quite agree with him and believe it possible to effect an improvement all round. In making up a schedule, a committee could not do better than follow the suggestions given in the Royal Horticultural Society's "Code of Rules for Judging, Schedule-makers, Judges and Exhibitors," and if all societies informed their members and judges that these rules would be strictly enforced, many crooked paths would be smoothed over and unnecessary worry and ill-feeling avoided. As to what are hardy flowers and what are not, it depends more on the district than on anything else, as what will do well in Wigtownshire would be useless in Inverness-shire. If it was the rule that all collections of flowers were to be judged by points, it would do away with (to a certain extent) one or two probably greenhouse-grown bunches carrying the premier honours where the other lots were better all over. By point judging in flowers, allow a maximum of 10 points to each bunch, divided thus: For quality, 3; freshness, 2; rarity or difficulty of cultivation, 3; elegance of arrangement, 2; total possible, 10. Then over the whole stand allow a maximum of 5 points for general arrangement, blending of colours, naming, &c.

The size of bunch in all cases to be stipulated or table space allowed. The staging in all cases to be erected by the committee. A points card to be given to each judge, who would be responsible for the number of points against each bunch. The cards to be put in a conspicuous place for the benefit of competitors and the public alike. This would to a great extent do away with the inefficient judge, as no one would have the audacity to come forward to act as such who had not a good knowledge of what he had undertaken. Committees generally are to blame for inefficient judges by appointing men who hold high positions in the horticultural world but who have really done nothing as exhibitors, and I maintain that unless a man has been, and is, a competitor he is not qualified to judge. In regard to assistance lent to exhibitors by the committees, I recommend the principal flower show committees to take a copy from the Carnegie Dunfermline Trust. What exhibitor who has once been to that society's Rose show but who brims over at the good treatment he received at the hands of the officials. By a note to the secretary a conveyance meets your train. On arrival at the park willing hands find you water, vases, watering pans, &c. The secretary will find you comfortable hotel accommodation at very reasonable terms. The prize money is paid over practically as soon as the judging is finished, while at the close of the show all boxes, stands, &c., are carefully packed up and put on rail without any trouble to the competitor. Possibly this could not be done at large gatherings where the trade firms put up large exhibits; but were the directors in charge as anxious to assist as those in the town of Carnegie, no doubt things could be made much more convenient.—SCOT EXHIBITOR.

A GOOD BED OF ONIONS IN A SCOTCH GARDEN. THE VARIETIES ARE CRANSTON'S EXCELSIOR AND AILSA CRAIG.

call attention to one of the most valuable winter-flowering shrubs ever introduced; I mean *Prunus miqueliana*. I bought a small plant some years ago, and it is now a bush of considerable size, every shoot, from before Christmas onwards, being covered with its beautiful white flowers, which adorn the garden and, if cut, last a long time in water, forming the most charming and distinctive house decoration imaginable. This plant is an old introduction, but when shown at a Royal Horticultural Society's exhibition two years ago was given an award of merit. It ought to have had a dozen, but since getting its diploma my specimen has shown distinctly increased vigour, and is plainly trying to live up to its position; and its price has jumped to 7s. 6d. in the only catalogue in which I see it listed. I paid 4d. Why does not somebody undertake its propagation and get it widely known? It requires no growing; it grows. Two other gems of the winter not

growers seem to suffer from green fly and mildew. I used to suffer, but do not now. I think I ought to give your readers the reasons why I now escape these plagues. I will not take up your space by telling how I came to find the cures, but just state them. It ought, perhaps, first to be said that our soil here is sandy, with very little lime in it. As soon as green fly begins, I have all the Roses well hoed round, and then a garden water-barrow is filled with water; about half a gallon of guano is put in and well mixed, and the Rose roots watered with it. I have never known more than three waterings needed, and often one is enough to clear the bushes. For mildew, just before the Roses show signs of coming into leaf I have good Dorking lump lime slaked, and when it is in the form of flour it is thrown from a shovel thickly over the ground below the bushes until the ground looks as if there had been a fall of snow. When the

The Double-Flowered Camomile.—I shall be very pleased to send your correspondent, to whom you replied on page 47, issue January 23, seedlings of the double-flowered Camomile in the spring if she will only remind me, as it is quite a weed here.—T. L. HARRISON, *Baas Hill, Broxbourne, Herts.*

The Mountain Clematis.—All that "H." says regarding Clematis montana, page 43, issue January 23, is thoroughly deserved by this most beautiful climber. There are, however, two points which might be usefully mentioned. One of these is the great superiority of C. montana grandiflora; the other is the desirability of securing these plants on their own roots. C. m. grandiflora was first brought under my notice by the late Mr. F. W. Burbidge, who had a simple pergola clad with it in the Trinity College Gardens, Dublin. It is greatly superior to the typical C. montana, and is easily struck by cuttings or layers. This brings me to the other point—that of having the plants on their own roots. This warning has been especially necessary with the red variety, C. m. rubens, which has apparently been grafted on other Clematises, and has, in consequence, died off in a number of gardens. This is a great disappointment, as it is a charming variety of a plant of the highest beauty.—S. A.

Narcissus Treasure Trove.—The unearthing of some pots of the above from a bed of fibre recently, where they had been plunged, brought back to memory the beautiful form in which this little white trumpet Daffodil was shown by my friend Mr. Christopher Bourne at the Birmingham Show last April. Among all the good things in his fifty it was, perhaps, nearly the best. Some years ago the late Rev. G. P. Haydon brought a bunch of flowers for my inspection at the Tunbridge Wells Daffodil Show; for some reason, peculiar to his eccentric method of naming his flowers, he had christened it Castaway. I promptly did a deal with him for the stock, potted a few of the bulbs and planted the rest outside. When it began to flower the following spring I was so charmed with it that I thought it worthy of a better name, and Treasure Trove, the suggestion of my wife, was one that seemed to fit it exactly. A little smaller than Mme. de Graaff and flowering a good deal earlier, it is of far more perfect form than that variety when well grown.—F. HERBERT CHAPMAN.

Winter-Flowering Heaths.—The excellent article on these valuable plants on page 40 of THE GARDEN prompts me to ask the general experience with regard to the flowering of Erica mediterranea hybrida or E. hybrida. With me it is exceedingly irregular in its dates of coming properly into flower. I have flowered it here for nine winters, and for several years previously in my former garden, which was quite near the sea. In both gardens it proved very uncertain in its coming fully into flower. I have often had it as early as November, but sometimes it could not be said to be fully in flower until well-nigh the end of January, although a few sprays might be in perfect bloom. E. carnea is more regular with me, and among that charming set of varieties sent out by Messrs. James Backhouse and Son one called E. carnea præcox rubra has been the first of the carnea varieties to flower ever since I obtained it in the autumn of 1913. These winter-flowering Heaths are of extreme, though quiet, beauty, and with the earliest bulbs give a charm to the garden in their time.—S. ARNOTT, *Sunnymead, Dumfries.*

HOME-GROWN VEGETABLES AND OUR FOOD SUPPLY.

CO-OPERATION NEEDED.

WITH the price of all kinds of foodstuffs creeping up, the present seems an opportune time to draw the attention of our readers to the desirability of cultivating as many vegetables as possible during the coming spring, summer and autumn. We do this in no sense of alarm, but purely as a common-sense precaution, so that, should the necessity arise, ample supplies to meet all demands will be available. It is quite certain that the next few months will bring to our hospitals and Red Cross establishments large numbers of wounded and sick soldiers, and supplies of fresh, wholesome vegetables will undoubtedly be very welcome to those who have undertaken the kindly duties of caring for the men who have been broken in war.

Horticultural Societies Should Help.—In our last issue we published particulars of what is already being done by the Dunfermline and the Chester Paxton Horticultural Societies respectively. The first named has already undertaken to supply the British Fleet with consignments of fresh vegetables and fruit for three months, and the latter has wisely advised its members to grow as many as may be reasonably possible. Nearly every day we receive notices that local horticultural societies are abandoning their shows this year; but the committees, usually composed of professional gardeners and keen amateurs, have not been dissolved, and the societies are still in existence. We therefore suggest that, as an outlet for their natural energies, these societies should seriously take the question of vegetable supplies in hand so long as the war lasts.

How Assistance Can be Rendered.—A local committee might, first of all, point out to the inhabitants of their district the desirability of growing good vegetables, and state plainly that capable members would be willing to give practical advice to all who needed it. In many gardens there are plenty of spaces now occupied by dilapidated sheds, or lumber of various kinds, that could be cleared, dug and manured, and soon brought into suitable condition for at least Potatoes. This, willing members of the committee could point out. Also, to bring an element of contest into the efforts of the townsfolk, it might be possible to grant certificates, the cost of which would be very trifling, to the garden or plot that showed the greatest productiveness of the most useful vegetables. Hints on sowing and planting, with the best varieties to choose for the district, could be circulated, or, if time permitted, given personally.

The Supply of Seeds.—Even better than giving such hints on varieties would be the supplying of seeds of suitable sorts by the committee. The position of the average small grower in obtaining good seeds of really first-class vegetables is often a difficult one. He, naturally, hesitates to purchase expensive packets which contain far more than he requires. But a local committee could easily arrange with a seed firm of repute for a supply of suitable kinds in bulk, and these could be sold to inhabitants in small quantities as required. We know perfectly well that any good seed firm would much rather execute a substantial order of this kind than a multitude of small ones, and the trade generally, as well as amateurs,

would be benefited by some action of this kind. Take the case of Potatoes, the most important of all our vegetables. It is now well known that an annual change of sets, and preferably those from a considerable distance, is far better than planting those that have been grown locally year after year; yet the cottager or small amateur, who only requires his modest peck or two, does not care to go to the trouble entailed in securing this change.

The Collection of Surplus Vegetables.—It is, however, in the collecting and despatching of surplus vegetables to hospitals and other establishments that local horticultural committees could probably do the most useful work of all. In most gardens, at one time or another, there are wholesome vegetables to spare; but the owner, who has, say, half a dozen Cabbages, a bunch or two of Onions or a peck of Potatoes over and above his immediate requirements would scarcely think it worth while to pack and send them to where they are most required. But let the local committees inform the inhabitants of their districts that vegetables of this kind would be received once a week at some depôt, and be suitably packed and despatched to some establishment where they are needed, and we feel sure that there would be plenty received to meet demands.

The foregoing are points that seem to us worthy of consideration in every district where a local horticultural society is in existence. Probably all would not be practicable everywhere, but the ideas could, we feel sure, be moderated or revised to suit local conditions. The question of our food supply is a national one, and it is the duty of every able-bodied person to do all that is possible to render the soil fertile and productive at a time like the present. Next week we hope to publish an article giving some simple hints on how to make the most of vegetable plots. By a preconceived plan of intercropping we know that far more might be obtained from a given area than is usually the case. In the meantime we invite the opinions of our readers on the subject, but we hope letters will be as concise as possible.

SOME HARDY LILIES.—VI.

BY SIR HERBERT MAXWELL, BART.

SUB-GENUS MARTAGON.

(Continued from page 52.)

Lilium pyrenaicum, the Yellow Turk's-cap, is a generous plant, patient of neglect and, in my opinion, worthy of more esteem than it is the fashion to bestow upon it. People take offence at the odour of its blossoms; but as the plant does not diffuse it to any distance, they need not put their noses to it. If they do, they will receive a dab of brilliant orange scarlet pollen from the anthers that hang so prettily out of the bright yellow Turk's-caps. Some friendly hand planted a quantity of the great bulbs of this species nearly one hundred years ago in the grass at Monreith; and there they remain, rising year after year to their modest splendour in June, a sure sign that summer is nearing its height. This is perhaps the best way to employ it, for I do not see any difference between those that are thus grown in the wild and some upon which, for auld lang syne, I have bestowed a choice place in a border of rather heavy loam. The scarlet-flowered variety of this Lily is a very gay affair, equally good-natured as the type. A group of the two colours mixed is very pleasing.

L. pomponium is a scarlet Turk's-cap, with flowers like scarlet sealing-wax, as bright as those of *L. chalcedonicum*; but it is a much more graceful plant. The stem is clothed with crowded linear leaves with white edges, each with a spiral twist following, says Dr. Wallace, the course of the sun. It grows, or ought to grow, 3 feet high; but it does not always receive the right treatment in our gardens, for it dislikes an open peaty soil, and only comes to its best and proves permanent when planted 4 inches or 5 inches deep in rather strong loam impregnated with lime. It flowers in June, fully a month earlier than *L. chalcedonicum*, and the most modest collection of Lilies ought to include this brilliant species.

L. superbum, the Swamp Lily.—The specific titles prescribed by botanists do not always predicate a sense of humour in those who devise them. For instance, it strikes one as incongruous to apply the epithet "*gigantea*" to a Squill (*Chionodoxa*) 6 inches high, to indicate its superiority in size to others of the same genus. But he who christened the Swamp Lily "*superbum*" perpetrated no exaggeration, for it is a truly superb creature, rising erect to a height sometimes of 8 feet or 9 feet, with from twenty to thirty blossoms on long arching pedicels, the recurved divisions of the perianth being bright orange spotted with claret. The Swamp Lily is the representative in the North American Eastern States of the Panther Lily in the Western States, and only asks for similar treatment in cultivation—that is, to have its rhizomatous roots laid 5 inches deep in moist peaty loam with a sprinkling of sand round the bulbs to encourage rootlets. Its flowering season is from the end of July through August.

L. tenuifolium is a dwarf Turk's-cap hailing from far Siberia, with brilliant red flowers opening in June and carried on slender stems little more than 15 inches high. It is a plant, therefore, and a choice one, for the front of the border, where the bulbs should be planted 4 inches or 5 inches deep in very sandy soil enriched with well-rotted farmyard manure and not suffered to lack water when growing. Thorough drainage is essential to their persistence through the winter; even so, they are short-lived, for their diminutive size does not enable the plant to store up enough vitality to survive the effort of flowering more than twice or thrice. It ripens seed, however, whence a fresh stock may be raised. This Lily has begotten upon the white Martagon a hybrid of charming quality and satisfactory constitution. It is dwarf, but more vigorous than *L. tenuifolium*, and bears a profusion of little Turk's-cap flowers of a rich apricot hue. It takes rank among the choicest of small Lilies, and is known as Martagon Golden Gleam.

L. testaceum (syn. *isabellinum*, *excelsum*), the Nankin Lily, is one of the loveliest of the race, carrying in July a coronet of large flowers to a height of 5 feet or so on a slender but steadfast stem closely set with narrow leaves, each of which is spirally twisted, suggestive of a delicate design in metal-work. The corolla is of a delightful shade of apricot, slightly tinged with flesh colour, and the orange anthers within the bell give the whole inflorescence a very rich character. The origin of this Lily is not known; as it has never been found in a wild state, it is believed to be a hybrid, probably between the Madonna Lily and *L. chalcedonicum*. The late Dr. Wallace reported that it was first noticed among some seedlings raised at Erfurt in 1846. If its parentage has been correctly divined, the Madonna strain

A BEAUTIFUL GROUPING OF LILIUM TESTACEUM IN THE BOTANIC GARDEN, OXFORD.

has proved dominant, for in stature and carriage it resembles that species, and the vivid vermilion of the Turk's-cap has been softened into the delicate tint shown in the flowers of the offspring. In cultivation the Nankin Lily requires similar conditions to the Madonna, save that it is less patient of drought. Unfortunately, of late years it has fallen in many gardens under the scourge of the fell fungus *Botrytis*; wherefore spray should be applied diligently on the first symptom of the mischief, for it is worth any amount of pains to preserve this beautiful flower from disfigurement.

(To be continued.)

DAFFODIL NOTES.

Leedsii Classes.—As I mentioned in my last notes, Mr. Morton has raised a most interesting point about the grouping of Leedsii varieties for show purposes. He suggests that when large-cupped and small-cupped blooms are exhibited together, judges are inclined to favour the latter, all else being equal. In his letter to me he quotes as definite instances to prove his contention: First, the names of the three winning collections in Section III. (London), where the first prize went to Katherine Spurrell, White Slave and Evangeline; the second to White Queen, Potent and Lord Kitchener; and the third to White Queen, Lowdham Beauty and Lord Kitchener. Secondly, the prize-winners in Section II. (London), where Evangeline, Diana, Lowdham Beauty, Waterwitch, White Lady and Marguerite Durand were placed first; Phyllis, Eoster, White Lady, Diana, Mrs. Langtry and Candidata second; and much the same class of flower third. Thirdly, he instances Group B at Birmingham, where the winning lot was composed of White Slave, Duchess of Westminster, Katherine Spurrell, Evangeline, Bianca and White Lady; and the second, third and fourth of precisely similar varieties. The obvious comment on Mr. Morton's examples is that he has ignored what happened in the open Leedsii classes at the above exhibitions; that he may not be aware that in Group B at Birmingham the price of bulbs is limited; and that Giant Leedsis are rather expensive.

If we take these facts into consideration along with those put forward by Mr. Morton, I do not think it can be said that small cups are generally favoured more than the "giants." I well remember the long discussion that went on in sub-committee before it was finally decided to suggest to the Royal Horticultural Society's Narcissus committee the present wording for Class IV. It was thought that it was not worth while dividing up the Leedsis, as in a year or two the smaller type would automatically disappear. The unexpected seems to have happened. The "bantams" have taken an unexpected lease of life,

and lovely flowers like Eoster and Wendy are the potential equals of Lowdham Beauty and Lord Kitchener. What is to be done?

Before I make my suggestion I would like to call my readers' attention to the advent of the exceedingly beautiful new type of bloom which has made its appearance within the last two years, and of which Crystalline and Mogador are exquisite examples (see illustration and note in the Royal Horticultural Society's 1914 "Daffodil Year Book.") These pointed perianths have come to stay, I think. They are, too, charming, especially when they surround a "duck" of a little trumpet or trumpet-shaped cup. I venture, then, on this proposal:

That in future all schedules should distinctly state that (whether the number of blooms required be three, six, nine or twelve), *diversity of type* is absolutely essential, and that the judges will be instructed to be very particular about this stipulation in awarding of the prizes. This could very easily be done in all schedules for 1916 if it finds general favour. Perhaps those interested will communicate with me, so that I can allude to it again in future notes.

Judging at Birmingham.—I rather rubbed my eyes when I read in *THE GARDEN* for January 9 Mr. Grindrod's suggestion that we allow prizes to be awarded to collections which do not comply with the schedule. Now, if there is one thing that I am always down on, it is this. As the Chairman of Committee, I have a good deal to say in all that goes on; so let me assure Mr. Grindrod that we are not slackers, but that those in authority try to see that all is done according to Cocker. As far as we are able, we see that there are no slips; but so great is the usual competition that it is impossible to go round all the classes and microscopically inspect each individual exhibit on the first day of the show. The onus of finding any wrong is, according to our Regulation 12, thrown on the competitors themselves, and if none of them complains, it is taken for granted that all is in order. Perhaps we should appoint an official inspector to go round and see that each flower is in its right place, and not leave it to competitors to complain. Anyhow, I will see what can be done. Let me assure Mr. Grindrod that the "S. T. H. W." in Class 22 was not the "S. T. H. W." in Class 25. The letters are the private mark of the exhibitor, who might mark every seedling he has got "A. B. C." or "S. T. H. W." and exhibit them as such; but this does not make a triandrus hybrid into a Tazetta hybrid.

I have not had much difficulty in finding the other seven or eight instances alluded to, and I see I am one of those in fault, as I exhibited a Lady Jellicoe as a 2B, when it is listed as 3B. It is possible there are two Lady Jellicoes, as mine is *very* like Lena Parker, which is down as a 2B. The President that I staged is one of Wheadon's introductions, and quite different from The President of Haydon. In the case of Sophy Primrose, I must have omitted to look up my classified list. It is one of the rather doubtful ones, but that is all the more reason why I should have done so. As no protest was made, I was not aware of my slip until I looked matters up for these notes. "Hurry and bustle I hate," says a comic song. So do I on a show morning, but they are inevitable in my case, as they doubtless are in my friend Mr. Bourne's, who was an even greater offender than myself at last year's show.

Both Mr. Watts and Mr. Chapman also staged flowers in wrong classes. I had no idea of these slips until I read Mr. Grindrod's note and began to go over the lists in the report, and I cordially thank him for calling attention to the matter. These things should *not* happen at the leading Daffodil show, and I will see that they are carefully

considered at our next committee meeting. No one is keener than I am for rigid adherence to schedule regulations, and now that our delinquencies have been pointed out, some method must be devised to reduce the possibility of their recurrence to a minimum. As Colonial eyes scrutinise our proceedings very carefully, it would be a thousand pities were an impression to gain ground in New Zealand and elsewhere that the Midland Daffodil Society allows great latitude in its members' interpretation of its schedule. It is clear that our trusting to the protests of exhibitors has been tried and found wanting. It seems to point to the institution of a show inspector.

The War and Shows.—I am busy getting together a list of the Daffodil shows and their dates for 1915. Some are already abandoned, but the majority of societies at the present time propose to hold theirs as usual. As soon as I can issue a complete statement I will do so. I would be very much obliged, if these words meet the eye

full-grown larvæ. The problem is a twofold one. How long must a merodon (inside a bulb) be immersed to make sure of killing it? And how long will a bulb stand immersion without detriment? Will Mr. Adams kindly relate his experience?

JOSEPH JACOB.

A BEAUTIFUL ROCK GARDEN FLOWER.

WHEN covered with flowers, the Androsaces are among the choicest of plants for the rock garden. Some of the more spreading kinds form broad tufts of foliage, some deep green in colour, like *A. Laggeri*, while others have silvery foliage, like the subject of this note. *Androsace sarmentosa* is a native of the

ANDROSACE SARMENTOSA, A BEAUTIFUL ROCK GARDEN PLANT WITH ROSETTES OF SILK-LIKE FOLIAGE.

of the secretary or any other member of a Daffodil society which was not included in the Royal Horticultural Society's 1914 "Daffodil Year Book," if he would communicate with me. I want that book to be as complete as possible.

Drowning Out the Merodon.—Mr. C. L. Adams, whose note appears on page 38, January 23 issue, apparently knows the trick of how to drown out the merodon. I wish he would tell us how it is done. Mr. George Stocks ("Daffodil Year Book," 1914, pages 56-57) put five bulbs suspected of containing merodons in water for forty-eight hours. Two were not infested with the grub—a grub came out of one of the other three and was found alive at the bottom of the water. It died in two days. From the other two the grubs were extracted and were soon able to eat their way into fresh bulbs.

Again, Mr. Charles E. Shea (article in Cartwright and Goodwin's 1914 List) states that total immersion for three days is not sufficient to destroy

Himalayas, from Sikkim to Kashmir, at elevations of 11,000 feet to 12,000 feet. It is a somewhat variable plant, a few of the forms approaching *A. lanuginosa* in character, but it is rather less silky. The leaves are also broader and borne in larger rosettes, which send out stolons that root as they spread, soon forming broad carpets studded with umbels of rose-coloured flowers in May. The flowers are deeper in colour towards the centre, which is pale yellow. Even when not in flower the silky rosettes are very attractive. Given a rocky ledge in full sunshine, planted in light sandy loam and peat, it soon makes itself at home. As these woolly-leaved plants from the higher elevations suffer a good deal from damp in winter, it is advisable to cover the whole plant with a piece of glass raised a few inches above it and in a slanting direction to throw off the rain. According to the "Flora of British India," four varieties are found in the Himalayas,

of which the largest form, *A. foliosa*, is now recognised as a distinct species. The last mentioned is a taller plant with larger, less silky leaves, and umbels of pink flowers borne on stems about nine inches high. *A. sarmentosa* and its varieties are easily increased by seeds, and the numerous offsets. W. I.

SEED-SOWING UNDER GLASS.

WITH the advent of the month of February, seeds of many subjects intended to flower in the greenhouse later on are sown.

Prominent among them are Begonias, Gloxinias, Streptocarpuses and Gesneras, all of which require much the same treatment. As the seeds are very small, and in many instances fairly expensive, a considerable amount of care should be taken in sowing them and in bringing the tiny plantlets through their earlier and more critical stages.

Too much care cannot be taken with the preparation of the compost on which the seeds are to be sown. A very suitable mixture may be made of two parts loam to three of leaf-mould or peat and a liberal sprinkling of silver sand. Leaf-mould, if good, is preferable to peat, but it must be of first-rate quality and prepared from Oak and Beech leaves. All the ingredients should be thoroughly sterilised in order to destroy any insects or vegetable matter. Unless this is done, a tiny moss is apt to crop up and choke many of the seedlings. This compost should be rubbed through a sieve with a quarter-inch mesh, laying the rougher portions on one side. Whether pots or pans are used in which to sow the seed, they must be quite clean and effectually drained by means of broken crocks in the bottom. Then over these may be placed a layer of the rough portion of the compost, and the pot or pan then filled to within half an inch of the rim with that which has passed through the quarter-inch mesh. A finishing layer, on which the seeds are to be sown, should consist of the same compost sifted through a sieve with an eighth of an inch mesh. The whole must be pressed down moderately firm and made quite level. The soil should be thoroughly watered before the seeds are sown, a better plan than using a fine rose being to stand the pot or pan nearly up to the rim in a vessel of tepid water. In this way the liquid will enter by the hole in the bottom, and gradually soak the soil without disturbing the surface.

While the soil is still wet the seeds should be sprinkled thinly thereon. Minute seeds will require no covering, except it be a pane of glass or a sheet of paper laid over the pot or pan. In a structure

with a minimum temperature of 65°, rising during the day, the seeds will soon germinate. Directly this takes place the glass or paper should be removed, but especial care must be taken to shade from the sun's rays, as while so delicate a few minutes' exposure to bright sunshine will permanently injure the young plants. Whenever the seed pots want water, it should be given as before directed.

When the young plants are large enough they must be pricked off. This is an operation that requires considerable care. The pots should be prepared the same as detailed for the sowing of the seeds, and a fine-pointed stick used as a dibbler. As the young plants develop they may

ORNAMENTAL-LEAVED VINES GROWING ON POLES AND CHAINS IN THE GARDENS AT ALDENHAM HOUSE, ELSTREE, HERTS.

be potted singly, and shifted into larger pots when they require more room.

Other subjects that may be grown in the same temperature as the preceding, but whose seeds, being larger, do not require such careful manipulation, are: *Acacia lophantha*, a subtropical plant remarkable for its much-divided leaves—seeds should be soaked in warm water for twenty-four hours before sowing; *Artemisia judaica*, with gracefully cut silvery foliage, valuable for summer bedding; *Cannas*, well-known foliage and flowering plants, whose seeds, like those of the *Acacia*, should be soaked in warm water for twenty-four hours prior to sowing; *Eucalyptus globulus*, the well-known Blue Gum, so much used in the flower garden in the summer; *Grevillea robusta*, remarkable for its finely cut Fern-like

foliage; *Impatiens Holstii*, one of the best of the Balsams for the embellishment of the outdoor flower garden, with bright vermilion-coloured blossoms; *Lantanas*, pretty, free-flowering plants, which can be readily raised from seeds; and *Ricinus* (Castor Oil Plant), which presents such a bold feature in the flower garden during the summer.

A somewhat lower temperature, say, that of an ordinary greenhouse, is during February and March available for the raising of a vast number of seeds, including such well-known subjects as *Antirrhinums*, now so much used; *Asters* of different sorts; *Brachycome iberidifolia* (Swan River Daisy); *Campanula pyramidalis*, a well-known and popular biennial; *Giant Hemp*, a grand plant for the subtropical garden; *Clarkias*, to form a succession to the autumn-sown plants; *Dahlias*, if it is desired to raise these from seeds; *Helichrysums*, a very pretty race of *Everlasting Flowers*; *Lobelia speciosa*, whose blue flowers are always much appreciated; *African* and *French Marigolds*, showy and easily grown flowers; *Mignonette*, whose flowers are much appreciated in the greenhouse before they expand out of doors; *Nemesias*, charming annuals for pot culture and also for flowering out of doors; *Petunias*, well-known and showy flowers; *Phlox Drummondii*, which as pot plants in the greenhouse are very showy; *Rhodanthe Manglesii*, a pretty *Everlasting Flower*; *Schizanthuses*, to succeed those sown in the autumn; *Stocks*, whose delicious fragrance is admired by all; *Zea Mays variegata* (variegated Indian Corn), very showy in the summer; and *Zinnias*, a free-growing race of plants whose bright-coloured blossoms are remarkably showy. H. P.

ORNAMENTAL-LEAVED VINES.

IN my opinion the value of these for effective purposes in our pleasure grounds is much underestimated, and when their true value is better understood I predict for them a great future. Since the introduction from China of so many beautiful and distinct varieties, these create a wealth of lovely tropical foliage absolutely different from anything else, and during the autumn the majority present such a beautiful effect that their beauty must be seen to enable one to fully realise their worth.

There are many ways in which these can be used, either for clothing pergolas, walls or buildings, trained up on tripods, or used as shown in the accompanying illustration. From my point of view they are never seen to better advantage than when grown in this way, and being such rapid growers, it takes but a short time to furnish the poles and chains. Large poles are probably the best, as when these are charred and have received a good coat of tar they will last in

good condition for many years. Either two or three lines of stout chain should be used, with holes bored through the uprights, through which the chain should be threaded and looped in a graceful manner. The posts must be placed at regular intervals to suit one's taste, but not too closely together, or the effect will be marred.

The ground should be drained and made fairly rich, as the stronger and better the growth the finer will be the foliage, naturally. This being once accomplished, the labour incurred will be very trifling. Beyond training and tying the growths, during spells of dry weather copious supplies of liquid manure should be given, and the surface dressed with a good coating of half-rotted cow-manure. Thoroughly syringe the foliage in the late afternoon after a hot day. A reasonable amount of pruning should be carried out during the winter and the growths made thoroughly secure.

Large, stout Larch poles should be used for tripods, preparing them in the same way as previously advised, the three being securely fastened together at the top with stout wire. One plant should be placed to each pole, and when it becomes thoroughly established it will be very conspicuous standing out in the shrubberies.

For pergolas there is nothing more valuable than these Vines for quickly clothing them and for effect, whether viewed from a distance or when walking beneath them. For clothing spaces on large walls or buildings these are also invaluable, notwithstanding that more labour is necessary in relation to training them than in the other ways mentioned.

Varieties.—Here we cultivate a large number which probably include the best of them, but I will mention only those which I consider to be among the most worthy and distinct: *Vitis Coignetia*, *V. megalophylla*, *V. Thunbergii*, *V. vinifera purpurea* and *V. Brandt*, all large-leaved varieties; *V. heterophylla delavayana*, *V. armata* and *V. Prasezkii*, medium size; the smaller-leaved *V. flexuosa Wilsonii*; *V. Thompsonii* and *V. himalayana rubrifolia* (the latter a very striking new variety).

Elstree.

E. BECKETT.

MISTAKES TO AVOID WHEN PLANTING ROSES.

IN the planting of Rose trees, as in most other things, there is a right and a wrong way, and although the operation is apparently simple, it is quite possible for the novice to make many mistakes. It is important that this work should be carefully done, for much of the future success or failure of the plants depends upon it. I have therefore endeavoured to describe some of the mistakes most frequently made, in order that readers may avoid repeating them.

Many failures are accounted for by the fact that the roots of the bushes do not receive sufficient

attention prior to planting. Long roots should be shortened, and all bruised and broken parts entirely removed. If allowed to remain, the damaged portions will decay and the rot will spread to the hitherto healthy roots. It is necessary to use a sharp knife when pruning the roots, so that a clean end may be left.

It is also a mistake to allow the roots to come into contact with any crude manure. If manure is used at all, it should be well rotted and thoroughly mixed with the soil. Many novices, hearing on all sides that Roses are gross feeders, imagine that the new bushes will do all the better if a nice little dose of manure is placed about the roots. In truth, quite the reverse is generally the case, the strong manure causing the dormant roots to rot rather than encouraging the formation of new ones. The better practice is to use a small

surprised to find how loose the soil has become round the plants in such a short space of time. Large plants that offer resistance to the wind will soon become loose again, however firmly they are planted, unless they are secured to a stake. The alternative is to shorten the longer growths considerably, which practice will not in the least diminish the chances of future success.

Finally, the use of a mulch of long manure is often advised; but, personally, I think this practice is a mistake. In my experience, the only effect of such a mulch applied during the winter is to keep the surface of the soil cold and damp, in many cases making it positively sour. Such conditions cannot possibly improve the health of the Rose trees. It is far better to keep a good loose surface, through which the life-giving properties of sun and air may penetrate to the newly

AN EFFECTIVE GROUPING OF THE MOONLIGHT BROOM, *CYTISUS SCOPARIUS SULPHUREUS*.

quantity of soft fibrous loam, which should be shaken well in among the roots. This will do much to encourage speedy root action. Artificial manures should also be avoided when dealing with new bushes. Bone-flour may be used with safety, a handful being sprinkled around each plant just beneath the surface.

Another very frequent mistake committed is planting too deeply. I have often seen fine plants utterly ruined by being placed several inches too deeply in the soil. The bush should be so placed that the point of union between the stock and the scion comes as near the ground-level as possible. Then, again, the bushes are often planted much too loosely. Roses require to be planted firmly—the firmer the better, excepting when the soil is wet and sticky. In that case it is better to allow the soil to become more friable before finally treading up. In all cases it is advisable to go over all newly planted Roses a week or two after planting, and tread them up again. Growers will be

forming roots. Should a spell of very severe weather set in, protection may be provided for the more tender varieties by drawing the surrounding soil up to their bases. Some advise using ashes for this purpose, but only ashes that have been exposed to the air for some considerable time should be used.

W. A. E.

THE MOONLIGHT BROOM.

AMONG the hardy Brooms, as the *Cytisuses* are generally called, few are more beautiful than the variety of the common kind named *Cytisus scoparius sulphureus*. Except that it is dwarfer and rather more prostrate, in general appearance and habit this resembles the type, which may so often be seen clothing the sandy banks of railway cuttings, or forming hummocks of green and gold on the waste spots of commons or even the country roadsides. The colour of the flowers is, however, different, being, as its varietal name implies,

of pale sulphur yellow. It is an excellent hardy shrub for poor sandy soil, and is seen to the best advantage when planted in good-sized colonies, as seen in the illustration on page 67. It flowers about the end of May or early in June, but even at other seasons its slender green stems are attractive. In common with other Brooms it should be planted when quite small, as old plants resent disturbance. G. B. D.

SHRUBS WITH FRAGRANT LEAVES.

SHRUBS that have fragrant leaves and are hardy in most parts of the country are comparatively rare; but if those kinds are included which are hardy in Cornwall and other places with a similar climate, a fair number may be enumerated. Fragrance is the only attribute of some of these shrubs, for the leaves possess little beauty and the flowers are not showy. In a few instances, however, the combination of fragrant and evergreen foliage exists, while in others the flowers are worth taking into consideration. Some of the more ornamental shrubs may be grown by themselves, others are better represented by groups, while some are seen at their best when planted as informal hedges. One of the first families to attract attention is *Artemisia*. Most of the shrubby kinds have fragrant leaves, and some, however, are weedy. Two of the best are *A. tridentata*, a native of the Western United States, which has silvery foliage, and *A. Abrotanum*, the common Old Man or Lad's Love. Both are shrubs to grow in our gardens, and the last mentioned is, of course, well known everywhere, but the former is rarely seen. They are useful for groups or informal hedges. The Cotton Lavender, *Santolina Chamæcyparissus*, is a yellow-flowered, silver-leaved, dwarf-growing plant of value for its coloured foliage, which is strongly scented when rubbed. A green-leaved *Santolina* may be had in *S. rosmarinifolia*. Both are natives of Southern Europe, and are excellent for massing in poor ground. *Laurus nobilis* (the common Bay) is an evergreen shrub which may be grown in all except the coldest parts of the country. Though in many places it is met with in the form of a good-sized bush, it attains much larger proportions in the mild climate of the South-West Counties; and in the vicinity of Port Talbot in South Wales specimens upwards of 40 feet high are to be found. Its fragrant leaves are often used for flavouring. The Lavender makes an excellent low hedge bordering a path. Its silvery leaves are less fragrant than its flowers, but they are sufficiently charged with oil to give

off a decided scent. The Rosemary must not be forgotten; it ought to be in every garden. *Lippia citriodora*, popularly called the Scented Verbena, is only suitable for the warmer parts of the country. In the island of Rothesay, however, it develops into a large bush in the open ground. Its leaves are very fragrant, the scent reminding one of lemon. D.

THE CULTIVATION OF TROPÆOLUM SPECIOSUM.

A LITTLE more than three years ago I was informed by a Cornish lady visiting me of the great beauty of the *Tropæolum* creeper, and I was desirous of seeing it established in my own

THE FLAME FLOWER (*TROPÆOLUM SPECIOSUM*) SCRAMBLING OVER A ROUGH SUPPORT.

garden. On making my wish known to my friend I received very little encouragement, for she maintained that it would only grow in Cornwall and in the Highlands. But I determined to try to grow it. I did not know which *Tropæolum* my friend referred to, nor did she know the name; but I guessed it would be either *T. speciosum* or *T. tuberosum*.

I bought a root of each—about March was the time, I think—and awaited developments. *T. tuberosum* came up and made great growth,

but never flowered, nor has it since flowered with me, though I have carefully wintered the tubers each year. *T. speciosum* never came up, and some months after planting I unearthed it, and found it quite dead and almost rotted away. It was a strong root, and I attribute my failure to planting it in a vertical position instead of horizontally, and also not deep enough. The same year I bought another plant, well established in a pot, with a growth several feet long. This, notwithstanding great care, languished and died.

My confidence in being able to grow the creeper was naturally shaken; but the following winter I bought a dozen small roots (like the first, advertised in your excellent paper).

You can imagine their size, for they were wrapped in moss and carried in an ordinary business envelope. With them were instructions for planting, which were to plant them horizontally and 9 inches below the surface. These instructions, vital as they are, are not sufficient. My idea was to plant each one in a different part of the garden. I had, thus, twelve different sites, and I hoped that one at least of the twelve would be a success. Six of the plants came up, and two or three made good growth, but none flowered. This was not to be expected, for they were very small roots. This was in 1913.

In 1914 two of the plants made very conspicuous growth, and one was a mass of bloom and quite the most striking feature in the garden. Now I come to the point of this letter. The roots of both of these plants are covered. One is in the backyard and planted against the wall underneath cobble stones, which were replaced. The other one was planted in a shrubbery near a root of common London Pride. The former did the best last year, but the latter has sent a side root underneath the Saxifrage, and whereas the original root was very feeble, there were some very vigorous shoots coming out through the Saxifrage, which makes me think that this plant will do well this year. I am even hoping that the creeper will get hold of the Rhododendrons, &c. in the shrubbery. It is most

evident to me that this creeper requires protection for its roots, and if I planted any more they would be placed 12 inches deep underneath a big clump of Prince's Feather, or under the tiles of the backyard, in a sunny part. Both of my plants are in sunny places. [The best plants of *Tropæolum speciosum* that we have seen were at Westwick, Norwich, where they have a north or north-west position.—ED.]

Norton Cottage, Halton, Cheshire

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Muscat Grapes.—To force Muscat Grapes successfully, the roots ought to be confined to the inside of the house. The Vines which were started in November will now be in active growth, and if the border is well drained and not too deep, the roots will be in need of regular supplies of water. Liquid manure and some approved fertiliser must also be given at intervals. A night temperature of 65° must now be maintained, and sun-heat husbanded as much as possible by closing the house early in the afternoon. When in flower, much care is needed in keeping the temperatures equable. The bunches must be pollinated with a camel-hair brush, and if there are *Hamburgh* Vines flowering in another house, the pollen will be of great help in setting the Muscats.

Late Muscat Grapes.—The Vines must be got ready to start by the end of the month or the beginning of March. Both house and Vines must be thoroughly cleansed, and the border top-dressed with fresh materials before starting the Vines into growth.

Melons.—Lose no time in putting out the young plants on the hot-bed as soon as they are ready. Plant them on small mounds of soil, leaving room for top-dressings of loam as the roots develop. Sow more seeds for a successional crop.

Plants Under Glass.

Amaryllis.—A batch of bulbs may be got ready for flowering in April. After thoroughly soaking the soil, a portion of it may be removed to make room for a top-dressing of fresh materials. In some cases the bulbs will need repotting. Water must be carefully afforded till growth is active.

Gloxinias.—Batches of these may be started into growth as required. Place the tubers in shallow boxes filled with leaf-soil, and put them in a warm, moist house for a week or two prior to potting them into their flowering pots.

Salvia azurea grandiflora.—Cuttings of this beautiful *Salvia* will root readily in cold frames. Insert five or six cuttings in a 5-inch pot in a light, sandy compost. Keep the frame close and shade the cuttings from bright sun till they have rooted. Some of the most promising of the old plants may be shaken out and repotted.

Salvia splendens.—If cuttings are available, a batch may now be inserted in 4-inch pots and placed in the propagating-case. When rooted, pot them singly into 3-inch pots and keep them growing in a moderately warm house. They must be well syringed, or red spider will attack the foliage.

Humea elegans.—The plants which were raised from seed last year should now be ready for moving into their flowering pots. Pot firmly in a compost of fibrous loam, leaf-soil, lime rubble and coarse sand. Do not attempt to hasten growth by forcing, or failure will result.

The Flower Garden.

Montbretias.—The corms which were dug up in the autumn must now be planted in their flowering quarters, as growth is on the move. If the ground is too wet, a little dry soil from the potting-shed will facilitate the work. Plant only the best bulbs in the flower borders; the smaller ones may be put out in the reserve garden.

Cannas.—The plants which have been wintering in a frost-proof shed may now be brought out and potted. The stools must be shaken out and divided, potting only the most promising portions.

Dahlias.—If propagation by cuttings is desired, the roots must be placed in boxes and covered with soil. Stand the boxes in a warm, moist house to induce the plants to grow. Insert the cuttings singly in small pots filled with a light, sandy compost. After watering them in, plunge the pots in a hot-bed in the propagating-case, keeping the cuttings shaded from bright sun. The single varieties may be increased by seed, which may be sown now.

Climbers on Walls and Pergolas.—Growth on many climbing plants is now on the move, and

any pruning and training not yet done must be no longer delayed. The young growths of some of the Clematises must be kept tied, or they will be damaged by rough wind.

The Hardy Fruit Garden.

Raspberries.—Old plantations may now have their final thinning of the canes. Where the canes are secured to wires, they may be thinned to about six inches apart. Lightly fork the ground between the plants and apply a good dressing of well-rotted farmyard manure. Autumn-fruiting Raspberries must be cut down to the ground-level. If it is intended to make new plantations, the ground must be thoroughly prepared by trenching and manuring. Plant in rows 5 feet apart and 4 feet between the plants. Cover the rooting area with short litter. Before growth commences cut down the canes to within 8 inches of the ground.

The Kitchen Garden.

Spinach.—Where this vegetable is in great demand, small sowings may be made in cold frames. A mild hot-bed will considerably enhance the progress of the plants. Towards the end of the month a sowing may be made on a sheltered border outdoors.

Turnips.—A sowing of an early kind must be made as soon as the ground is in suitable condition, and further sowings may be made at intervals.

Brussels Sprouts.—A small sowing of this vegetable may now be made for early supplies. Sow in boxes and place them in moderate warmth till the seedlings are through the soil. When large enough, prick out the young plants on a bed in a cold frame.

Autumn-Sown Onions.—The mild winter has been favourable to the growth of these. Have a piece of ground ready on which to transplant them as soon as the weather will allow.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Fruit Under Glass.

Early Melons.—The earliest batch should now be ready for planting in their fruiting quarters. Do not be in a hurry to plant until the soil has become thoroughly warmed. It is the usual custom to grow Melons on small mounds or hillocks, but excellent results are to be obtained if, when shifting them from the 4-inch pots, they are moved into 6-inch pots which have had the bottoms knocked out and replaced by large pieces of turf. Then, when planting, simply plunge the pots to the rims in the bed as they are. This prevents the plants receiving any check in removal to their permanent quarters.

Early Vines.—Disbudding should receive attention. In houses where the Vines have been bent over and tied down to regulate the flow of sap, let the canes be secured to the wires, exercising caution that the young shoots are not broken, as they are very brittle at this stage. Do not hurry to tie down the young growths unless they are actually touching the glass, as the growths withstand handling much better when they commence showing their bunches. Continue to maintain a fairly humid atmosphere until the flowering starts. Drier conditions should prevail when this stage is reached; a slight damping of the pathways and border, however, will do no harm if the weather is very bright.

The Kitchen Garden.

Capsicums.—Where required, seed may be sown in heat. The plants are easily grown, if kept free from insect pests. Grow in a moist atmosphere, and, after the pods have formed, drier and cooler conditions will suit them.

Brussels Sprouts.—The earliest lot should now be sown thinly in boxes in a temperate house. As soon as the seed leaves have developed, give cooler conditions, so as to induce a sturdy growth. Later they may be pricked out into frames, and gradually hardened off ready for planting out by the last week of April.

Peas.—The first opportunity should now be taken to make an early sowing. If the ground remains cold and wet, take out a small trench to a depth of 6 inches and fill in with some dry soil; potting-shed refuse will generally do for this. As a prevention against the ravages of rats and mice, treat the seeds with a dressing of red lead or paraffin before sowing.

Plants Under Glass.

Dracaenas.—Plants which have become at all leggy should now be topped, before they start into active growth. A few notches should be made on the part of the stem immediately below the leaves, and moss tied round. The remainder of the stems, after the tops have rooted and been potted, may be cut into a number of eyes, if the increase of any variety is desired.

Tuberose.—Place a batch of bulbs in heat where there is plenty of moisture in the atmosphere. Watering is not necessary until signs of growth are evident. The syringe, however, should be used freely, and as the plants are so subject to green fly, the occasional use of an insecticide will be necessary.

Hydrangea hortensis.—Plants may be had in flower by the middle of May if started into growth now. Any in need of potting should be attended to, using some artificial manure in the compost. The colour of the flowers generally desired is blue, and in some localities they are blue naturally. There are preparations on the market for turning the flowers of *Hydrangeas* blue, but as they contain a large proportion of iron, it is wise to use them with extreme caution.

Saintpaulia ionantha.—This bright little plant is a most useful subject for keeping the edges of plant stoves gay, as it is almost perpetually in flower. A packet of seed usually produces a variety of hues. The best of these may be propagated from leaves, which soon take root and form plants.

The Flower Garden.

Lawns.—Take the opportunity during a dry spell to deal with Daisies. The largest patches should be removed carefully with the aid of a fork, and the remaining small ones have an application of Daisy-killer, which should not be used any more sparingly than directed by the makers, or the results will not be satisfactory. The lawn, after being treated, will assume a rather brown and burnt appearance; this will gradually disappear as the coming warmer weather encourages the thick growth of young grass resulting from the use of the lawn sand.

Climbing Roses.—Any plants not yet tied up should be dealt with, before the buds become too prominent. A judicious thinning of the growths not only results in finer flowers, but there is less danger of well-thinned growths producing premature buds, which are liable to be injured by late spring frosts.

Pansies.—When required for general summer bedding, Pansies are sown during August and September. It is, possible, however, to have a good display during autumn if seed is sown now in boxes indoors. After germination has taken place, harden off the seedlings before pricking them out in a cold frame.

The Rock Garden.—This most interesting branch of gardening has become very popular during recent years. Most gardens nowadays include a rock garden; indeed, in some establishments it has become the main feature. Where a rockery is to be formed, the situation will have much to do in deciding the form it is to take. Sometimes a rock garden can be made more attractive by the inclusion of water gardening in the scheme, keeping in view that it must have full exposure to the sun. A charming effect is obtained by the reflection of flowering plants in the water. Then, too, Water Lilies will flower long after the bulk of the alpine have passed out of bloom, and so retain interest in this garden. Where the site of a rock garden is level, the addition of a few large subjects, such as Bamboos, Japanese Maples, Pyrus and Broom, will do much to relieve the monotony; they should, however, be planted with discretion.

JOHN JEFFERY.

Castlemilk Gardens, Lockersbie, N.B.

APPLES AND PEARS: THEIR FLAVOUR AND PEDIGREE.

NOTES FROM AMERICA.

THE pertinent ideas of Mr. Chapman on the flavour and pedigree of Apples, as set forth in his comprehensive article on page 595 of *THE GARDEN* for December 12, 1914, are of peculiar interest to growers of the present day, when so much is sacrificed to appearance and productiveness. Verily it is an age of commercialism in which we live, in the garden and orchard as well as in most other branches of industrial life. But I see no reason for losing our senses in this absurd chase for pecuniary gain. If certain Apples are not worth growing because of their inferior flavour or lack of flavour, let us drop them and substitute better ones. If these are less productive, as some of them often are under ordinary treatment, then let us give them extraordinary treatment and care, as, I am happy to say, is now being done in many parts of this country to-day, with very excellent results.

We cannot produce a superior article of any kind anywhere without some extra care and intelligent labour. Why should we expect to subvert or avoid natural laws in the orchard any more successfully than we can in the shop or factory? Does it cost more to raise good fruit? Yes. And do the people want only cheap Apples, and are they content with anything that looks large, red and handsome? Perhaps so, if they do not know any better. The masses are largely untaught as to the quality of an Apple, and they buy on sight, or they order "some Apples" to be sent home. The dealer dumps them out of a barrel or basket, and off they go, tough, woody and insipid they often are, though large, smooth and red, perhaps like the Ben Davis, Baldwin and other marketable sorts of that ilk that grow easily in abundance with scant care and culture.

Are Growers to Blame?—But are the growers free from blame for this condition of affairs? If more fruit of the better quality were found in the general market, even at a slight increase in price, the people would enjoy it more, be led to enquire as to the variety, and return for a new and greater supply. These are facts which must be conceded by all intelligent growers, dealers and consumers. Hence it is that Mr. Chapman insists upon flavour as the motive to work for in the orchard. He pleads for the brain and palate. And so have I for many years. And the Editor of *THE GARDEN* seems to think our point is well taken. Mr. Chapman speaks of our American Mother Apple, which has long been regarded with much favour for its fine quality everywhere. And yet we do not find it in the market. He says its origin is uncertain, but Thomas described it sixty-seven years ago as originating in Bolton, Worcester County, Mass. Just how it was produced or why so named is, however, unknown. It is a beautiful red Apple of medium size, with tender, rich, aromatic flesh that pleases the most discriminating palate. It is therefore attractive as well as excellent. But growers find the tree a slow grower and not very productive, and they advise top-working upon more vigorous stock. Hence it is listed as desirable for the home orchard, but not recommended for general "commercial planting." Afraid to risk it, you see.

"Chance Seedlings."—That many of our best fruits come to us haphazard, no one knows how, is perhaps true, though I would not embrace all in that assertion, as there are some with distinct pedigrees, scientifically produced. And yet Nature has often beaten our most skilful hybridisers. We call them "chance seedlings," but Nature takes no chances; she works with a definite purpose and design, whether we understand it or not. For years I have been trying very hard to trace the precise origin and pedigree of our famous Esopus Spitzenburgh Apple, that *sine qua non* of Apple flavour, that prince of the realm, which is only rivalled by our Newtown Pippin that captured the palates of English Royalty long years ago. Our Government Pomologist begged me to clear up this pedigree if possible. That it first appeared here in this Esopus region, where I live, some two hundred years ago is now conceded. But just how it came into existence, and at what particular point, will never be known. That it was the product of Nature, unaided by man, seems very clear. Fruit culture at that period was wholly unknown here, and it is not strange, therefore, that no record of this important advent in the realm of Pomona is found.

The Origin of Jonathan Apple.—Then, too, look at the history of the Jonathan Apple—another charming red package of princely flavour, often regarded as a "seedling" of the Spitzenburgh, though erroneously, as I believe, in spite of its similar characteristics. Of this Apple we have very definite and authentic record as to the place of its origin, but nothing of the method of its production. The original tree stood upon a farm in Ulster County, New York, among the foothills of the Catskill Mountains, some ten miles from my home. And this tree was still living in 1845, having been in bearing some twenty-five or thirty years. But nobody ever knew how it came to produce such a superior Apple. It grew among some low shrubbery along the fence on this farm of Philip Rick, and therefore must have been a product of Nature in some mysterious way. The beautiful dark red colour of the fruit drew attention to it, of course, and saved the tree from destruction with the wild brush around it. This, together with its rich flavour, soon won a place for it in the nursery where it was afterwards propagated extensively, for a time. It bore different names at first, including that of Philip Rick, who, it would seem, was entitled to the honour perpetually. But it was finally named Jonathan, after a prominent gentleman of local celebrity who is credited with bringing the variety into public notice. It has been known as an Esopus seedling, but I have been unable to find any evidence of this aside from some similarity in type, nor is there any record of that Apple growing in the vicinity at that time. Thus we are left in a sea of conjecture and speculation concerning this most valuable "foundling."

The Seckle Pear is another product of unknown ancestry with no apparent father or mother, as Mr. Chapman aptly suggests. Must we then ascribe to Nature and natural processes, unaided by man, the credit of producing our choicest fruits? Our famous hybridising wizard of California would answer "No," most emphatically, pointing to his many wonderful creations in the garden and field, of which much might be said. And yet all he has ever done, or expects to do, is to assist Nature, which he frankly admits. In these times, when we work more intelligently upon definite lines, our records of methods will,

of course, be more complete and satisfactory. And yet this whole matter of improved varieties, from the pollen and seed, through all the various stages of elimination and selection, is a very slow and precarious process, requiring great care and patience. And the reward is often very disappointing. In addition to the necessary botanical skill, there must be a true love for the work.

It is a well-known fact that Nature never creates any duplicates, and for this reason alone the plant breeder finds his opportunity. He has therefore the widest possible range of variation, depending solely upon his skill and knowledge. In the *régime* of Nature the changes and variation of plant-life are very slow, though continuous and certain. Here it is that man may step in, hasten matters and get quicker results. He can also open up a great vista of change and variation by crossing the sexual elements of the blossoms; and thus prevent inbreeding. Nature does this by the help of insects, but this, of course, is apparently indiscriminate, and without special design or purpose. But the intelligent plant breeder seeks to combine certain qualities of excellence and value. To this Nature assents, and says, "Go ahead; I'll help you," and she does, as long as her laws are not transgressed. It has been said that fruits automatically adapt themselves to the tastes and desires of the people for whom they grow, and there is some evidence to prove this. The universal adaptations of Nature to existing conditions are indisputable. But while there are certain fixed principles in plant breeding, there is no such thing as an exact science, any more than there is in the reproduction of the human species. We can blend certain characteristics by crossing, but certain others may slip in during the process that we never dreamed of or did not want. So we can never rely upon any precise result. We can coax Dame Nature, but she will not be driven.

Kingston, New York.

H. HENDRICKS.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

Varieties for the Outdoor Border.—The Chrysanthemum survives if left out during the whole year. The old stems die, certainly, but suckers grow from the roots every winter. Sometimes severe frosts injure the young suckers, and in clayey soils in low-lying districts a few may be killed, but usually in such cases late suckers appear in the spring. Although border varieties may be grown without the aid of glass, it is an advantage to propagate cuttings in a frame during February and March. Old roots will do good service if left in the border year after year, but it is not the best way to grow Chrysanthemums, even for the furnishing of open borders. The roots should be lifted, divided and replanted, or cuttings propagated from them annually; then the best results follow. In these days only a few of the old varieties should be retained, as those of recent introduction are so much finer. They are better in habit of growth, in the quality of the blooms and in colours. The majority of the plants are dwarf, and so we are able to have a fine display of blossom on plants that do not require much staking. Furthermore, the display may be had from August to November. The following varieties will afford satisfaction to every amateur cultivator.

Varieties Flowering in August.—Lena, terra-cotta, 2 feet high; Fée Parisienne, deep mauve, long flower petals, 2½ feet; Caledonia, pure white, 2 feet; Mme. C. Perrier, creamy white, suffused pink, 2½ feet; Tapis de Neige, pure white, very free, leave undisbudded, 2 feet; Normandie, delicate pink, 2½ feet; and Mrs. A. Willis, yellow, shaded red.

September-Flowering Varieties.—Touraine, porcelain, very beautiful, with incurving petals, 2 feet; Whitepoint, reddish lilac, points of petals tipped with white, 2½ feet; Vésuve, chestnut crimson, 2 feet; Tonkin, reddish orange, 2 feet; Tapis d'Or, golden yellow, fine for narrow borders, only 1½ feet; Savoie, pure white, 2½ feet; Rosie, terra-cotta, 2 feet; Queen of the Earlies, a very large white, 3½ feet, suitable for masses at the back of a broad border; Pont de Jour, rosy white, large blooms on dwarf plants, 1½ feet; Polly, deep orange, 2 feet; Patricia, mauve pink, a lovely variety, 2 feet; Orange, orange and terra-cotta, 2½ feet; Norbert Purvis, golden salmon, 1½ feet; Nellie Hemsley, a good pink, 2 feet; Mrs. A. Thomson, a rich golden yellow, 2½ feet; Miss Birchfell, blush pink, gold centre, 2½ feet; Minnie Carpenter, terra-cotta, 2½ feet; Mme. A. Nonin, a very fine pink, 3 feet; Mabel Roberts, a deep pink, flowers freely on long, stiff stems forming beautiful sprays; Le Pactole, bronzy yellow, 3 feet; La Somme, deep mauve pink; La Rhin, reddish terra-cotta, very effective and good for cutting, 2½ feet; Jimmie, crimson purple, 2 feet; James Bateman, pure pink, large, 2 feet; Hermine, pure white, 2½ feet; Goacher's Crimson, rich crimson, 2½ feet; Gertie, salmon pink, shaded gold, flowers freely over many weeks, dwarf, 1½ feet; Eden, bright rose, a good variety for disbudding, 2½ feet; Cactus, rich terra-cotta, 2½ feet; and Champ d'Or, canary yellow, 2 feet.

October-Flowering Varieties.—Champagne, ruby red, 2½ feet; Crépuscule, purple red, 3½ feet; Diane, pure white, 3 feet; Gustav Grünerwald, light pink, 1½ feet; Btoile d'Or, yellow, 2 feet; Primevère, primrose, bushy habit, 2 feet; Pride of Keston, reddish rose, 2½ feet; Mrs. E. V. Freeman, deep crimson, 2 feet; Mme. Marie Massé, lilac mauve, 2 feet; Lorraine, crimson and purple, 3 feet; Lentz, deep pink, 2 feet; and White Quintus, 3 feet.

The cuttings may be propagated in small pots or dibbled in in a sandy compost in boxes. At this season, if they are kept in a frame rather close and very lightly syringed, also lightly shaded from bright sunshine, roots will soon form without placing squares of glass on the cuttings themselves. When rooted, the young plants must be transplanted once further apart into other boxes; then they will be ready for planting in the borders early in May.

AVON.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

GERANIUM LEAVES FOR INSPECTION (E. R.).—The Geranium leaves have been attacked by some biting insect, probably a caterpillar of the surface grub type, which hides in the soil (and is much the same colour as the soil) during the day, coming out at night to feed. Search would doubtless reveal the pest, though as its colour is so similar to its surroundings, it is by no means easy to see. Spraying with some poisonous spray, such as lead arsenate, will also check the pest, and probably spraying once in six or eight weeks would be sufficient.

HERBACEOUS BORDER (W. A.).—We should like to know a great deal more about the border. Obviously, you have one in mind; hence we cannot generalise to your satisfaction. What we would like particularly to know is the time the border has been planted, the nature or character of the soil, and how the work was done. If you give us these particulars, we can promise you a helpful answer. We are compelled to put it in this way, because the differences of soil—light and heavy—are so great that no rule of thumb principle could be laid down. The border may even want replanting, and as we know nothing of its age or subsequent treatment, any reply could only be in the nature of guesswork. As the "Answers to Correspondents" columns are intended to be of service to our readers, all we ask of the latter is to give us a clear statement of affairs in the briefest possible way, when no pains on our part will be spared to give a helpful reply.

TOP-DRESSING PRIMULAS (W. A.).—None of the Primulas named in your letter requires mulching with stone chips through the winter. Two of them, P. rosea and P. japonica, are moisture-loving, semi-bog-loving species, and given this condition in leaf-soil and loam fairly rich in humus, they reach their highest development. It is not always necessary or even desirable that the plants be submerged, or even partially so, though it is essential that moisture be within reach. With this provided, the root-fibres will do the rest. P. farinosa is a pasture plant, and is often found in Nature mingling with the dwarfest herbage, where cool conditions and often moisture are found. We give you these details to prevent your treating every rock garden plant alike, and a detail which is alien to the plant in Nature is not requisite in the garden. Nowadays because a plant happens to be of the alpine class it is surrounded by granite or other chips, and while such things may stay evaporation in the summer-time, in certain instances they are not in the least desirable plus not ornamental or even natural to a plant like P. rosea, which in Nature inhabits semi-boggy ground at an altitude of 10,000 feet or even more.

LILY POND AND BORDER (E. A.).—Unless you have definite experience as to the water-holding capabilities of the soil intended for the pond's area, you will be well advised to take greater precautions than you propose. With moisture and a fair amount of tempering, a 3-inch-thick layer at the bottom might be made secure enough, but the sides would require similar treatment and on systematic lines. We advise you to make sure of this at the start, as an aquatic pond that is not water-holding is a continual nuisance subsequently. As to the border, your plan does not show any, and your letter gives no idea of size, and without some knowledge of this and the environment of the pond any list of plants we may give you might be wholly unsuitable. Please, therefore, say whether plants suited to a water-side border are required, or whether the border is removed some distance from the pond. Please also say if the border is exposed or in a shaded position. The Water Lilies need not be planted before the middle of March, and for each plant a mound of earth, loam incorporated with manure and leaf-soil, should be prepared.

THE GREENHOUSE.

ADVICE ON ORCHIDS (E. A.).—As the whole of the members of the several genera named by you do not need the same treatment, our advice can only be taken in a general rather than an individual sense. Cattleyas, as a rule, require a winter temperature of 55° to 60°, while, as spring advances, the house will, of course, be kept warmer. In very hot weather in the summer the

temperature during the daytime may rise to 90° without any harm, providing there is a liberal amount of atmospheric moisture. Potting should be done when the new roots are about half an inch long. This is mostly in the spring, but varies according to the species. A suitable compost for Cattleyas consists of two-thirds Osmunda fibre or good fibrous peat, the remaining third being made up of chopped sphagnum moss, small nodules of charcoal and silver sand. The pots must be thoroughly well drained. When growing freely, Cattleyas need to be shaded from the sun, but when growth is completed they may only be shaded during the very hottest part of the day. When fairly ripened, less water will be needed, but at no time must they be parched up. Lælias require much the same treatment as the Cattleyas. Dendrobiums as a class need different treatment, but such as D. nobile, D. thyrsiflorum, D. wardianum and several others bloom in the spring. After flowering, they will need about the same temperature as the Cattleyas, and as soon as the young shoots spring from the base they may be repotted. Directly the roots take possession of the new soil the plants will delight in a warm and moist structure. When growth is completed, the plants must be inured to a cooler and drier atmosphere in order to ripen them, while they may be gradually exposed to full sunshine. In the winter a temperature of 55° to 60° by night, rising during the day, will be suitable. At that time they do not need much moisture at the roots, only enough, in fact, to keep them from shrivelling. Directly the flower-buds make their appearance, more water and heat should be given them. Much the same compost as recommended for Cattleyas and Lælias will suit the Dendrobiums. Odontoglossums belong to what are usually termed cool-house Orchids. During the winter a temperature of 45° to 60° will suit them, and in the height of the summer the difficulty is to keep them cool enough. They should at that time be well shaded, freely watered and plenty of atmospheric moisture maintained. This is kept up by lightly spraying the plants overhead, and by damping the stages, walls, &c. A suitable soil for Odontoglossums may be formed of two-thirds Osmunda fibre or fibrous peat and one-third of sphagnum moss (chopped), with a sprinkling of clean silver sand. Odontoglossums resent being disturbed at the roots in the summer, hence repotting should be done in the spring or early autumn. They must be kept watered at all seasons, but, of course, less will be required in the winter than in the summer. Oncidiums need much the same compost, with the addition of a little fine charcoal. Repotting should, as a rule, be done soon after the flowers are over. Many of them will thrive under much the same conditions as the Odontoglossums, while some need more heat.

MISCELLANEOUS.

STERILISING SOIL (F. P.).—Any method by which you can raise the temperature of the soil to about 180° or over will serve to sterilise it so far as to kill eelworms and most of the other pests of greenhouse plants. It may be baked in an oven or heated by placing red-hot iron plates or bricks on the soil heap, but the best means of doing it is to drive steam into it. An apparatus fashioned like a fish-kettle, with a perforated false bottom on which the soil to be treated rests over water that can be heated to boiling point, the steam being retained by a cover fitting close, would probably serve your purpose as well as anything if only a small quantity of soil is to be dealt with.

SOCIETIES.

BIRMINGHAM AND DISTRICT GARDENERS' ASSOCIATION.

THE scriptural reference to "the highest and lowest seats in the room" was the Rev. Hilderic Friend's jocular opening remark at Birmingham on January 25, for, curiously enough, so close to him were the only two vacant seats that the comparison was most appropriate. "Garden Worms: Are They Friends or Foes?" constituted this first paper to the association, and, apart from its excellent scientific treatment, it practically covered a hitherto unexploited subject with many who were present. Until within quite recent years people, whenever they discovered, picked up or examined earthworms, invariably spoke of them all as Lumbricus terrestris, it being only of late that the discovery of the variation in species has been made. Darwin, perhaps one of the first to interest himself in worms, had assumed eight to ten kinds to be existing; but the matter only stood at that when the speaker himself commenced his own investigations, and his addition to the former list so far made the recognised species now to be forty-two in all. It is, however, certain that at least five times this number actually exist. The purple blue coloured worm in some gardens, the ruddy bright; and, say, steel blue in another, all denote variety of species. By inspection of the girdle, an interesting part of the worm's egg case—not, as is fallaciously supposed, the part where it has at some time or other been cut—the pores on the segments will disclose, as in the case of Lumbricus rubellus, the genus to which it belongs. Generally speaking, worms may be defined in the three groups Lumbricidae, Enchytraidae and Tubificidae, and no fewer than forty varieties are included in the Lumbricidae, those which without exception are in truth useful in the garden in breaking down decadent vegetation, sweetening the soil or attacking fermented manure. The Enchytraide, or smaller white worm, is guilty of ravages to

which grave charges may be made. During the past few years many new names have been added to them, and one instance of dire havoc being wrought on an Aster-bed was mentioned. In fact, all in this class are very dangerous unless their depredations are effectually checked. The Tubificidae are inhabitants of the water. They possess a tube and are bright red in colour. Although our acquaintance with worms is only yet in its infancy, science has already pronounced them as possessing a brain, an elaborate, highly sensitive and complex organic structure, and hermaphrodite in nature. Hearty applause was accorded for the lecture at the conclusion, and a vote of thanks also was proposed by Mr. W. Jones and seconded by Mr. A. R. Brown.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

THE annual meeting of the above association was held in the Parish Room, Wargrave, on Wednesday evening, January 13, under the chairmanship of the president, H. F. Nicholl, Esq., J.P. The Rev. S. M. Winter (Vicar of Wargrave), a vice-president, was also present, in addition to a good number of members. The election of officers for the ensuing twelve months resulted in Mr. R. Doe, gardener to Sir Charles Henry, Bart., M.P., being chosen as chairman; Mr. P. Wiseman, of Messrs. Waterer, Sons and Crisp, as vice-chairman; and the following as committee: Messrs. Batchelor, Gray, Haskett, Irvin, Richardson, Scott and Stephens. Mr. H. Coleby was re-elected hon. secretary and treasurer. The annual report and balance-sheet were considered extremely satisfactory, notwithstanding the critical period through which the country has been passing. Twenty-one of the younger members have joined His Majesty's Forces, but others have taken their places in the ranks of the society, so that there has been only a net decrease of two during the year. Several other matters of interest were dealt with before the meeting closed with votes of thanks.

HIGHCLIFFE GARDENERS' ASSOCIATION.

At the annual meeting of the members of this society, all the officers were re-elected for the year 1915. Cordial votes of thanks were passed to the president, E. Huntly Hooper, Esq., J.P.; the hon. secretary, Mr. A. Stephens; the assistant-secretary, Mr. W. Weaver; and the librarian, Mr. F. Cook, for the good work done by them during the past year. The society intends to hold two exhibitions this year, one at midsummer and one in the autumn. A substantial sum was raised, through the holding of the autumn show, for the benefit of the Prince of Wales' National Relief Fund, and now the members propose to include classes for cottagers in their 1915 prize schedules, so as

to encourage a wider interest in gardening in the district. The programme for the half-year ending June 6 is a very interesting one, and deals with important subjects. The staff teacher, Mr. Glead of the Hampshire County Council, is to give two lectures, and Mr. Montagu C. Allwood, Wivelsfield Nurseries, Hayward's Heath, a lantern lecture on "The Culture of Carnations (Indoors and Out)." Mr. W. Weaver was the winner of the President's silver medal in the Points Class during the year 1914.

DUMFRIES AND GALLOWAY GARDENERS' ASSOCIATION.

THIS association held its ordinary meeting in the Wesley Hall, Buccleuch Street, Dumfries, on January 23. There was a good attendance, with Mr. S. Arnott in the chair. After the usual formal business the chairman introduced the lecturer for the evening, Mr. John B. Crichton, The Gardens, Kinmount, Annan, who gave a capital paper on "Gardeners' Peculiarities." The scope of the paper included many comments on different classes of horticulturists, such as apprentices, journeymen, foremen, head-gardeners, nurserymen and nurserymen's travellers. It was written in a delightfully humorous vein and full of quips and anecdotes, with the result that it held the close attention of the audience during its duration, and was followed by hearty applause. It was not devoid of sound advice, and much of this, conveyed in a witty way, was well worthy of reflection from those present. A short but appreciative discussion, taken part in by several members, followed, and Mr. Crichton received a hearty vote of thanks.

CHELMSFORD AND DISTRICT GARDENERS' ASSOCIATION.

THE seventh meeting of the association was held in the East Anglian Institute of Agriculture on Friday, the 22nd ult. Mr. R. H. Currie presided over about thirty members. Mr. R. M. Wilson, Principal of the institute, gave a most interesting and instructive lecture on "Soil Moisture." The lecturer dealt with his subject in a scientific manner, and showed how the soil was made up of numbers of minute grains, and how, under ordinary conditions, these grains were surrounded by a film of water. It was pointed out that the greater proportion of the rainfall fell during the winter months, and therefore crops, as a rule, never obtained the maximum amount of water that they required during the growing period. Cultural operations, such as ploughing, rolling, mulching and surface cultivating, were fully explained, and it was shown how these various operations tended to the conservation of soil moisture. Mr. Wilson illustrated his remarks by various experiments. At the conclusion of the discussion

a hearty vote of thanks was accorded Mr. Wilson for his most interesting lecture. Mr. Currie was also accorded a vote of thanks for kindly taking the chair.

OBITUARY.

WILLIAM TAYLOR.

WE learn with regret of the death of Mr. William Taylor, stationmaster at Dalmellington, and an ardent amateur horticulturist, which took place on January 26. Mr. Taylor, who was sixty years of age, was for twenty-five years in the service of the Glasgow and South Western Railway Company, and went from Ayr to Dalmellington about nine years ago. His love of horticulture soon found scope at that place, and he transformed the grounds into a beautiful garden, which received the highest awards at the annual competition. Mr. Taylor was much esteemed in private life as well as in his official work. He is survived by Mrs. Taylor and a young family.

JAMES CHAPMAN.

STIRLINGSHIRE has lost one of its oldest and most respected market gardeners by the recent death of Mr. James Chapman, Candie, near Grange-mouth. Mr. Chapman was in his ninety-fourth year, and had carried on business as a market gardener for the lengthened period of sixty-six years. He was a skilled horticulturist, and his produce was of the highest quality. Mr. Chapman was much esteemed in his private and public capacities, and his knowledge of his calling and the integrity of his character frequently led to his appointment as a judge at flower shows over a wide area.

ECONOMY IN THE GARDEN

WE offer all the choicest stocks of **Vegetable and Flower Seeds** at the **Lowest Profitable Prices**. We feel confident that many amateurs now paying from 25 to 50 per cent. more than we charge would, if they gave us a trial, find the results equally good, and they would have the surplus to spend in other directions. We quote below a few specialities.

Fully Illustrated Catalogue Free on application.

PEAS

Gradus 8d., Thos. Laxton 9d., Reading Wonder 1/-, Triumph 6d., Prince of Wales 6d., Autocrat 8d., Prizewinner 1/-, Capt. Cuttle 9d., Little Marvel 8d., The Gladstone 8d.

ALL PER PINT.

All the best **BEETS** from **6d. to 1/-** per oz.

" **CABBAGES** **6d. to 8d.** per oz., **2d.** per pkt.

" **LETTUCES** from **6d. to 1/-** per oz., **2d.** and **3d.** per pkt.

Nearly all the best **ONIONS** **6d. to 2/-** per oz.

RADISHES **2d. to 3d.** per oz.

The BEST TOMATOES

Best of All (Sutton), the best exhibition variety, **6d.** and **1/-** per packet.

Sunrise (Carter's), the heaviest cropper in cultivation; fruit perfect in shape and excellent in flavour, **3d.** and **6d.** per packet.

Buck's Tresco (New), saved from selected fruits, **6d.** and **1/-** per packet.

Up-to-Date, very short jointed in habit and extremely prolific. Fruit smooth, medium size, excellent quality, **3d.** and **6d.** per packet.

Kondine Red (Holmes), a wonderful cropper, **6d.** and **1/-** per packet.

ALL THE ABOVE ARE SAVED FROM SELECTED FRUITS.

CHOICE PRIMULAS

We have a magnificent strain of these. The seed is saved in our own houses, with the utmost care. All seed is 1914 crop, and certain to grow if it has a fair chance. Large flowered varieties—**Brilliant King**, **1/-** per pkt.; **Cannell's Pink**, **1/-** per pkt.; **Mrs. Robt. Cannell**, **1/-** per pkt.; **Pink Perfection**, **1/-** per pkt.; **The Duchess**, **1/-** per pkt.; **White Perfection**, **1/-** per pkt.; Also mixed from above varieties, **1/-** per pkt. **Stellata Mont Blanc**, and finest mixed, **1/-** per pkt. The packets contain about 120 seeds.

A Fine Selection of Seed Potatoes—Scotch Grown.

J. R. PEARSON & SONS, "The Nurseries,"
LOWDHAM, NOTTS. Established 1782.

THE GARDEN.

No. 2256.—VOL. LXXIX.

FEBRUARY 13, 1915.

NOTES OF THE WEEK.

Treatment of Ferns in Pots.—The usual condition of some species of Ferns in pots at this season of the year, owing to the removal of fronds, is not very flourishing, therefore water should be applied with judgment for a few weeks, only giving them sufficient to prevent the drooping of the existing fronds. Ferns rested in this way throw up more young fronds and grow with greater vigour than when the opposite course is adopted. As soon as plants of *Adiantum cuneatum* are cut over, place them in a temperature of 50°, and keep them there till new growth commences; they should then be potted on, or divided if they are getting larger than is required.

A Noble Oak.

Quercus Mirbeckii is one of the most distinct and ornamental of the many kinds of Oak, and it is a species to remember when a choice is being made of large-growing trees for park or garden decoration. A native of North Africa and certain parts of South-West Europe, particularly Portugal, it sometimes exceeds 100 feet in height, with a large trunk, and is conspicuous by reason of its large leaves, which are in some seasons almost evergreen and rarely fall before January. The leaves are often 5 inches to 7 inches long and 2 inches to 3½ inches wide, with regular and rather deeply lobed margins. It gives good results when planted under the same conditions as the common Oak, requiring deep and really good soil to ensure the best development.

A Beautiful Camellia.—The illustration on this page represents flowers of *Camellia reticulata*, one of the most beautiful members of the family, and one that deserves to be better known. As will be seen, the flowers are not of that stiff, formal outline that is usually associated with Camellias, and therein lies their principal charm. The blossoms are a pleasing shade of bright soft rose, and open in a cool greenhouse during the early months of the year. This species is a native of China,

whence it was introduced to this country nearly a century ago. If planted out in a border, it will make a large bush 8 feet or more in height, but it is also suitable for growing as a smaller plant in pots.

Presentation to Mr. George Bunyard.—Owing to failing health, Mr. George Bunyard, V.M.H., felt it necessary a few weeks ago to resign the chairmanship of the Royal Horticultural Society's fruit and vegetable committee, of which he has been a member for thirty-four years and chairman for fourteen years. His fellow-members of that committee have presented him with an illuminated address, together with a diamond

is *Calluna vulgaris cuprea*, though one usually finds it labelled in gardens as *Erica vulgaris cuprea*. A good breadth of it planted on a gently sloping bank would create quite a bright, warm effect during the winter months, and it is also beautiful in late summer when its purple flowers open. Like other varieties of Ling, it appreciates well-drained and rather sandy soil that contains a good amount of humus.

The Glory of the Snow.—This is the popular name given to a beautiful little blue flower that opens during the early days of spring, when vegetation generally is awakening from its winter slumber. Botanically the plant is known as *Chionodoxa Luciliae*. There is an even more pleasing variety known as *sardensis*. This is deep blue in colour, with cinnamon red flower-stems. The blossoms open just a little later than those of *Luciliae*. It is a very charming flower for planting in small colonies in the rock garden or for the more prominent places among shrubs. Seeds are produced in abundance, and if allowed to ripen and fall, germinate very freely.

Rhododendron nobleanum Flowering Well.—The mild weather of the present winter has been favourable to the development of the flowers of this bright-coloured *Rhododendron*, and

A FLOWERING SPRAY OF *CAMELLIA RETICULATA*, A NATIVE OF CHINA WITH ROSE-COLOURED BLOSSOMS.

and sapphire gold pin, as a token of the high esteem in which he was held by them all. The address and pin were displayed at the meeting of the committee held on Tuesday of last week, and were presented to Mr. Bunyard by a deputation on the following Thursday. Mr. C. G. A. Nix has been appointed the new chairman of the fruit and vegetable committee.

The Copper-leaved Ling or Heather.—In the Heath garden just now the Copper-leaved Ling is an attractive and interesting plant, by reason of its rich red-bronze foliage and tips of the shoots. It is a medium tall variety, though on poor soil it remains dwarf for years. Its full botanical name

several bushes have been noted in good condition between Christmas and the present date at Kew and in other gardens. It is a very old garden plant, for it is said to have been raised as long ago as 1832 in the Knap Hill Nursery by crossing *R. arboreum* and *R. caucasicum*, and it has held its own among other kinds throughout the time, being still popular in many places. In Cornish gardens it makes a distinct winter feature, while it is also grown extensively in some parts of the North of England, its rosy red flowers expanding any time between November and March. It is, without exception, the most valuable hybrid *Rhododendron* for early forcing.

HOME-GROWN VEGETABLES AND OUR FOOD SUPPLY.

The article that appeared under this heading in our last issue has created a considerable amount of interest, and we publish below a selection of letters that we have received on the subject. In addition to the letters that have been sent for publication, we have received a number from some of the highest Government officials, Members of Parliament, and other public men. Invariably the writers of these letters cordially endorse our remarks, but, holding the position they do, they not unnaturally mark their communications "private."

I AM much pleased to see your excellent and timely article in *THE GARDEN* for February 6, pointing out the national importance of everyone doing their utmost to increase our supplies of home-grown vegetables. At this juncture to do so is not only a patriotic action, but one which, having regard to the inevitable tendency of all foodstuffs to rise in price, should be pecuniarily profitable. I sincerely trust that the various horticultural societies will aid your propaganda; they certainly should. Without waiting for your advice, I have already arranged to utilise all available land possible at Aldenham for this purpose.

Aldenham House, Elstree. VICARY GIBBS.

In reference to the editorial article which appeared on page 63 of last week's issue, everyone doubtless will agree that we cannot very well have too many Potatoes and other vegetables at the present time. I would strongly advise all cottagers to grow all they can of kinds that are likely to be most useful for food, since bacon, cheese, bread, butter and Potatoes, which together may be taken to be their main food in normal times, will be dearer. The question of growing more for hospital consumption or for sending to the Fleet or for kindred purposes is different, and it seems to me that if local societies are to take up this work, co-ordination and co-operation are very necessary in order that the distribution may be arranged to the best advantage. JOSEPH JACOB.

I was delighted to read the article on "Home-grown Vegetables and Our Food Supply" in your issue of last week, and very much hope that you will enlist wide and prominent support for your excellent suggestions. With regard to the good work which could be done by the various horticultural societies throughout the country, I am entirely with you, and I have already approached the secretary of our local horticultural society, asking him to place the article before his committee. I feel that it is impossible to treat the question of our vegetable supply for the coming year too seriously. Surely there can be no doubt that, owing to the constantly increasing prices of meat and bread, the demand for vegetables will be an ever-increasing one, and I unhesitatingly state that it is both patriotic and business-like for every one of us to do all we can to increase the growth of vegetables in every possible way. May I make what I hope you will think is a practical suggestion? Could you not send out to the secretary of every horticultural society in the country a copy of your article and ask him to place this matter on the agenda paper for his next meeting? [This, as far as possible, shall be done.—ED.] J. ALLAN RAMSAY.

THE appeal you have made for co-operation among horticulturists to grow vegetables for the hospitals is a most timely one. We have, unfortunately, before us a great and pressing need.

We cannot hide from ourselves that in such a gigantic struggle the number of wounded will be very great. An ample supply of vegetables fresh from the ground of English gardens may prove the saving of many lives and the alleviation of much suffering. Although each garden may only be able to contribute a little, many of these littles will mean much when all is told. Your idea of combination by local societies to collect and send in the produce as it is ready will certainly make the work easier and less costly all round. If local societies would accept your suggestion and collect orders from their members for the produce to be grown upon your plan, I am sure that not only our own association, but all seedsmen of standing would gladly co-operate in quoting wholesale prices. The difference between wholesale prices and the much higher figures required for small lots does not represent, as is sometimes supposed, an increased profit to the supplier. The difference is lost in expenses of labour, packages and railway carriage. You suggest that technical hints might be distributed among the members of the horticultural societies, who would undertake to grow surplus vegetables. We have, as you are well aware, published many penny garden books containing information for the use of small holders, allotment holders and owners of small gardens. One of these by the veteran horticulturist, Mr. John Wright, V.M.H., on "Cropping Allotments," would, I think, be very useful to the growers, and we should be happy to make grants, through yourself, of copies to be distributed, to a reasonable amount.

EDWARD OWEN GREENING.
92, Long Acre, London, W.C.

I AM quite in accord with the very practical article in *THE GARDEN* of February 6. I reply to it, strongly supporting the same, and will use similar headings in doing so, as in the article in question.

Co-operation Needed.—We had during the past autumn some practical experience of the beneficent effects of the use of surplus vegetables. For several weeks we sent such from these gardens to the London hospitals and homes of refuge. I can testify to the appreciation of the recipients of these. It is not so much a question of those in large establishments. These can, and will, help, I have no doubt, and to the best of their ability; but those with smaller gardens can help too. It is in this that co-operation will be found to work well. With this I cordially agree in the suggestions made.

Horticultural Societies Should Help.—At such a time as the present all horticultural societies should rise to the occasion and do all that lies in their power to assist in their immediate locality by inducing a spirit of emulation among its own members and others within their reach. True, the prize schedule in many societies is this year being abandoned. I do not think personally that this should arise. It shows a tone of

despondency. Why not rise to the occasion and endeavour to encourage the extended culture of such vegetables (and flowers too) as will prove to be of use in the way indicated? In the case of such societies as make a point of good vegetable exhibits, prizes might be offered for the best crops on the ground that are suitable for the calls of the moment. Others that make a feature of flowers can also help by sending them to the hospitals, care being taken to avoid overlapping.

How Assistance Can be Rendered.—Local committees might do a great deal towards encouraging this new departure in cultivation. The advice of experts should be sought as to the best methods of procedure. What strikes me is this: A point should be made of getting the utmost off the ground at such a time. By this I mean make a feature of first-early vegetables to a great extent, e.g., early Peas, early Carrots, early Turnips and the like; early Lettuce also, brought on under cloches if needs be; early Marrows by the same means. By adopting these methods much of the ground can be double cropped. Do not adhere too much to the rule of thumb practice, but rather try to make every available yard of ground yield something that will in due course prove to be useful. Parsley is ever welcome; so are such herbs as Thyme, Mint, Marjoram, Savory, &c. I know that salads are welcomed; hence, in addition to the Lettuce I have named, there are Radishes, Cress of various kinds, and later on Tomatoes from early raised plants. The Turnip-rooted Beet is very useful indeed for early use for salads. I found Cucumbers, too, were most acceptable last autumn.

The Supply of Seeds.—This would apply more particularly to societies which ordered seeds and then distributed them among their members. The hint I have given as to early varieties could be taken into consideration in giving these orders. It is not in any sense essential to launch out in the purchase of expensive varieties, while new varieties should be given the go-by at such times. The seedsmen of repute—and their name is legion—would, I feel, be only too glad to give advice as to the best varieties to purchase, while I have no doubt a liberal discount might be anticipated on payment of the account being made.

The Collection of Surplus Vegetables.—This is a matter where horticultural societies should help. By having a small committee, it is quite possible to do a deal in this way. Small quantities could be collected and then packed in one hamper. (In doing this enclose a "returned empty" label. I find this pays in all cases.)

Surplus Plants for Cropping.—I know that numbers were distributed last autumn by the Royal Horticultural Society's influence. This can be done again this season by societies all over the country if taken up in time. There will be many surplus plants available during the season. Rather than let these spoil, by all means use them.

JAMES HUDSON, V.M.H.
Gunnersbury House Gardens.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Outdoor Flowers in Midwinter.—Regarding your note on outdoor flowers in midwinter, page 37, issue January 23, you might have added the Winter Heliotrope (*Petasites fragrans*). It has been flowering freely this winter.—W. LILICO.

Cuttings with "Heels."—Is it not the case that the reason for taking cuttings with "heels" is that it prevents bleeding? My father, who was a successful Geranium-grower, always laid his cuttings out in the sun until the cut ends had dried, and he showed me that cuttings put in the ground with a bleeding end were very apt to rot off. My experience is that it is generally best with all plants which are juicy and soft to let the cuttings wither a little before placing them in the ground. I wonder if Mr. Portman Dalton, who writes under this heading in your issue of January 30, has tried this.—THACKERAY TURNER.

Solanum ciliatum.—I was interested in seeing your illustration of *Solanum ciliatum* on page 56, issue January 30, having often wondered why I had never met the plant in England. Twenty-five years ago I saw bushes of it in Mr. Hanbury's beautiful gardens at La Mortola, beyond Mentone, and brought back one of the fruits, from which I raised a number of seedlings. We moved house, however, or something, and they never arrived at more than the seedling stage, and I cannot remember their ultimate fate. They are so easily started, however, that they would probably do well planted out against a south wall, like Tomatoes, especially in a summer like that of last year.—A. LA T.

Funkia subcordata alba odorata.—I am much obliged to "E. M." for his note on page 27, in the issue of January 16, in response to my enquiry under the above heading. I am also much obliged to Mr. James Adison, The Gardens, Castle Mary, Cloyne, County Cork, who wrote me, giving the result of his experience with the white *Funkia*, which experience goes to show that while it usually flowers well when grown in a deep, moist soil, it is not quite satisfactory in some seasons. Although I obtained the plant, named as above, from a leading London firm, I am now convinced that it has been a misnomer, and that our plant is really *Funkia subcordata grandiflora*, as suggested by "E. M." In Nicholson's "Dictionary of Gardening" it is given as a distinct species under the name of *F. grandiflora*, but when referred to in the Supplement it is said to be "a form of subcordata." Other *Funkias* succeed well in our moist soil, so I must try my hitherto disappointing plant in a new environment, and may some day record the result in these pages.—CHARLES COMFORT.

A Hedge of Sorts.—I see in your issue of January 9 an enquiry in your "Correspondence" by "Anne Amateur" re "A Hedge of Sorts." I suggest here a few "sorts" which I should be pleased if you would publish or convey for "Anne Amateur's" perusal. A good Crab is *Pyrus Maulei*, dwarf, and allied to *P. japonica*; flowers brick red, fruit used for preserving. Others really better in flowers but not so in fruit are *P. thianschanica*, *P. baccata* and *P. cerasifera* (Cherry Crab). A good Maple is *Acer rubrum*, scarlet or crimson flowers and red keys, the extremities of the branches deeply tinged with red in early spring; very ornamental. Other sorts are *A. campestre*, *A. palmatum* (*A. polymorphum*), *A. pinnatifidum*, *A. crispum*, *A. roseo-marginatum*

and *A. purpureum*. I also think *Berberis* ought not to be left out. Two good ones are *B. Darwinii*, yellow flowers in early spring and again in the autumn, and *B. empetrifolia*, yellow flowers, December to March.—H. S. P., Wroxham.

Daffodils for the Garden.—Mr. G. L. Wilson's letter under this heading in your issue of January 30 tempts me to offer a few more remarks on the variety King Alfred, which he recommends everybody to try very hard to grow. I meant to have added a sentence in my former letter when speaking of this variety, advising those who must have it for exhibition purposes to make sure that they get their stock from those who had grown it in the South-Western Counties of England, the Welsh seacoast, or from the bulb-growing districts in Ireland, which are practically the only places in the British Isles where it will thrive and bloom well year after year. Mr. Wilson I see lives in County Antrim, and even he has had some poor experience of it, and in a sense his county address goes to prove my point. I must repeat, however,

properties of the variety, but, until it can be bought at a price very much under 21s. a dozen, I advise all those who are outside the sphere of its particular favours to confine themselves to well-known good doers.—A SMALL AMATEUR.

Iris stylosa.—I have been waiting each week to see if any of your correspondents would write to you remarking on the phenomenal blooming of *Iris stylosa* this winter, but, as none has done so, I think perhaps it may be of interest to give you the results of my experience. Since before Christmas I have been picking an average of forty to fifty blooms every two days off about a dozen plants. Some days I have gathered as many as a hundred blossoms. The clumps are scattered about in every variety of aspect and soil, and all have done equally well, including the beautiful white variety of the type. Some are planted in wet, sour ground facing south (these were given mortar rubble when planted some years ago), one clump is in a shady but dry corner facing east, some are on the poor soil at the base of a rocky

FLOWERS AND FOLIAGE OF IRIS STYLOSA, A CHARMING WINTER-FLOWERING SPECIES.

that King Alfred has been tried both in Middlesex and Surrey for the last ten years and more, and has been found almost impossible to keep in good condition. When I first got a bulb of it from an old florist friend of mine who lived in Surrey, he informed me that it had done very badly with him. With me the precious bulb was, of course, a poor thing in growth the first year, and as it was at that time listed at £4 4s. or £5 5s., I must have been struggling to get it to do better for seven or eight years at least. I have tried to grow it in a considerable depth of maiden loam, and in such even under standard fruit trees, but all to no purpose. During recent years I got twelve bulbs from Cornwall, and these did fairly well the first year of blooming, but the disease had got them by the second year. I have come to the conclusion, therefore, that the trouble is more a matter of climate than of soil; hence I adhere to the remarks I made about it in my former letter in your issue of January 23. I agree with Mr. Wilson as to the fine exhibition

cliff, where they are growing practically in powdered freestone, some are in garden beds. Those in the latter run more to leaf, though the flowers are also abundant. Those on poor soil have poor foliage, but masses of flowers. Mr. Rickatson Dykes, in his excellent little book on Irises, classes *I. stylosa* among those difficult to flower, and no doubt this is the case in some soils. My experience is that after a hot summer like the last the flowers are abundant, whatever the weather may prove during the blossoming period. I had much the same results after the hot summer of 1911, when I also sent you a few notes on the subject. During these cold, wet weeks the exquisite blooms of this lovely *Iris* have helped much to cheer one in the otherwise depressing state of the garden, and I feel sure many more people would grow *I. stylosa* if they realised its unique beauty as a hardy winter-flowering plant. I may also mention that I have already had a few blooms from the usually much later-flowering variety *speciosa*.—S. PRENDERGAST, Windcliffe, Nilton-Undercliff, Isle of Wight.

SOME HARDY LILIES.—VII.

BY SIR HERBERT MAXWELL, BART.

SUB-GENUS CARDIOCRINUM.

Lilium giganteum, the Giant Lily, is well named, for it is the noblest in stature and amplest in foliage of all the genus, besides producing flowers of great beauty and fragrance. It is perfectly hardy in all parts of the British Isles; I have known it come unharmed through a temperature below zero Fahrenheit without the slightest protection, which is the more remarkable because it grows with the apex of its huge bulb flush with the soil-level. Of the many hundreds I have raised from seed, I have never known one to suffer injury from disease or parasite; even rabbits avoid the glistening foliage. Why, then, have so many amateurs met with disappointment in trying to establish it? The reason is not far to seek; it is found in the deplorable condition in which the bulbs are offered for sale, with the long, fleshy roots withered or rubbed off. When they arrive in that state, the large flowering bulbs are scarcely likely to recover, though the smaller ones may be nursed back into vigour in a cold frame. Once a bulb has produced its ample foliage, there is no difficulty about propagating it to any extent, for in time it will send up its huge flowering shaft, to be followed by a profusion of seeds, whence an ample stock may be raised. I speak, however, only from experience of the seed of Himalayan plants; the Giant Lily is also a native of China, and I am informed that the seed of plants from that country is not fertile. The seeds should be sown in boxes with loam, sand and leaf-mould or peat; most of them will lie till the second season before germinating, when a dense crop will spring up. The seedlings should be pricked out as soon as they can be handled, preferably in a cold frame, lest frost forces them out of the ground; but after a season under glass they may be set in the open, care being taken all along not to let them suffer from excessive sunshine. Mr. Weatherby, in his excellent "Practical Guide," states that the bulbs will flower in from four to six years from seed. That is a sanguine estimate; I have found that it takes seven or eight years from sowing to produce a flowering bulb. Luckily, there is a far more speedy method of propagation. After flowering, the huge bulb, sometimes weighing more than two pounds, dies, but not before throwing out a numerous progeny of smaller bulbs. Some of these will be found large enough to produce flowering stems in two years, which they will do if left beside their dead parent, the smaller ones waiting to start till their elder brothers have flowered and died in their turn. To increase the stock, it is only necessary to raise the clump in October, and to plant out the young bulbs separately. A plant of such robust habit as the Giant Lily exacts, and deserves, generous treatment.

Before planting the bulb, a hole at least 1 foot deep should be dug in loamy soil, in a position well drained, but the reverse of dry. Into the hole enough loam, mixed with peat or leaf-mould, should be put as will allow the bulb to rest with its pointed top just under the surface when the hole is filled in; for it is a peculiarity of this Lily that, although it sends out strong roots around the base of the flowering stem, as well as those from the base of the bulb, it does not agree with deep planting, such as ordinary stem-rooting species require. After growth begins and the plant is well established, one can hardly treat it too

a green column, which, as it lengthens throughout May and June, throws out fresh leaves in a regular spiral, lessening in size towards the top. Finally, having attained a height of 8 feet to 10 feet, the long green flower-buds appear, erect at first; then slanting to the horizontal, whitening, and at last opening one by one to any number between a dozen and a score on a single stem. The flowers are creamy white, broadly streaked with purplish maroon within, and diffuse a delicious fragrance. It is essential for the production of such a noble structure that it be sheltered from strong winds. The stem, often 9 inches in circumference at the

base, is stalwart enough to disdain staking; but the flowers, though of great substance, may be shattered in a summer storm. Moreover, wind exposure prevents the stems from rising to their full height, and stature is the crowning glory of the Giant Lily. When the flowers fall, the seed-vessels begin to swell, and continue to do so till each reaches the dimensions of a hen's egg. Standing like green candelabra, the stems remain very decorative till the end of November. Then comes the propagator's opportunity. He may not only save a bountiful harvest of seed, but secure a great number of young bulbs. The old flowering bulb will have disappeared by this time, its substance having been expended in throwing up the flowering stem. Seize that stem and pull it up; it will yield readily, and bring away among its roots half-a-dozen or so of small bulbs, leaving in the soil a number of others, which should be allowed to remain there, after receiving a liberal mulch, to flower in their turn in the following or some subsequent summer. Let the bulbs once be established in rich, deep soil, and the Giant Lily will prove as easy to manage as any Larkspur or Rudbeckia; but if it is desired to have it at its best, it must be generously treated. There is little danger of giving it too much nourishment. My own garden is situated near a large lake which swarms with pike, upon which we make occasional raids with a net in the interest of wild ducklings—favourite tit-bits in pike circles. Fish manure is very stimulating. There is nothing the Giant Lily appreciates more keenly than an eight or ten pound jack laid to rot under its big radical leaves.

Three or four years ago I offered to supply (gratuitously, of course) a

well-known firm in the North with a quantity of seed of the Giant Lily (*L. giganteum*), gathered from plants which I had myself raised from seed. The offer was declined; albeit in a catalogue for 1913 now before me, bulbs of this Lily are priced from 2s. 6d. to 15s. each, and generally arrive from abroad in a hopeless condition, owing to the long, fleshy roots having withered. Had my offer been accepted by this firm, they might by this time have had a valuable stock of hundreds of healthy bulbs to put on the market, instead of the debilitated imported stuff which is the cause of so much disappointment.

A BEAUTIFUL GROUPING OF LILIUM GIGANTEUM IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY.

generously. A heavy mulch of cow-manure is not a pretty object during the winter months, but it is soon screened out of sight when the splendid, cordate, radical leaves, of a glistening grass green, develop in spring. These are very ornamental in themselves. They are proof against all but extraordinary frost in spring, and I have never known rabbits, slugs or any other unhallowed creature to molest them.

Next follows the excitement of detecting which of these royal masses of foliage is to send up a flowering stem. The centre of a clump thickens, rises and develops into

UNDESIRABLE PLANTS FOR THE ROCK GARDEN.

THIS text has been suggested by a correspondent, who writes: "Would it not be worth while for you to write an article on plants which gardeners should avoid?" and the obvious affirmative reply is contained in the accompanying remarks. Doubtless there are garden "undesirables" as there are also those of the other class, and, the twain being of a parasitic nature, merit drastic measures if they are to be driven from our midst. Doubtless, too, with a desire from time to time to give readers the best a garden may contain—one eminent writer declared years ago that the "best of everything was quite good enough for him"—the "undesirables" have been too long overlooked or ignored, notwithstanding that their pest-like character or weediness should long ago have entitled them to a place in a never-to-be-completed *index expurgatorius*. I say "never to be completed" advisedly, inasmuch as one's experience in such matters continues to grow, quite independently of the way in which certain plants are influenced by local conditions. Bearing this latter in mind, actual experience will always be the best guide, and must ever take precedence of orthodox. Testimony to this end may be found in the way certain garden weeds infest one locality while entirely absent in another, the same principle having its parallel among cultivated plants. Hence, as I have written elsewhere, "the weed of one soil is not necessarily so of all," though such things as *Calystegia* and *Convolvulus althæoides* are usually particularly troublesome on all chalk soils, and should be guarded against accordingly.

In the rock garden an "undesirable" becomes all the more so by reason of the shelter the rocks afford, and roots or stems penetrating every crack or cranny are in an impregnable fortress of their own, from which it is almost impossible to drive them or even starve them out. Against all such, of course, the gardener should be warned. The more pernicious weed pests of the garden, Coltsfoot (*Tussilago*), Couch Grass, Bindweed and the terrible Goutweed (*Ægopodium*), every gardener will guard against, though there is danger at times, consequent upon the use of roadside sweepings—though less frequently employed to-day than formerly—of some of them getting into the garden through the medium of seeds or roots. Should such ensue, drastic measures must be resorted to at once, since the first loss will undoubtedly be the least. Delay in such a case is dangerous. It is vexatious, too, while feeble efforts to oust the pest are continuous and, in the end, costly; hence none should hesitate about moving rock or plant, or both, in order to beard the lion in its den. It is in these circumstances, therefore, that I warn readers against the following plants, some of which, while having no

right in the rock garden at all, get there in some inexplicable way, to the worry and discomfiture of the gardener: *Achillea Millefolium*, in any form; *Asperula odorata*; *Calystegias*, all, particularly in chalk soils; *Campanula Rapunculus*; *Cerastium tomentosum* and *C. Biebersteinii*, the last the worst of the two; *Convolvulus althæoides*, especially on chalk soils; *Convallaria varia*; *Crucianella stylosa*, occasionally, though easily kept within bounds; *Euphorbia Cyparissias*; *Galiums*, all; *Hieracium aurantiacum*; *Muscari*, often because of the numerous bulb progeny; *Oxalis corniculata* and perhaps other species; *Sedum spurium*, the most aggressive, perhaps, of the whole race, rooting into every crevice and, particularly in cool places, overwhelming all; with *Vancouveria hexandra* and *Vincas* generally. These are among the worst known to me. Doubtless there are others. If so, those readers of THE GARDEN who know of "the enemy in our

SWEET PEAS FOR GARDEN DECORATION.

FOR its fragrance, its free-flowering nature, and hardy constitution that enables it to grow in the town garden almost as well as in that situated in the country, the Sweet Pea is without exception the most popular as well as the most useful annual of to-day. For garden decoration it is quite indispensable, as, no matter where it may be planted, it can never be unsightly, while for cutting it is seldom that one has too many, as the demand is unceasing for this glorious flower, and the longer the season is prolonged, the more are the flowers appreciated. In order, as far as possible, to obtain a long season of flowering, it is usual to make three sowings—the first towards the end of September, the second early in

FOTHERGILLA MAJOR, A BEAUTIFUL AND INTERESTING HARDY SPRING-FLOWERING SHRUB.

midst" should not fail to communicate with the Editor without delay.

E. H. J.

A LITTLE-KNOWN HARDY SHRUB (FOTHERGILLA MAJOR).

WHEN better known, this free-flowering shrub is destined to hold a prominent place in the gardens of this country. Singularly enough, it was known in this country over a century ago, and was figured, in 1811, in the *Botanical Magazine*. At that time, however, comparatively little interest was displayed in rare shrubs, and *Fothergilla major* was soon lost to cultivation. For its reintroduction we are indebted to Professor Sargeant, who sent it to Kew about twelve years ago. So far as soil is concerned, this plant does well in a sandy loam to which peat and leaf-mould have been freely added.

C. Q.

February, and the last about the middle of March.

Spring Sowing.—As the former is now out of the question, the beginner must contrive to get the best results from the last two dates. The earliest sowing is made in pots, the question of size being an open one. For the purpose in hand a convenient size is 5 inches. The pots should be perfectly clean and well drained. A suitable compost consists of four parts good loam to one part each of leaf-mould and dried stable manure. The ingredients should be passed through a fine sieve, and a dash of sharp sand or old lime rubble added to keep the whole porous. Avoid sowing too thickly; seven seeds in each pot are ample.

Treatment of Seedlings.—If a warm greenhouse is available, germination will take place rapidly; but as soon as the seedlings are noticeable, remove to a cold frame and endeavour to

promote a healthy growth by keeping them as cool as possible, so that they will experience no check when planted out in April. This method should give flowers early in June. Plants from the sowing made in the open in March will commence to flower about a month later and continue to do so as long as the weather remains open.

Soil Preparation.—Wherever the Sweet Peas are intended to flower, the soil should be thoroughly prepared for them in advance. In the majority of cases this, no doubt, has already been done; but where, so far this has not been possible, it is essential to the welfare of the plants that it be no longer delayed. To get the best return from a row it is necessary to trench the whole length of it for a width of not less than two yards, and during the process work in a liberal quantity of well-rotted manure, leaf-mould, wood-ashes and bone-meal. Should there be any turf available, the best place for it, along with the manure, is at the bottom of the trench, the other ingredients being put among the top soil. Excellent results may also be obtained by digging out a good wide trench the length of the row and filling it with rich soil; but it will be understood that unless it be made wide, the roots cannot experience the same freedom as in the above method. This applies with no less force to clumps that are to be planted in the shrubberies and borders, as everything depends on giving the roots a wide area to run in. If this is taking place throughout the season, there is never a shortage of superior flowers.

For the Outdoor Sowing it is perhaps advisable to choose the first opportunity when the soil is workable after March is in. The surface should be lightly forked up and left for a couple of hours to dry. Raking and drawing out a drill some two inches deep is then much easier. Avoid sowing too thickly, and choose the finest of the soil to cover the seeds.

Planting Out.—Early in April in average seasons is a suitable time to plant out those growing in pots. In this case, during the forking up of the soil, the opportunity should be taken to work in a sprinkling of superphosphate. In planting, avoid injury to the roots as much as possible, and if the soil is very dry, give a good watering with clear water. If the weather is at all genial, the plants will soon begin to make headway, and no time should be lost in giving them the necessary support.

Supports.—Where the time-honoured Pea-sticks are not to be had, the problem of what is best to use is no light one, as for garden decoration the exhibitor's method is no way out of the difficulty. Wire-netting of large mesh is used by many, with the desired results, for both rows and clumps. For the latter it is arranged in a rough circle by fastening it to five stout stakes. When it is used for rows, it is secured to tall stakes fixed some twelve feet apart. Among the advertised supports, the Simplicitas Netting is good, being easily fixed and very durable.

Varieties.—For the beginner anxious to grow the latest and best varieties, the following are worthy of note. Among them will be noted many exhibitors' favourites; but seeing there is no proof that such are unsuitable for garden purposes, there is no reason why one should not avail himself of the newer varieties and be up to date: Hercules, Thomas Stevenson, King White, Robert Sydenham, Agricola, King Manoel, Barbara, Melba, Mrs.

FLOWERING SHOOTS OF ACACIA DEALBATA, NOW BEING SOLD IN THE MARKET AS MIMOSA.

Cuthbertson, Mrs. C. W. Breadmore and May Campbell are all leading sorts; and Maud Holmes, Nubian, R. F. Felton, Elsie Herbert, Rosabelle, Etta Dyke, Clara Curtis, Nettie Jenkins, Countess Spencer and Edrom Beauty are all recognised as being among the best all-round varieties.

F. J. TOWNEND.
The Gardens, Brentwood, Moorgate, Rotherham.

AUSTRALIAN MIMOSAS (ACACIAS).

THE various Australian species of Acacia constitute an important group of greenhouse plants in most parts of the country, while in a few favoured counties they are hardy. In Devonshire, Cornwall and other

places with similar climatic conditions they develop to a great height, trees 40 feet high with trunks a foot in diameter being found in many gardens. Australia is particularly rich in species, and upwards of one hundred have been introduced at one period or another. Some of these possess little beauty until they have assumed the proportions of trees, while others are charming in a small state and bloom profusely when only a few inches high. They were possibly more popular as greenhouse plants a quarter of a century ago than they are to-day; but a considerable quantity are still cultivated, while in France one or two species are grown largely for cutting, branches being cut and forced into flower for the Paris and London markets, where they are sold under the name of Mimosa. The common name of Wattle is also applied to the Australian Acacias, the different species being distinguished by one or another prefix.

Where they will thrive out of doors they may be planted in groves or as isolated specimens. The taller-growing kinds, such as *A. dealbata* and *A. decussata*, quickly assume tree-like proportions, and are very beautiful in early spring when covered with their fluffy, yellow flowers. Several flowers compose a small round head, and a large number of these go to make up a good-sized panicle. Some of the smaller kinds grow into large bushes and are effective as evergreens in addition to their beauty as flowering shrubs. No more delightful sight can be wished for than a large tree of *A. armata* covered with dark green foliage and balls of golden blooms, while little difficulty is experienced in their cultivation once a plant becomes established. In these warmer counties it is possible to grow the majority of the introduced kinds outdoors, and in some gardens there are good collections.

Although it is the general practice to cultivate Acacias indoors as small pot plants, it is not in this way that the most satisfactory results are obtained. Anyone who possesses a large, cool conservatory, corridor or cold greenhouse may, by planting Acacias in open borders or in large tubs, attain a degree of success that can never be hoped for under more restricted cultural conditions. A high temperature is not essential to success; in fact, more satisfactory results are

achieved by growing the plants quite cool; and in frosty weather, except during the flowering season, the temperature in the structure where they are housed may well be allowed to drop to freezing point before fire-heat is applied. When in a cool house with a good circulation of air, the plants are vigorous and the foliage is rich in colour, while there is less chance of thrips and

nealy bug attacking them. When grown in heat, these two pests are sometimes frequent, and seriously affect the health of the plants, for cleanliness is an essential. Specimens that are planted in large tubs or open borders should be placed in moderately sandy soil which is thoroughly well drained, for, though Acacias like a fair quantity of water during the growing season, they are impatient of stagnant moisture, and anything approaching sour soil is often fatal. With plenty of root room and a cool temperature, water is only occasionally required during the winter months, and the man entrusted with their culture should be careful to give water only when the soil is becoming dry.

The culture of large specimens, once the potting, watering and ventilation are mastered, gives little embarrassment, for pruning consists of a good cutting back as soon as the flowers are over, and cultivation for the next few weeks means keeping the structure rather closer than usual and the plants frequently syringed until new growths are formed. About mid-summer those in pots and tubs may be placed out of doors and left there until the end of September.

Rehousing demands a little attention, for, if abundant ventilation is not given night and day for a while and a light syringing over morning and evening for a few weeks, the plants are likely to suffer. The most satisfactory compost for these plants consists of two parts of good fibrous peat, broken up rough, one part of good fibrous loam and about half a part of coarse sand, while potting should be firm. Cuttings of many of the kinds may be rooted during spring and summer. The young plants for the first year may with advantage be grown in a moist intermediate temperature. They should be kept well stopped, to ensure a bushy habit, by laying a good foundation. Flowering must not be encouraged the first year, the great object being to obtain strong examples for succeeding years. Of some sorts very good plants with five or six strong shoots 12 inches to 18 inches long, covered with flowers throughout the greater part of their length, may be obtained in two years from cuttings, the plants being in pots from 5 inches to 6 inches in diameter. A similar soil to that recommended for large plants is desirable, but it must be broken up somewhat finer. Over-potting is a great mistake in growing the Acacias, and it is far better to feed the plants than to use large pots. Weak liquid manure may be given with advantage from the middle of summer until the end of the growing season, after which time an occasional application only is required through the winter.

Good Kinds for Pot Culture are *A. acinacea*, a species with small leaves and fine wiry shoots; *A. armata* and its variety *angustifolia*; *A. cultriformis*, conspicuous by reason of its rich glaucous phyllodes and deep yellow flowers; *A. Drummondii*, with its flowers in short spikes; *A. hastulata*, *A. juniperina*, *A. linifolia*, *A. longifolia* var. *floribunda*, *A. myrtifolia*, *A. obliqua*, *A. platyptera* and *A. verniciflua*. If pillars have to be covered, no better kinds can be found than *A. leprosa*

and *A. riceana*. The main branches should be supported and the remainder allowed to hang loose. If a large structure is available, stronger-growing sorts, such as *A. dealbata*, *A. baileyana* and *A. verticillata*, may be tried with success, but they can only be grown with advantage where abundance of room can be given. The flowering period is spring, but with a little management a succession of bloom may be had from Christmas until the end of May. W. D.

SOME BEAUTIFUL WINTER-FLOWERING SHRUBS.

THE WYCH HAZELS.

ALTHOUGH there are a number of plants which flower naturally in the outdoor garden at mid-

This is known as *H. mollis*, and the accompanying illustration indicates its bushy, spreading habit, and at the same time shows the wealth of brilliant golden-hued blossoms with which the shoots are wreathed. These flowers are composed of long, narrow and very curiously crimped and twisted petals. When first grown it was considered necessary to provide this beautiful shrub with a mixture of light loam and peat, but I believe that the Hon. Vicary Gibbs has cultivated it with considerable success in the stiff clay soil that naturally prevails at Aldenham House, where, several years ago, there was a fine bush some five feet high. So far as our necessarily limited experience goes, it does not seem to matter much what aspect is chosen, but always in planting one should select, if possible, a background of dark-leaved evergreens, such as Hollies or Yews,

A LARGE BUSH OF THE CHINESE WYCH HAZEL, *HAMAMELIS MOLLIS*. THIS FLOWERS DURING JANUARY AND FEBRUARY.

winter, it is exceptional to find them in any but the most extensive private collections. It is true that if these plants were to blossom in the summer, their flowers would scarcely be noticed among the wealth of blossoms that surround us at that time; but coming as they do at this season, when even greenhouse flowers are scarce, it is difficult to understand why they are not more widely known and cultivated. In the Wych Hazel or *Hamamelis* family we have several hardy shrubs of rare winter beauty, the older members of which have been known in a few gardens for quite a long time, but these have been almost eclipsed by the introduction, some twelve years ago, of a new species from China.

and a position that the rays of the sun can reach nearly all day long. This is not advised on account of shelter or warmth, which do not seem necessary, but merely to get the best effect when the shrubs are in flower. To see bushes such as that illustrated kissed by the winter sun and mirrored, as it were, in a sombre background of evergreens is a sight worth going far to see, and one that will not be readily effaced from memory.

Superior as this comparatively new species is to the older ones, the latter are well worth cultivating, as they flower at different periods of the winter. The best known is probably the North American Wych Hazel (*Hamamelis virginica*), which produces its yellow flowers in

autumn, usually about October. As, however, it is in leaf at that time, the blossoms often pass almost unnoticed. The *Mansak* of Japan (*H. arborea*) is a much more valuable shrub, or small tree, flowering as it does in January, immediately after, and occasionally at the same time, as *H. mollis*. It has deep yellow flowers, which are generally so freely borne as to create quite a shimmering cloud of gold in the winter landscape. Closely following *H. arborea* comes *H. japonica*, which has rather paler-coloured flowers and is of a more lowly stature, while its variety *zuccarini* has pale lemon-coloured flowers that appeal more to some tastes than those of deeper hue. Although all the *Wych Hazels* are rather slow-growing, it cannot be said that they are difficult to cultivate, ordinary well-drained garden soil apparently suiting them to perfection. Once established, they look well after themselves, and need little attention beyond a slight thinning of the branches at rare intervals. H.

NEW PLANT.

Cattleya Trianae Queen Elizabeth.—A very beautiful all-white flower, save for the slight shading of canary yellow in the throat. An exceedingly chaste variety, of handsome proportions. Exhibited by J. Gurney Fowler, Esq., Brackenhurst, Pembury, Kent. Award of merit.

This was the only new plant to receive an award from the Royal Horticultural Society on the 2nd inst.

THE EARLY FLOWERING COSMOS.

Those who have only grown the old *Cosmos bipinnatus* know to their cost that, although it will make a noble foliage plant, it seldom produces flowers until quite late in the autumn, when they are quickly ruined by frost. Thanks to the efforts of our leading seedsmen, we now have an early flowering race, listed in most catalogues as early flowering hybrids. These are particularly valuable annuals for cutting, commencing to flower as they do early in July, and continuing until well into October. Their flowers resemble in appearance those of very graceful single Dahlias, and each has a long, graceful, but wiry stem. Each plant makes a graceful bush about three feet high, and the colours embrace rose, crimson and white. Seeds ought to be sown during February, preferably one or two in a 3-inch pot, and the seedlings raised on a gentle hot-bed or in a slightly heated greenhouse. If these are subsequently potted into 5-inch pots, and hardened off in the usual way, they will make excellent plants for putting outdoors the first or second week in June. So far as our experience goes, this early flowering race of *Cosmos* will do well in any reasonably good soil.

GREENHOUSE SWEET-SCENTED FLOWERS.

It is at least questionable if fragrance in flowers is regarded as of so great an importance as it used to be. This is borne out by the fact that among the newer Carnations and Roses, provided they are of large size and good shape, their scent is in many cases looked upon as of minor consideration, though the old-fashioned varieties of both these genera were remarkable for their delicious perfume. Even in the case of the *Heliotrope*, or *Cherry Pie*, some of the varieties with very large

brown outside and yellowish within. The perfume of the flowers of this *Boronia* is very suggestive of Violets, and a few blooms will make their presence manifest in a good-sized structure.

Luculia gratissima, which was so finely shown at a December meeting of the Royal Horticultural Society and illustrated on page 623, issue December 26, 1914, has large *Hydrangea*-like heads of blossoms, very sweetly scented. Apart from bulbous plants (to be referred to presently) which bloom in a greenhouse during the winter are Carnations, some sorts at least, and *Cheiranthus kewensis*, rather a dull purplish-flowered member of the *Wallflower* family, but most deliciously scented.

It will flower throughout the winter. The large double *Wallflowers* will, if sown in June or July, flower quite early in the spring. They are very sweetly scented. Stocks, too, are very useful for greenhouse decoration nearly all the year round. The tall-growing *Beauty of Nice* is excellent for flowering in the winter, while, by varying the time of sowing, members of the different sections may be had in bloom at various times.

Bulbous plants are in many cases sweetly scented, the fragrance of the *Roman Hyacinth* being far more agreeable than that of the larger-flowered forms. The *Freesias* and some of the *Narcissi* are also remarkable for their scent. Of *Lilies* the sweetest is *Lilium longiflorum*, whose long, silvery trumpets may be had practically all the year round. *L. auratum* is almost too overpowering where at all confined, as in a greenhouse. *Tuberoses* must, of course, be included in any selection of bulbous plants with sweet-scented flowers. Good dormant bulbs may be obtained now, and should be potted with little delay. Many other greenhouse plants with sweet-scented blossoms are at their best at different periods of the year. Among them are some of the *Primulas*, the *Arum Lily*, *Rhododendrons* such as *R. Edgeworthii* and *R. fragrantissimum*, *Cytisus racemosus*, *Daturas* or *Brugmansias*, with long, white trumpet-like flowers; the summer-

blooming *Bouvardia Humboldtii corymbiflora*, the fragrance of whose flowers is suggestive of the *Jasmine*; *Gardenias*, at one time very popular as button-hole flowers, but now not much grown; the tawny-coloured *Magnolia fuscata*, the fragrance of whose blossoms suggests *Pineapple drops*; and others.

Of climbing plants, among the most remarkable for their scent are *Jasminum grandiflorum* and *Rhynchospermum jasminoides*, both with white blossoms.

That well-known annual the *Mignonette* is such a universal favourite that its fragrant blossoms are much appreciated in the greenhouse, especially when they are not obtainable out of doors. Seed sown from midsummer onwards will give flowers

CATTELEYA TRIANAЕ QUEEN ELIZABETH, A NEW VARIETY WITH WHITE FLOWERS.

heads of blossoms are less fragrant than those which are more nearly related to the old *Heliotropium peruvianum* itself. This last is much less used for clothing the walls or pillars of a greenhouse than it used to be, though under such conditions, given a temperature of 50° to 60°, it will bloom throughout the winter.

It is at this season that some of the most fragrant flowers are at their best, notably *Daphne indica*, or *odora* as it is sometimes called, and its white variety *alba*. For general purposes the typical purple-flowered form is preferable, as it grows more freely than the white kind. Another greenhouse shrub remarkable for its delicious fragrance is *Boronia megastigma*, of slender, *Heath*-like growth, with small, drooping, bell-shaped flowers,

throughout the dull period of the year, provided the plants are given as much air as possible. *Nicotiana affinis* and some of its hybrid forms remarkable for their fragrance are also valuable for greenhouse decoration. An old-fashioned stove plant that I have not met with for a long time used to be grown for the fragrance of its dark maroon purple blossoms. This is *Tinnea aethiopica*, a member of the Labiate family. It is of a half-shrubby character, and is easily grown in a warm structure.

As companions to the many greenhouse plants with sweet-scented flowers, a few of those with fragrant leaves claim recognition. Chief among them are the Pelargoniums, with their widely dissimilar scents; the Lemon-scented Verbena, which is hardy in some parts of the country; *Humea elegans*, that also possesses the merit of ornamental flowers; the Pineapple Sage (*Salvia rutilans*), Boronias, and different kinds of Eucalyptus, of which the Citron-scented *E. citriodora* is one of the most pleasing.

H. P.

HOW TO INCREASE SUPPLIES OF VEGETABLES.

BY a carefully planned system of intercropping it is possible to grow more crops than usual, and the following notes are intended to assist readers in this direction. The principal crop is the Potato, as this supplies food all the year round, and an area of 6 rods to 10 rods will be required for this crop by an average family. About three-fourths of this area should be devoted to midseason and late crops, and the remainder to early kinds. Most early Potatoes are short-stemmed, and if given a space of at least 2 feet between the rows, green crops, such as Savoy Cabbages and Kale, could be planted between them after the final earthing. If, when the early Potatoes are planted, the rows are marked, a row of quick-growing Radishes, such as French Breakfast, could be sown between the Potatoes. They would be ready for use by the time the Potatoes were showing through the soil. This plan, however, is not recommended for the stronger-growing late kinds, as it leads to overcrowding.

A succession of Peas can be obtained by sowing early, second early, midseason and late varieties. The distance between the rows of Peas should be determined by the height to which each variety is expected to grow. Thus, a 4-foot Pea should be given a distance of 5 feet between the drills. Now the space between the rows can be made use of by first sowing some quick-growing crops, such as Lettuce, Spinach or Radishes. These crops, if sown or planted when the Peas are appearing above the ground, would be ready for use before the Peas are high enough to provide dense shade. Furthermore, this space can be used for planting out other crops that will continue to grow after the Peas are removed in July. Marrows raised under glass could be planted out between the Peas, say, after Spinach, and when the Peas are gathered they would quickly cover the whole of the space. Celery and Leeks, too, can be planted out in trenches either immediately the Peas are removed or even before, provided plenty of space is allowed between the rows of Peas.

Autumn-sown Onions can be followed by green crops for winter use. Spring Cabbage can be followed by Turnips, Lettuce and Spinach.

Coleworts are very useful vegetables to grow, and if these are sown in May they can be transplanted in any plot that becomes vacant by the removal of earlier crops. They often prove useful for succeeding the midseason varieties of Potatoes.

Cauliflowers such as Early London or Early Forcing will provide a supply of nice heads in July and August if raised under glass in February and planted out in April on a warm, rich piece of ground.

The root crops, such as Beet and Parsnip, require the space allotted to them practically the whole season and do not allow for intercropping; but the round Beet, if sown on a warm border in March, will be ready for use in August or possibly earlier. Carrots, however, differ from the other root crop, inasmuch as it is possible to make a succession of sowings from March to September, and so maintain a long supply of roots. The Early Horn type of Carrot is the best for the first sowing in early spring and for sowing from July onwards. The same kinds are useful for sowing in frames in February or March to provide a supply of tender young roots when vegetables are scarce.

These notes are intended merely as a guide to those who are planning their gardens, and no pretence is made of showing a complete scheme of intercropping. Other methods in addition to the above may suggest themselves to readers, but my object will be accomplished if I have persuaded some cultivators to give more attention than usual to the careful planning of their gardens.

A. E. B.

WINTER SPRAYING OF HARDY FRUIT TREES.

THIS operation might be more suitably termed "February spraying of hardy fruit trees," since it is during that month that the bulk of the work is carried out. The initial stages in the unfolding of the buds coincide

with the earlier hatchings of the eggs of such general insect pests as Apple sucker, aphides and red spider, and since this pre-incubatory phase is the most vulnerable period of the egg, there is good reason for deferring winter spraying to as near the eve of bud unfoldment as is consistent with safety. Frequently at this period, moreover, settled fair weather prevails—a most important factor in achieving results of economic worth.

Winter spraying is accepted as a prime essential in successful fruit culture. It is not practised so generally as it should be, amateur growers being particularly lax in this matter. Though in no way a specific for all the ills fruit trees are heir to, it contributes greatly to success in fruit-growing.

Equipment.—A syringe and a bucket or two are all that is needed where a few trees or bushes only are to be done. Where, however, there are tall trees or a plantation of a rood to an acre in extent, a knapsack spraying machine is indispensable. Where this area is exceeded, a wheel spray pump will be an economic necessity. The

preparation of large quantities of the spraying liquid will also necessitate the use of a barrel of 20 gallons to 40 gallons capacity.

Spraying Solutions.—The use of limewash for destroying algæ, moss, lichen and perchance to some extent hibernating insect pests has long been known. Even now many small fruit-growers rely upon it, though improving on their grandfathers' system of washing the tree trunks, in that they now spray the whole tree. The proportions used are 1 gallon of lime to 10 gallons of water. Careful slaking and subsequent rendering into a milk-like solution are necessary. A pound of soft soap, or size is sometimes added to give the wash tenacity.

Lime Sulphur.—In the combination of these two substances we have one of the most effective sprays extant. The general formula is: Quicklime, 10lb.; flowers of sulphur, 20lb.; water, 10 gallons. Prepare by carefully slaking the lime, and while in the dust-like condition intermix with the sulphur. The mixture is then rendered into a paste by a steady addition of water. When the full quantity of water has been added, the solution is boiled for an hour. After settling and straining, an orange red coloured solution should result. This will need testing with a hydrometer to ascertain whether its strength approximates to that suitable for winter spraying, viz., 1.01. Excepting large fruit-growing establishments, it will be most advisable to purchase this wash ready made and placed on the market at standardised strength.

Caustic Soda Washes.—These share with lime sulphur the reputation of being the most efficient of winter washes. Their merit is further enhanced in that they are clean, easy to prepare, and impart no objectionable appearances to the trees treated. The simplest formula is: Caustic soda (98 per cent.), 2lb.; carbonate of potash, 1lb.; and water, 10 gallons. Prepare by dissolving the salts separately and stirring afterwards into the bulk of the water. The Woburn formula is: Iron sulphate, ½lb.; quicklime, ¼lb.; caustic soda, 2lb.; paraffin (best), 5 pints; and water, 10 gallons. Prepare by dissolving the iron sulphate in 9 gallons of water. Render the lime into a milk and strain into the iron sulphate solution. Add paraffin, stirring vigorously, finally adding the caustic soda in powder form. The writer has found this wash very effective against Apple scab and woolly aphis.

Hints on Application.—A pressure of 80lb. to the square inch is most desirable. Wet the whole of the tree, but avoid wasting. In using lime sulphur or other lime washes, it is imperative that all fittings and machine be thoroughly rinsed immediately after the cessation of work. The face and hands must be protected when applying these washes, particularly when using the caustic soda washes.

Cost of Spraying.—This is largely governed by the apparatus used, local rate of wages, and the character of the fruit trees or plantation. Using a knapsack sprayer and paying the operator 6d. an hour, a bush Apple tree 9 feet to 10 feet high and 8 feet to 9 feet in expanse will cost about 1½d., this sum including cost of wash (half a gallon on an average) and labour. An acre of this type of tree planted 12 feet apart each way would require about 150 gallons of wash at a cost of about 10s. 6d., the cost of application also averaging 10s. 6d.

Morpeth.

C. W. MAYHEW.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Strawberries.—When the flower-spikes are developing, the plants will need a warmer temperature. Give them plenty of stimulants till the flowers begin to open. During the flowering stage keep the atmosphere on the dry side and encourage a free circulation of air during fine, congenial weather, but avoid cold draughts. When the fruits have set, reduce them to five or six of the most promising, and secure the trusses to stakes. The temperature of the house may now be raised to 60° or 65°, syringing the plants two or three times a day with lukewarm rain-water. Introduce fresh batches of plants into heat as required.

Cherries in Pots.—Much care is needed in the management of these till the fruits have set. At no time must they be unduly hastened by the use of artificial heat. Water sparingly till the fruits have set, using water which is of about the same temperature as the house. If the trees were repotted in the autumn, no stimulants will be needed till the fruits are swelling. Fumigate the house with a nicotine compound just before the trees commence to flower.

Early Pot Vines.—As soon as the berries are large enough, the bunches must be thinned. Black Hamburg must not be thinned too much, or the bunches will be loose. Foster's Seedling may be more severely dealt with. The Vines will now require very liberal treatment in regard to watering and feeding. It is a wise plan to fill the pots twice when water is needed. The temperature of the house may now be raised to 70° at night, and full advantage must be taken of sun-heat by closing the house early in the afternoon. Encourage a moist atmosphere at all times.

Plants Under Glass.

Carnations.—The young plants which were potted up last month may now be stopped. Continue to pot up cuttings which are sufficiently rooted, and keep them close for a few days till the roots are again active. Malmaisons may now be more liberally treated in regard to watering. Keep the growths secured to neat stakes. If the roof glass needs washing, this must be done, as the plants need all the light possible. Fumigate occasionally to destroy aphids.

Pot Roses.—As the plants approach the flowering stage they will require more water. Stimulants may also be given more liberally. The Rose maggot must be watched for, or it will spoil a great many of the flower-buds as well as disfigure the foliage. The house must be ventilated with due consideration to the outside conditions, or mildew will spread rapidly. This pest should be anticipated by the discriminate use of flowers of sulphur. Roses planted out may be given copious supplies of liquid manure when in active growth. A top-dressing of rich farmyard manure will also be of benefit.

Climbing Plants.—Plants growing over the roof in the conservatory may now have their annual pruning or thinning. Now is the time to give them a thorough cleaning if they are infested with mealy bug. Well wash the glass and woodwork, and remove an inch or 2 inches of the surface soil from the border and replace with fresh material.

The Flower Garden.

Herbaceous Borders.—The work of making new borders or replanting old ones must be persevered in whenever the ground is in suitable condition. Most perennial subjects require a deeply cultivated, well-manured soil in which to thrive. Well-seasoned farmyard manure is perhaps the best for this purpose, but, failing this, well-rotted leaves will do. Soot, too, may be used with good effect.

Michaelmas Daisies.—There are now some very beautiful varieties of these late autumn-flowering subjects, and few plants stand the strain of our typical autumn weather better than these. Unfortunately, their real characteristics are often spoiled by growing the clumps too large. They need reducing every year, leaving no more than six or eight shoots on each plant.

The Rock Garden.—Now that growth is becoming active, a constant watch must be kept for slugs, as there is nothing more disappointing than to have one's choice plants destroyed by these marauders. Vegetables which they are known to eat should be laid about as traps. A ring of fine coal-ashes placed around some of the choicer plants will keep them at bay. The planting of many subjects may be proceeded with now.

The Hardy Fruit Garden.

Preparations for Grafting.—Any varieties which are considered useless may be replaced by grafting, providing the trees are in good health. They may be headed back now in readiness for the operation when the sap is rising in the spring. In the meantime, collect suitable shoots of the varieties required, tie them in bundles with a label attached, and heel them in at the foot of a north wall.

The Kitchen Garden.

Celery.—A sowing may be made now for the earliest supplies. Sow the seeds thinly in shallow boxes, and place them in a house with moderate warmth.

Leeks.—A small sowing of Leeks for early use should be made now. They may be treated as advised for Onions in a previous calendar.

Parsnips.—No time must be lost in sowing this important vegetable as soon as the ground is in suitable condition. Any roots still in the ground may now be dug up and stored in a cool place.

Shallots and Garlic.—These may be planted as soon as the ground is in workable order. Plant them in rows 1 foot apart. The ground should be richly manured and deeply dug.

Seakale.—The whole of the crowns may now be lifted and placed closely together under a north wall. The best roots may now be prepared for planting as soon as the ground is ready. In the meantime, tie up the thongs in bundles of fifty, and cover them with soil to the depth of 4 inches or 5 inches. E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Fruit Under Glass.

Peaches and Nectarines.—The early house will benefit from a fumigation, as fly is always troublesome in the early stages of growth. If there is only a slight attack in one or two places, the use of an insecticide will be sufficient, applied to the parts affected. The syringe must be used freely on bright days, both morning and afternoon, closing the house early to retain as much sun-heat as possible.

Second-Early House.—Trees in this will already be swelling their flower-buds, and should receive a fumigation, which will keep the house free from insect pests until flowering is over. Not much artificial heat will be required during the daytime, unless the weather is very cold. A slight circulation of heat in the pipes at night will be necessary.

Plants Under Glass.

House Scrubbing.—The cleaning of any plant-houses that is not already done should now receive attention. When possible, the interior of glass-houses should be painted about every third year; this not only greatly improves the appearance generally, but is a splendid help in keeping insect life in check. The plants, having been removed during the house scrubbing, should be well sponged to get rid of any filth before returning them to their newly cleaned quarters. Such plants as *Panicum*, *Episcia fulgida*, *Ruellias* and *Selaginellas* should be propagated, to furnish nice young clean plants to replace the exhausted ones which were used to furnish the edges of the plant-house stages.

The Hardy Fruit Garden.

Wall Trees.—Any Plums, Apricots, Cherries and Pears not yet tied or nailed should be dealt with before the buds get too far advanced. Peaches and Nectarines are better left loose for a while longer, as this helps to retard the flowers, which are so often injured by late spring frosts. When the train-

ing of the trees has been completed, the borders in which they are growing should receive attention. Too often the majority of the roots exist under some hard, trodden alley, which rarely, if ever, gets any manure or attention. If possible, top-dress with good fresh loam and well-decayed farmyard manure; then point over lightly with a fork.

Loganberries.—These and the many other hybrid fruits of this type are well worth inclusion in the fruit garden. They add variety to the dessert fruits and make a welcome change among fruits used for preserving. They are all of free growth and easy culture, not being at all particular as to soil. The same treatment as given to Raspberries will suit them, provided they are allowed plenty of room on which to train their long growths.

The Kitchen Garden.

Broad Beans.—Where required early, a sowing may be made in some warm, sheltered border. If the weather and condition of the soil do not permit of this, sow thinly in boxes indoors, this vegetable transplanting quite readily.

Spinach.—As soon as the condition of the ground will allow, make a sowing of this vegetable. If a very early supply is needed, make a sowing indoors. With a temperature of 55° to 60° Spinach should be ready to pick in a month to five weeks' time, and the quality is very superior to Spinach grown outdoors.

Cucumbers.—Seed for the chief summer crop may be sown in a stove or warm pit. Except that the flowers do not require fertilising, the culture is much the same as that of Melons. Being very subject to attacks of red spider, the syringe must be used very freely, especially on the under sides of the foliage. Cucumber plants are of vigorous and rapid growth; therefore it should be seen that they do not starve or waste more time than is necessary in the small seed pots.

Shallots may now be planted when a piece of ground has been prepared for them. Do not plant deeply, and make the lines 15 inches apart. This crop will thrive on much poorer land than is generally prepared for Onions.

Rhubarb.—In many gardens this subject is much neglected, sometimes receiving no attention for several years together. New plantations ought to be made occasionally, and the present is a suitable time to do this. Before planting, trench the ground and treat it with a very liberal dressing of cow-manure. It is not advisable to pull Rhubarb from new plantations during the first season.

The Flower Garden.

Clematises.—Plants of the *Jackmannii* type ought now to receive attention in the matter of pruning. Having prominent buds, the living growths will now be easy to distinguish. After all dead wood has been removed, the previous year's growths should be reduced to about half their length, pruning some hard back so as to encourage young growths, which will keep the lower part of the plants furnished.

Sweet Peas.—It is now generally acknowledged that to get the best results Sweet Peas ought to be sown in pots during October or early in November. Any seeds which were not sown at that time should be got in at once if the plants are to be in flower by the end of June. Where time and room will allow, sow only one seed in a 3½-inch pot. Instead of the usual potsherds, place either large pieces of turf or fairly new leaf-mould in the bottoms of the pots; this will prevent the plants from starving when planting-out time draws near.

Lobelia cardinalis and its varieties should now be divided into moderate-sized pieces and either be potted or boxed up. They should not be subjected to a strong heat. A newly started vinery or Peach-house will suit them until they are fairly started into growth, when they may be removed to cold frames.

Salvia patens.—If it is desired to increase the stock of this very fine blue flower, let the plants be placed in heat so as to produce young growths suitable for making cuttings. When large enough for taking, dibble them into sandy soil in either pots or boxes and plunge in a case with bottom-heat. This *Salvia* is also easy to raise from seed, which should be sown now in heat.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FRUIT GARDEN.

VINE STEMS SPLITTING (A. K. M.).—It is rarely one comes across a case of Vine stems splitting. We have never known this to be caused by hard forcing as suggested. The invariable cause, in our experience, has been the subjecting of the Vines to too much frost in winter, and to too sudden a thaw afterwards. (The splitting may not be evident at the time; not till growth begins.) Such injury must undoubtedly weaken the Vine for the first season, and so affect its power to swell and ripen so good a crop as usual. But afterwards, when the wounds have healed, the Vine need not be permanently injured. The best black late Grape to go with Gros Colman and White Muscat will be Appley Towers or Black Alicante. The former is the better flavoured.

TREES AND SHRUBS.

NAME OF CYPRESS (Yew Tree).—The Cypress described in your letter is doubtless *Cupressus sempervirens* var. *fastigiata*. We do not think that it can be procured in this country, but it is possible that Messrs. Rovelli and Fratelli, nurserymen, Pallanza, Lago Maggiore, Italy, could supply plants. They should be procured in pots, as they are difficult to transplant successfully from the open ground.

MISCELLANEOUS.

PROTECTING PEAS FROM MICE (A. T. S.).—If bulbs and Peas are sprinkled with paraffin before planting or sowing, as the case may be, they are often safe from attacks by mice, although it does not always prevent the mice from sampling them. Some people find that sprinkling a little paraffin over the ground acts as a deterrent. Care must be taken, however, that the paraffin is applied with care. The best way to hollow out a solid log is to bore a number of holes into it with an auger having a 1-inch to 1½-inch bore; then with a mallet and chisel chip away the remaining wood. As it is a rather arduous task, it would be advisable to get an experienced wood worker to do the work. The best preparation to make the bark of Apple trees, &c., distasteful to rabbits or hares is Renardine, manufactured by Messrs. Gilbertson and Page, Hertford.

VARIOUS QUESTIONS (E. P.).—1. Neither the Thuja nor Cypress would look like Yew. The first does not transplant well unless in small examples, and both to some extent resent the continuous shearing essential to keep them within limited bounds of a small hedge. We should prefer Yew, the golden one if the green is objected to. Both endure pruning well. If a plant of quicker growth than this is required, try Chinese Juniper. 2. We do not see the need of planting anything to shut out the Apple trees, and for a few years at least they would be in sight above the hedge referred to in No. 1. If the Apple trees are not an ornament where they stand, they might, if not too large, change places with the Nuts. The Apple trees opposite the Barberry appear out of place, and both, we think, would be better away. 3. If you put a hedge here, how do you propose entering the rock garden? The latter already appears to us in a wrong position at the kitchen garden end of the ground, and

if you arrange a hedge in front of it, the rock garden will fall between this and the brick wall. If the above plants were removed, a raised shrub border might be formed for screening purposes, planting it with *Berberis Darwinii*, *Spiræas* and *Weigelas*. 4. We cannot answer this satisfactorily. Few shrubs do well under trees, and success would depend much on their nature and the amount of shade they cast. 5. We think the Ivy the better ornament in the circumstances. If shrubs are employed at either end, they should be of Winter and Portuguese Heaths, *Skimmias*, and *Berberis Wilsonæ* (in full sun), with *Forsythias* at the back. 6. The rough grass might be trenched in and the place planted with hardy Heaths. With these could be associated a few Japanese Lilies of the speciosum class. 7. For destroying ordinary earthworms in pot plants, mix a strong dose of mustard and water in a pail and stand the plants in it for a few seconds. This or lime-water is usually effectual for the others named. The keeping of Nuts in the way you describe is well known to, and frequently adopted by, country folk, whose primitive methods often surpass those of the modern type. Green fly frequently infests bulbs long kept in cellar or warehouse quite away from other forms of vegetable life, and if only a solitary female insect existed on a bulb in August, it might easily account for the conditions you describe. The best advice we can give you in respect to the rock garden and its surroundings is that you confer with an expert on the spot. It is not possible accurately to advise from the sketch submitted, and the arrangement appears at present somewhat complicated.

NAME OF FRUIT.—W. F. M. C.—The variety is Pearn's Pippin, rather out of character. This may be caused by the situation or position of the tree, or by the stock on which it is worked.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

WE are pleased to be able to record an appreciable increase both in volume and variety at the meeting held on the 2nd inst. as compared with that of the last meeting. Several exhibitors put in an appearance for the first time this year, while fruit and flowers were thoroughly representative in all departments. To demonstrate late-keeping varieties of fruit, Messrs. Cannell staged some seventy dishes of dessert and culinary Apples of superb quality. Mrs. Denison sent about half that number of Potatoes, also a very good sample. The fine bank of forced shrubs from Southgate, opposite the entrance, attracted everyone, while Messrs. Sutton's Primulas and Cyclamen were one of the features of a good meeting. Carnations, alpine and Orchids were freely shown, and contributed much to an interesting display. The show was visited by a goodly throng during the afternoon. Only one novelty received recognition.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. W. Bates, E. Beckett, A. Grubb, A. R. Allan, G. Kelf, Horace J. Wright, J. Davis, J. E. Weston, A. Bullock, G. Reynolds, P. D. Tuckett, E. A. Bunyard, W. H. Rivers, Owen Thomas and W. Poupart.

Messrs. H. Cannell and Sons, Eynsford, Kent, staged a magnificent collection of some seventy dishes of Apples and Pears, the former in both dessert and culinary sorts, with the express object of demonstrating their late-keeping qualities. Not only was the object attained; the whole of the varieties were in as high excellence as might have been expected in October, and as an exhibit of high-class fruits it would be difficult to equal, much less excel. Wedded to excellent quality was the educational value of the display. Of dessert sorts we noted Edward VII., Belle de Boskoop, Belle de Pontoise, Baumann's Red Reinette, Barnack Beauty, Allington Pippin, Winter Peach, Calville Malingre and Newtown Pippin. Of culinary kinds we considered Annie Elizabeth, Smart's Prince Arthur (a splendid sample, and not a bad eating sort), Wellington, Lane's Prince Albert, Bramley's Seedling, Newton Wonder, Reinette du Canada, Norfolk and Striped Beaufin to be among the finer dishes, though all were of admirable quality and finish. Some good dishes of Pears were on view, that of Uvedale's St. Germain of exceptional colour also. A silver-gilt Knightian medal was deservedly awarded.

Grape Fruits were shown by Sir Albert Rollet, St. Anne's Hill, Chertsey, a growing plant nearly eight feet high bearing several handsome fruits.

Mr. Will Taylor, Hampton, Middlesex, displayed an excellent collection of well-kept Apples and Pears, some forty dishes, chiefly of Apples, being staged. Quite a large number of varieties exhibited high coloration, a not infrequent occurrence with varieties grown upon the light, well-drained loam of the district named. Some of the more prominent dishes were Annie Elizabeth, Newton Wonder, Gascoigne's Scarlet, Cox's Orange Pippin, Blenheim Orange Pippin, Ribston Pippin, Bismarck (particularly good and well coloured), Beauty of Kent (of quite remarkable colour), Norfolk Beaufin, Claygate Pearmain, Wellington and Pince's Golden Pippin, the latter an ideal dish. Pear Bergamotte Esperen was also very fine. Silver Knightian medal.

Mrs. E. H. Denison, Little Gaddesden, Herts (gardener, Mr. A. G. Gentle), exhibited some three dozen dishes of Potatoes, for which a silver Knightian medal was awarded. The whole of them were in excellent condition, though we considered that Great Scot, Abundance, Epicure, Schoolmaster, Mr. Bresse, Carter's Emperor, The Factor, King

Edward (a very fine sample) and Ringleader were of outstanding merit. The exhibit attracted considerable attention.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Harry J. Veitch, and Messrs. J. O'Brien, de B. Crawshaw, W. Bolton, S. W. Flory, W. H. White, A. Dye, W. P. Bound, J. E. Shill, W. H. Hatcher, J. Cypher, W. Cobb, T. Armstrong, F. J. Hanbury, Pantia Ralli, Stuart H. Low, Gurney Wilson, J. Charlesworth, C. H. Curtis and R. A. Rolfe.

Orchid groups were displayed on a more extensive scale, and many beautiful kinds were on view. In *Odontoglossum amandens* variety Queen of Spain (*O. wilckeanum* × *O. Rolfeæ*), Pantia Ralli, Esq., Ashted Park, Surrey, had a very handsome novelty, the greater leaning perhaps being to the first-named parent. The ground colour of the sepals and petals is soft yellow, so heavily barred and blotched with chocolate and crimson as to be in the nature of veins. A very striking flower.

Messrs. J. and A. McBean, Cooksbridge, received a silver Banksian medal for a choice lot, which included the blood-crimson *Odontiodas Doris* and *Cooksonia*, *Lælia anceps schröderiana*, L. a. Sanderi (both white-flowered), an interesting variety of *Cypripediums*, together with *Cymbidium Alexanderi* (rosy coloured) and *C. Schlegelii* (whose lilac-coloured sepals and petals are freckled and spotted with crimson).

Messrs. Stuart Low and Co., Jarvisbrook, Crowborough, had the rich orange-coloured *Lælio-Cattleya Doris*, *Lælia anceps Bull's White* (very pure and good), *Odontoglossum Vuylstekeæ vivicans* (a strange commingling of bronze and yellow), *O. Harry-crispum* (very dark form), with *Brassocattleyas* and others. Silver Banksian medal.

Messrs. Cypher and Sons, Cheltenham, staged a handsome lot of *Cypripediums*, of which *C. Euryades splendens*, *C. Helena Westonbirt* variety and *C. aureum virginale* (the latter with a magnificent white dorsal petal) were the chief. *Lælia anceps Hillii* (very fine white), *Cymbidium* in variety and the curious and rare *Masdevallia schröderiana* were also noted in a group characterised by much freshness. Silver Banksian medal.

Messrs. Armstrong and Brown, Tunbridge Wells, were the recipients of a silver Flora medal for a handsome group, in which the outstanding feature was some fifty well-flowered plants of *Cattleya alba* Maggie Raphael, the white-petalled, crimson-lipped flowers very handsome. *Miltonia St. André* (white, with crimson base), *Cypripedium Helen II.* variety Fascinator (rosy colour), *C. Venus Orchidhurst* variety, *Brassocattleya Cliftonii albens* variety, *Masdevallia courtauldiana* (a rather rare species with rosy-coloured flowers), *M. schröderiana*, a variety of *Odontoglossum crispum illustrissimum* crosses, and the violet and crimson coloured *O. thomsonianum* (whose forked, extended racemes promise a considerable profusion of flowers) were others shown.

Messrs. Charlesworth and Co., Hayward's Heath, also displayed a most interesting group—*Brassocattleya Joan* (of rosy pink hue), *Odontioda Wilsonii* (rosy purple, flecked with white), a magnificent raceme of the white-flowered *Odontoglossum armainvillieriensis*, *O. Doris* (dark chocolate), a specimen of *Cymbidium insigne* bearing eight racemes of flowers, the very striking *Sophracattleya Saxa* (of camellia red shade), with *Lælia anceps Stella* and *Lælio-Cattleya Felicia*. Silver Flora medal.

Messrs. Sander and Sons, St. Albans, also had an interesting variety, among which we noted the beautiful *Cattleya Empress of India*, *Brassocattleya sulphurea amabilis*, *Odontoglossum amandum* variety *Grandesse* (creamy yellow with crimson bars), *Cymbidium gottianum* and the quaint *Epidendrum polybulbon alba* (of which one or two pans were shown). The whole plant is not more than two inches high, the narrow sepals and petals coloured yellow, and pure white lip. A very handsome *Cypripedium* was labelled "Moonbeam × *villosum aureum*." Silver Banksian medal.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. W. A. Bilney, F. W. Harvey, B. Crisp, R. Hooper Pearson, E. A. Bowles, W. J. Bean, J. Green, G. Reuthe, G. Harrow, J. F. McLeod, J. W. Moorman, C. R. Fielder, W. Howe, T. Stevenson, J. Hudson, J. Jennings, W. Bain, C. Dixon, J. Dickson, A. Turner, C. E. Shea, C. E. Pearson, W. P. Thomson, E. H. Jenkins and G. Paul.

Messrs. Barr and Sons, Covent Garden, W.C., arranged a very beautiful lot of early flowering plants, of which *Snowdrops*, *Gaultheria procumbens*, the early hardy *Cyclamen*, hardy Heaths, *Eranthis cilicicus*, *Narcissus minimus*, *N. Bulbocodium monophyllum* (very chaste and beautiful), *Crocuses* in many kinds, *Lenten Roses*, *Adonis amurensis* and *Iris stylosa* were among the more choice. *Freesias*, in pots, were also charmingly displayed, and fragrant withal. Bronze Flora medal.

Messrs. Stuart Low and Co., Enfield, Middlesex, displayed *Cyclamen*, *Carnations*, *Camellias*, *Acacias* and other greenhouse flowers. The *Cyclamen* were very beautiful and in great variety. Of the *Carnations*, of which a large group was shown, *Champion* (scarlet), *Princess Dagmar* (crimson), *Lady Fuller* (salmon), Mrs. C. F. Raphael (rose scarlet) and *Gorgeous* (corise) were among the more important. Bronze Flora medal.

Messrs. R. F. Felton and Sons, Hanover Square, again showed the red-fruited *Solanum ciliatum*, a plant of great beauty and ornament, to which we have previously referred. *Lilacs*, *Gelder Rose* and *Eucalyptus globulus* were also well displayed, with *Ruscus racemosus*, *Pittosporums* of sorts and *Olearia Forsteri* as garniture.

Messrs. W. Wells, Limited, Merstham, showed *Carnations* *Pink Sensation*, *Aviator* (scarlet), *Red Benora*, Mrs. G. Lloyd Wigg (white), *Laura Webber* (pink) and *Good Cheer* (pink), a set of novelties for distribution this year.

Mr. Clarence Elliott, Stevenage, displayed an exhibit of alpine, in which an extensive colony of *Saxifraga burseriana* was a chief feature. *Crocus* species, *Gentiana acaulis* and the early *Cyclamen* were shown with rock shrubs.

Messrs. H. B. May and Sons, Edmonton, displayed groups of *Cyclamen latifolium*, *Primula obconica*, *Calla alocasiifolia*, an evergreen species of dwarf habit, with *Cinerarias*, *Azalea Deutsche Perle* and other plants. The *Cyclamen*, in salmon, white and crimson, were very good. Silver Flora medal.

Messrs. Herbert Chapman, Limited, Rye, had well-flowered pans of *Cyclamen ibericum*, together with vases of hybrid *Freerias* and hybrid *Narcissi* in variety. The rather conspicuous red-cupped fungus, *Peziza coccinea*, was also shown in capital form.

Mr. James Box, Hayward's Heath, had a delightful lot of *Saxifraga burseriana*, *Cyclamen Coum*, *Erica mediterranea hybrida*, *Hepaticas* in variety, *Parochetus communis*, early *Iris* in variety and *Primula malacoides*. *Marrubium sericeum* and well-flowered examples of *Hamamelis* were also on view. Bronze Banksian medal.

Messrs. J. Piper and Sons, Bayswater and Barnes, showed alpine and shrubs. *Cyclamen* were very charming, also the white-flowered *Saxifraga burseriana*. The variety of *Saxifragas* was very charming; the shrubs were most interesting. But where was the need for the discordant purple background? Bronze Banksian medal.

Miss C. M. Dixon, Elmercroft Nurseries, Edenbridge, Kent, displayed *Primula malacoides*, *Hyacinth Lord Balfour* (red mauve), *Tulips* and *Primula obconica* in distinct forms, the colour shades blending in a very charming manner; an object-lesson in tasteful arrangement.

The Misses Hopkins, Shepperton, showed single and double *Primroses*, *Hepaticas*, early *Cyclamen* and other hardy flowers.

Messrs. R. and G. Cuthbert, Southgate, had a lovely group of forced shrubs springing from a groundwork of Ferns. *Magnolias*, *Lilacs*, *Prunus*, *Pyrus atrosanguinea*, *Azalea mollis* in variety, *Forsythia* and other plants were delightfully arranged. We believe this to be one of the finest groups ever staged at this early season. Silver-gilt Flora medal.

Messrs. Waterer, Sons and Crisp, Bagshot and Twyford, displayed *Iris alata*, hardy *Heaths*, early *Cyclamen*, *Snowdrops*, *Crocuses* and a considerable variety of *Saxifragas* on rockwork. The dainty *Sisyrinchium grandiflorum* was also on view. Silver Banksian medal.

Messrs. G. and A. Clark, Limited, Dover, had a good strain of *Polyanthuses* with flowers of large size. Many well-flowered examples of *Daphne Mezereum alba* were also shown.

Messrs. Sutton and Sons, Reading, had very fine basket groups of *Cyclamen* and *Primulas*, a considerable table space being occupied. Of *Primulas*, *Reading Blue*, *Double White* and *Prince of Wales* (red) were the chief. The *Cyclamen*, represented by increased numbers, also afforded the greater display by reason of the mass of flowers 8 inches or so above the handsome leaves. In this way we saw *Giant Crimson*, *Superb Fringed*, *Rose Pink*, *Salmon Scarlet*, *Giant White*, *Salmon Pink* and *Sutton's Fringed Pink Pearl*, the last of the "Butterfly" class, of handsome proportions, also of delightful colour. A capital exhibit in every way. Silver Flora medal.

Messrs. Wills and Segar, South Kensington, arranged a table of *Orange trees* in fruit, together with *Azaleas*, *Cinerarias* and *Cyclamen* in fine flower. The plants were in ample groups, one of *Giant White Cyclamen* being particularly pure and well grown. Silver Flora medal.

Mr. G. Reuthe, Keston, Kent, had delightful pots of *Snowdrops*, such lovely winter *Crocuses* as *Imperati*, *Sieberi* (mauve) and the golden yellow flowered *Korolkowii*; double blue *Hepatica*, *Cyclamen Atkinsii purpureum* (a very charming plant), *Erica codonodes*, *Eranthis cilicicus*, and a great variety of *Saxifragas* in an exhibit of alpine and shrubs. Among the latter, *Berberis Bealii*, yellow flowered and charmingly fragrant, was noted. Bronze Flora medal.

Messrs. J. Cheal and Son, Crawley, displayed alpine and shrubs in conjunction with rockwork, employing groups of *Iris reticulata*, *Primula denticulata*, *Anchusa myosotidifolia*, *Saxifragas*, *Veronica Bidwellii* and other plants. *Rhododendron Jacksonii* (rosy pink) was in full bloom, the unforced plants having been lifted from the open in the developing bud stage a week earlier. *Pyra-cantha angustifolia*, a well-armed species, was full of its orange-coloured fruits. It is highly ornamental.

Messrs. W. Cutbush and Sons, Highgate, N., displayed many interesting and beautiful things, particularly *Carnations* and alpine. Of the former, Mrs. L. D. Fullerton (fancy), *Lady Ingestre* (pink), *Lady Coventry* (a scarlet of Malmaison proportions), *Carola*, *Sunstar* (yellow) and *White Swan* were the best. A nicely flowered plant of *Camellia reticulata* was on view. In the alpine section a group of two or three dozen *Iris sind-pers* was in the nature of an "eye-opener," and was greatly admired. *I. reticulata Krelagii*, *Hepaticas*, *Daphne Dauphinii*, *Christmas Roses* and *Saxifraga burseriana major* were also finely represented. Silver Banksian medal.

The St. George's Nursery, Harlington, showed three fine basket groups of *Cyclamen* Mrs. L. M. Graves (scarlet), *Queen Mary* (pink) and St. George (salmon, with handsome marbled foliage, which alone was a great feature. It is a most striking variety).

Mr. Amos Perry, Enfield, again showed a table of hardy evergreen Ferns, comprising leading varieties of the tasseled *Hart's-tongue* (*Scolopendrium*), *Polypodium cambricum* and the more densely plumose forms of *Polystichum*. Each was well represented. Silver Flora medal.

Mr. L. R. Russell, Richmond, was awarded a silver Banksian medal for a collection of fruiting and other shrubs, such as *Skimmia*, *Aucuba*, *Garrya*, *Hamamelis*, forced *Wistaria* and *Prunus triloba*.

Messrs. Allwood Brothers, Hayward's Heath, again showed *Carnations* finely, including *Salmon Enchantress*, *Rosette* (cerise), *Terrific* (pink, of the Malmaison class), *Gorgeous* (cerise) and *Philadelphica* (a pleasing cerise pink with good lighting-up qualities). Mary Allwood was very good. Bronze Flora medal.

The Guildford Hardy Plant Nursery sent a variety of alpine and shrubs, the groups of *Saxifraga burseriana major*, *Veronica pimeloides*, *Muscari azureum*, *Senecio Grayii* and *Daphne floniana* being among the more pleasing items.

NATIONAL CHRYSANTHEMUM SOCIETY.

ANNUAL MEETING.

THE annual meeting of this society was held on the 1st inst. at Carr's Restaurant, Strand. In the absence of Sir Albert Rolitt, who was prevented from presiding by indisposition, Mr. Thomas Bevan took the chair. The adoption of the report and accounts for the past year was formally moved by the chairman, and supported by Mr. E. F. Hawes, who specially alluded to the arrangements made by the National Chrysanthemum Society to hold its 1915 show at the Royal Horticultural Hall, Westminster. He hoped every member would do his utmost to make the show in a new place a success. The election of officers then took place, with the following results: Sir Albert Rolitt, president; Mr. John Green, treasurer; Mr. Thomas Bevan, chairman of committee; Mr. E. F. Hawes, vice-chairman; Mr. Harman Payne, foreign secretary; Mr. R. A. Witty, general secretary; and Messrs. Stevens and W. Walker as auditors. As one-third of the executive committee retire annually, the vacant places have to be filled. The following gentlemen were therefore elected: Messrs. Caseton, Emberson, Ingamells, McKerchar, Noyce, Riding, Runciman, Searle, Springthorpe, Toms, W. Wells, Horace Wright and Faulkner.

A letter was read from Mr. J. W. Moorman resigning his place on the various committees. The resignation was accepted with regret, and many members spoke of the excellent work done by Mr. Moorman during his connection with the society and of his personal merit. Advancing years are the only reason for this gentleman's retirement.

An expression of sympathy was directed to be forwarded to those French Chrysanthemum societies whose members had fallen in the war, been wounded or taken prisoners, some of whom were personally known to the members of the National Chrysanthemum Society.

Mr. Witty referred to the proposal to extend the educational work of the society, and said that in addition to conferences it was intended to inaugurate a series of lectures dealing with various aspects of the Chrysanthemum, cultural and otherwise. It was announced that Mr. Harman Payne would be one of the first to give a paper, the subject being "The Chrysanthemum from a Poetic, Mythical and Romantic Point of View." The series will begin in the spring, and members are cordially invited.

The election of new members brought the meeting to a close, and after a vote of thanks to the chairman the members dispersed after a pleasant evening's work.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

THE first meeting of the present session took place on January 27, and a good number of members were present to hear a lecture on "Some Recent Researches on Plant Nutrition," by Mr. Alfred Machen. The lecturer, a colleague of Professor Bottomley of King's College, London, was listened to with rapt attention while he detailed the experiments made on the action of bacteria on peat, and how it can be converted into most valuable nitrogenous and phosphatic manure. The result of this action gives a black powder, which will shortly be introduced to the horticultural and agricultural world under the name of "Heemogen." A large number of lantern slides (shown by Mr. Coleby) were exhibited illustrating the lecturer's remarks and proving most conclusively that the manure is a real plant food, for the plants to which it had been applied in very small doses were models of what they should be. The Curator of Kew Gardens and many head-gardeners had made extensive trials of the material during the past twelve months, and were convinced of its great utility. A good discussion followed and many questions were asked, which the lecturer answered. A hearty vote of thanks was accorded Mr. Machen, and he briefly replied. Mr. R. Doe, head-gardener to Sir Charles Henry, Bart, M.P., at Parkwood, exhibited a splendid collection of Apples and Pears, with plants of *Begonia Gloire de Lorraine*, *Primula malacoides* and *Cyclamen* interspersed between the dishes; and Messrs. Waterer, Sons and Crisp, Limited, staged an interesting group of hardy plants suitable for rockeries. Both exhibitors were thanked for their displays.

BOURNEMOUTH HORTICULTURAL SOCIETY.

ANNUAL MEETING.

THERE was a good attendance of subscribers at the annual meeting held on January 29. The annual report showed a nice balance in hand after a substantial sum had been given as a donation to the Mayor's War Fund. All the three shows—spring, summer and autumn—proved a success from every point of view. Especially fine were the Chrysanthemums and fruit at the autumn show. The members of this society and the townspeople generally very much appreciated the visit of the deputation, con-

sisting of Sir Harry J. Veitch, the Rev. W. Wilks and Mr. S. T. Wright, from the Royal Horticultural Society. The following awards were made, namely: Three silver cups, three silver-gilt Banksian medals, three silver-gilt Flora medals, two silver Knightian medals and three silver Banksian medals. All the officers were re-elected, and will make every effort to carry on the good work of the society successfully as in the past.

HIGHCLIFFE GARDENERS' ASSOCIATION.

MR. C. J. GLEED, staff teacher, Hampshire County Council, gave a very instructive lecture on "Fungoid Pests" on Monday, February 1. Mr. Murray, Sopley Park Gardens, occupied the chair, and there was a good attendance of members. The lecturer drew attention to the harm resulting from overfeeding crops with nitrogenous manures, which caused a too sappy growth and a predisposition of such to attack by fungoid pests. He referred to silver-leaf in Peaches, Nectarines, Plums and other kinds of plants, and said the disease could be spread from tree to tree by various means, pruning, &c.; also, that where the wood was dead the fruit spores developed. Canker, said the lecturer, was caused by a wound parasite. Varieties with thin rinds were the most subject to canker, but even these were not so liable when grown on a strong Paradise stock. He described American mildew, how it could be detected at the base of the spines near the ends of the shoots on Gooseberry bushes, and strongly recommended cultivators who found it on their plants to carefully cut off such shoots, put them in a box, and forthwith burn both box and affected shoots. In regard to the use of sulphur, Mr. Gleed said the ordinary flowers of sulphur, owing to the smoothness of the particles, was not as efficacious as the black, coarser-grained sulphur. Potatoes should be sprayed with Bordeaux mixture at least twice—first at the end of June if close, moist weather came, then again three weeks after—and, if necessary, the third time about the middle of August. Much more valuable information was given, and both the lecturer and chairman received cordial votes of thanks.

CHELMSFORD AND DISTRICT GARDENERS' ASSOCIATION.

THE eighth meeting of the winter session was held in the East Anglian Institute of Agriculture on Friday, the 29th ult. The president, Mr. E. H. Christy, occupied the chair, and a good number of members were present. Mr. F. A. Waumsley gave a most interesting lecture on "School Gardening." The lecturer, in the course of his remarks, pointed out the following details: Gardening had been taken up by a number of schools, where practical instruction was given. It was not a compulsory subject, and the number of children who had taken it up was considered satisfactory. The subject had been taken up by 2,984 schools, by 51,724 boys and 2,877 girls. Staffordshire stood first among the English counties, Essex taking the fourth place. The effect of such instruction was that it gave the boys a liking for manual work; they took a pride in their own plot, it brought out latent qualities, forethought, taught them to persevere through failure, and was a true education. The school garden contained a demonstration plot, fruit plot and flower plot. In one school the lecturer had seen a weed plot; this was a good idea, as it was as well to know your enemy by sight. Several other points were touched on by the lecturer, all of which opened the field for a good discussion which followed the lecture. At the conclusion of the meeting a hearty vote of thanks was accorded Mr. Waumsley for his lecture.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE monthly meeting of the Scottish Horticultural Association was held in their hall, 5, St. Andrew Square, Edinburgh, on the evening of February 2. There was an excellent attendance to hear the inaugural address of the new president, Mr. William G. Pirie, gardener to C. W. Cowan, Esq., Dalhousie Castle. Mr. David King, Osborne Nurseries, the retiring president, whose term of office has been a most successful one, presided, and introduced Mr. Pirie, who was received with hearty applause. The subject of his address was "Present-day Problems." Mr. Pirie took a wider field than ordinary horticulture, although the subjects dealt with were cognate to gardening. The address was marked by practical knowledge and keen observation, and was heartily received. Among the questions referred to in detail was that of the cultivation of Sugar Beet, which Mr. Pirie considered could be as successfully cultivated in many parts of England and Ireland as on the Continent. The lecturer advocated active assistance on the part of the railway companies, and expressed the opinion that if Beet cultivation were fostered by the railways by their giving special facilities, the industry would become established in this country. Another question of importance at the present time—that of small holdings—also received due consideration in its effect on market gardening. A pertinent point was made of the attitude of the Scottish Board of Agriculture in apparently proposing to parcel out land for the cultivation of vegetables at rents approaching those fixed for agricultural purposes. This, as Mr. Pirie showed, would be unfair to those holding market gardens at high rents, unless these could be made subject to a Land Court. Another "present-day problem" ably dealt with by the lecturer was that of afforestation, especially as it affected the supply of pit props, which had been largely checked by the war. Other items in keeping with the title of the paper were ably discussed, and Mr. Pirie was warmly thanked for an excellent lecture, which augurs well for his success in the chair during the session.

THE GARDEN.

No. 2257.—VOL. LXXIX.

FEBRUARY 20, 1915.

NOTES OF THE WEEK.

The Cornwall Daffodil Show.—After the Rev. J. Jacob's "Daffodil Notes" (page 88) had been sent to press he informed us that the Cornwall Daffodil Show has been abandoned for this year.

Captain Louis de Vilmorin in the Fighting Line.—The following extract from the French Official Journal of the 1st inst. will, we think, be of interest to horticulturists in this country:

"The 8th Section of machine gun cars under command of reserve Captain Louis de Vilmorin volunteered to operate on the first fighting line a battery of 80mm. mountain guns, and contributed very effectively to check the defence of a village by the Germans in supporting by night and day the forward movement of the infantry."

Tulips for Forcing.—Mr. R. P. Brotherston, the well-known Scottish gardener, sends us the following note: "The best forcing Tulip I have ever grown is Proserpine, which with no trouble commences to flower in the middle of December, and at Christmas there is always a good supply of plants and bloom. This year Fred Moore has been very satisfactory as an extra early variety. It is in the way of Prince of Austria and Thomas Moore, and a lovely flower. Of Daffodils I have had a large quantity of Seagull of my own growing, yielding lots of flower. The Flowering White Currant, cut and brought out in a stove, has been in use for decorating since early in the year. It is well worth growing for this purpose alone. The other forms do not force so readily."

Shirley Poppies with Blue Flowers.—

Last spring we were rather startled to receive from Messrs. J. Carter and Co. a packet of seeds labelled "Blue Shades of Shirley Poppy." These, the firm were careful to explain, had been raised by Mr. Luther Burbank, and were in sealed packets sent direct from the United States of America, so that Messrs. Carter could accept no responsibility for the colour description. When the plants that were raised commenced to flower, we were not greatly

impressed with the colour of the blossoms; but later, some gave very charming flowers, varying from smoke grey to slaty blue. These were exceedingly pretty for house decoration during daylight, but were not seen to advantage when artificial illumination was resorted to. As will be seen by the accompanying illustration, the flowers are the same in form and poise as those of ordinary colours.

A Beautiful Early Spring Crocus.—In *Crocus tommasinianus* we have one of the best of the early spring Crocuses. The outer petals are of a silvery dove tone, while the inner segments are of a delicate mauve blue, making it very attractive. It is, although small, stout in its habit, and stands the weather of an early period of the year with little distress. Even when not

by Mr. F. C. Miles on albinism in Maize being of special interest to horticulturists. The journal is edited by Professor W. Bateson, M.A., Director of the John Innes Horticultural Institution, and published by the Cambridge University Press, Fetter Lane, London, E.C.

Two Dwarf Uncommon Shrubs.—The genus *Sarcococca* is not very well known and seldom seen

in gardens, yet it contains several interesting little shrubs that are suitable for the rock garden. The two we have in mind are of recent introduction from China, and although in neither case are the flowers very conspicuous, they are interesting and very fragrant. As they open at this time of the year, they are worthy of a place. One is *Sarcococca humilis*, a neat little shrub from 1 foot to 1½ feet high, with rich green, glossy leaves, bearing racemes of whitish flowers, with clusters of conspicuous red stamens. The other is *S. ruscifolia*, a stronger grower, but very pleasing with its neat habit and dark polished leaves and clusters of white flowers. The flowers of *Sarcococca* are unisexual, but the two sexes are produced on the same axillary raceme, the females being at the base. The *Sarcococcas* belong to the Spurge family and are closely allied to the Box.

Journal of the Kew Guild.—This journal for 1915 is a particularly interesting one, containing as it does several articles and notes bearing directly upon the war. Thus the frontispiece is a portrait of M. Louis Gentil, an Old Kewite who is Curator of the Brussels Botanic Gardens and editor of the *Tribune Horticole*. The article by M. Val Bouckennooghe, entitled "The Bombardment of Ypres," places vividly before us the awful trials that horticulturists and other civilians have been subjected to in the bombardment of that and other Belgian towns. M. Bouckennooghe, who is also an Old Kewite, has been in business as a nurseryman at Ypres for some years, and is now a guest of friends in this country. Other articles deal with the work of Kew

SOME OF THE BLUE-FLOWERED SHIRLEY POPPIES.
THESE ARE VERY USEFUL FOR CUTTING

open to the sun it is pretty with its peculiar, attractive feathering showing on the flower.

Physiology of Fertilisation.—Those who are interested in the physiology of fertilisation in plants and animals will find the current issue of the *Journal of Genetics* particularly useful. The whole of the number is devoted to numerous experiments that have been conducted, those

men in all parts of the world, and form a striking testimony to the activity of horticulture in remote corners of the globe that owes its success to Kew. The editor of the journal and secretary of the Guild is our sub-editor, Mr. H. Cowley, who, as our readers are probably aware, is serving with the British Army in France. The work of editing the present issue has been undertaken by Mr. A. Osborn.

HOME-GROWN VEGETABLES AND OUR FOOD SUPPLY.

We continue to receive a number of letters on this important subject. Dr. Lillias Hamilton very properly indicates the necessity of growing those kinds of vegetables that are the most valuable from a food standpoint, and her suggestion of co-operative piggeries in connection with allotments deserves earnest consideration from local horticultural societies. The letter signed "F.R.H.S." is from one of the best-known men in the horticultural world, and we commend his suggestion regarding Wisley to the Council of the Royal Horticultural Society.

I THINK the advice given in your article of February 6 is excellent, being both timely and useful. The Royal Horticultural Society of Ireland have appointed a committee to form an Irish branch of the Vegetable Products Committee, established to supply garden produce to the North Sea Fleet. BESSBOROUGH.

I THINK I have as much sympathy for the wounded and suffering as any of your readers, but I do not see my way to throw up my hat in approval of the scheme you advocate for the supply of vegetables to our hospitals and Fleet. You must never forget that market gardening is a great industry, and if supplies of vegetables are required for our Fleet, let them be ordered through the proper channels, just as bread or beef or cheese is ordered. Why is it always the horticulturist who is expected to give things free? Why do we never see proposals for grocers to set aside six cheeses every week, or for farmers to give a sheep every week, or for bakers to give a batch of loaves every week, free, to feed our sailors? When we come to the hospitals it is rather different; but why free vegetables any more than free drugs or free milk and eggs? Again, I say the interests of the market gardeners are to be considered. By far the best thing to do is to encourage the increased growth of Potatoes and vegetables among the people themselves for their own and their children's food, and if there are surpluses, let them by all means be given away. Let all big people with large gardens and vineries run them as usual and give their produce to the hospitals, as is being done at present by some.

W. CUTHBERTSON.

[We think Mr. Cuthbertson has rather misunderstood the purport of our article. The idea is not so much the supplying of vegetables to our Navy or Army as to induce amateurs and cottagers to grow all the food they can during the coming season. Any surplus could be put to good use by a local society undertaking to collect and despatch it to hospitals, nursing homes or other institutions where wounded soldiers or sailors are being cared for. Mr. Cuthbertson must surely have heard of "pound days" at hospitals, where a pound of some kind of grocery is given for the inmates.—Ed.]

THE article on "Home-grown Vegetables and Our Food Supply," in your issue of February 6, raises an important question, and suggests, I think, a valuable policy. One or two special considerations occur to me.

In the first place, as regards the choice of vegetables to be put in the ground, it is to be hoped that the responsible committees will select, according to locality, such as are most nourishing and such as are easily stored. Both these considerations point to root crops, especially Potatoes, which are imported in such enormous quantities from Germany every year. There does not appear to be any shortage of green vegetables

at present, and the pressure on our supplies is likely to increase towards the autumn and during the winter months. If every garden holder in the kingdom put down even the smallest quantity of Potatoes, Carrots, Beets and other root crops, and also Onions, the result in six or eight months' time should be a considerable and valuable increase of foodstuffs for the nation.

Secondly, it seems to me that not only can the horticultural societies be utilised, as you suggest, as local advisory bodies and distributing agents—as local co-operative centres, in fact—but that these societies already form the nucleus of a national system of co-operation. Instead of each locality acting independently, the system of intercommunication among the different districts should tend to the regulation of supply and demand over the whole country, and ensure growing on the most useful lines and distribution to the best advantage.

Thirdly, you suggest the possibility of personal instruction. I feel this to be essential. Now, if ever, is the opportunity to increase the fertility and productiveness of the land. The weight of a crop varies so enormously according to the method of cultivation; hence the great importance of teaching the allotment holder the principles of intensive culture. We are all familiar with the sight of a small boy sweeping up road scrapings for the small garden; these and any leaf-mould that can be collected and dug into the soil at a considerable depth in the winter would produce very different crops from those we are accustomed to see. Another thing we have to learn is that large vegetables are not necessarily coarse. One has only to compare the mere look of a field crop of Parsnips or Carrots with those exhibited at the London and provincial shows. In the one case the root from crown to point is only 8 inches to 10 inches long; in the other, it may come to nearly 3 feet in length. A form of cultivation between these two extremes would not be impossible, and instruction as to how to achieve this result is a very great desideratum.

Finally, I should like to make a suggestion that has long been in my mind, and that is the possibility of starting co-operative piggeries. There seems no reason against, and every reason in favour of, having co-operative piggeries in connection with allotment gardens, as has been the custom in Belgium. Considering the enormous amount of green stuff—Cabbage stalks and the like, which are the inevitable refuse of allotments, combined with the remnants from the cottages of the holders, I think we should make a very real effort to produce the home-grown article, in view of the millions of pounds (sterling) worth of bacon annually imported.

In these, as in other directions, the present anxious time, while it emphasises the need, would seem also to suggest the opportunity of meeting that need.

LILLIAS HAMILTON (Warden).

Studley Horticultural and Agricultural College for Women.

You are rendering yeoman service to the nation by your article in your issue of the 6th inst. There is not much danger of there being a serious shortage of food in this country, but in view of the great armies at home and abroad, as well as the Navy (not to mention our wounded), huge demands for food must necessarily be made on us. The threat by the Germans to blockade our ports will cause us no alarm, but at the same time our food supply will not be increased as a result of submarine operations. It therefore behoves all not only to economise, but to see to it that every inch of land shall be made as fully productive as possible during the coming summer and autumn. Unfortunately, everybody does not read THE GARDEN, and the problem is how to get at those who fail to see your article. I suggest, therefore, that a copy of your article should be sent to all the leading London and provincial daily newspapers, and also to local papers, with a request for insertion. The expense of this would be lessened if one or other of the great news distributing agencies could be prevailed upon to render assistance in this direction, as I have no doubt it will do if a representation is made to it on patriotic grounds. Copies of the article might also with advantage be sent to local governing bodies which have to grow large crops for the inmates of workhouses, &c. In fact, every effort must be made to bring home to our people the necessity of growing all possible crops. The magnificent example set by the Dunfermline Horticultural Society is one which might well be followed by other societies. The Royal Horticultural Society is first and foremost in everything connected with the horticultural world. Could not the Council be induced to have all land available at Wisley planted with vegetables, and to have the same distributed to places where they are wanted? Large numbers of wounded soldiers are expected before long. These are to be centralised. I would therefore suggest that the Royal Horticultural Society should undertake to supply at least one hospital of wounded soldiers with vegetables. F.R.H.S.

I HAVE just seen the article in your admirable paper suggesting that local societies should take up the question of increasing our vegetable supplies. I may add that the Hayward's Heath and District Gardeners' Mutual Improvement Association is now trying to arrange for a lecture or debate on this subject at its meeting on March 3. I am wondering if any reader could assist me in obtaining a lecturer on this important work. I may point out that the Hayward's Heath Horticultural Society has resolved itself into a local branch for the purpose of collecting and packing fruit and vegetables for the Fleet, and sending to the head committee—the Vegetable Products Committee. I am sure that if something could be done so that the matter you are taking up could be forcibly put before the many head and single-handed gardeners, also cottagers, it would be successful.

G. PREVETT (Hon. Secretary).

The Rosery, Hayward's Heath.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Danger of Planting Pot-Bound Plants.—

I enclose two photographs portraying in a somewhat striking manner an instance of a disastrous result of planting a pot-bound plant. Photograph No. 1

1.—ROOTS OF A POT-BOUND PITTOSPORUM COLENZOI FIVE YEARS AFTER PLANTING.

shows how the roots have followed the concentricity given to them by the shape of the pot, until by persistent constriction they have so strangled the main stem (as shown in No. 2) that it has only required an extra puff of wind to cause complete severance. The plant is Pittosporum Colensoi, and was planted five years ago. It was a fine specimen for its age, having attained the height of 12 feet.—ALEX. M. WILSON.

Iris Tauri.—This handsome Juno Iris is well known to most hardy plantsmen, and is now in abundant flower here. Although it increases fairly well from offsets if given good treatment, seedlings raised in this country seem to make the strongest bulbs. It is, however, only once in a while that I. Tauri will seed in our climate, as its period of flowering is so early that there are few insects then about. A springtime characterised by a warm and sunny February will, as a rule, prove the forerunner of a plentiful quantity of seed on this and other allied varieties of the Iris group, and it is well worth while to take the pains to watch, gather and sow it, even though one must not expect flowers from the seedlings for at least four years. Such, at any rate, is my experience.—F. H. CHAPMAN, Rye.

Cultivation of Tropæolum speciosum.—I was interested in Mr. R. A. Earp's article on Tropæolum speciosum which appeared in the issue of THE GARDEN dated February 6, page 68, in which he says his friend informed him that it would only grow in Cornwall and the Highlands. Well, I think she was a great way out in so sweeping a statement, for I have seen it grown, perhaps not to perfection, but as near that condition as to matter but little. This was in Wigtownshire, Scotland, and but a few feet above sea-level. There it covered not only the railings which were intended for its support, but also Rhododendrons and various other evergreens, some of which were quite a distance from where I should imagine it had originally been planted. I do not know

whether Mr. Day, when he was a contributor to your columns, mentioned it or not, but I can assure you the masses of flame colour during the summer were quite a feature of the place. This was at Galloway House, Garlieston, Wigtownshire.

—CHARLES TROTT.

—Tropæolum speciosum, known here as Flame Flower or Scottish Creeper, is very largely grown in the Lake District, where we consider that it requires the kind of deep, rich soil which grows good Pansies. It likes a north or north-west position, as a rule, and prefers a living support to wire or string, though well-established plants will cling to anything provided. A more beautiful picture cannot be imagined than a sheet of the vivid scarlet flowers and light green leaves growing over an old Yew hedge. Flame Flower is rather capricious, and sometimes takes several seasons to become established. It has a curious habit, if its tastes are not provided for, of growing horizontally underground until a more congenial home is found. I have known plants which were set at one side of a hut to grow underneath the hut and appear above the ground at the opposite side, where they flourished exceedingly. When once settled, it will sometimes spread almost as rapidly as Convolvulus, and I have even heard it described as a weed.—SPINK, Carlisle, North Lancs.

Daffodils for the Garden.—I must thank "A Small Amateur," the Rev. J. Jacob and Mr. G. L. Wilson for their kind replies to my letter. I am specially grateful for the lists of Daffodils recommended by the first two as suitable for the ordinary garden, because, as I said in my first letter, catalogues are not much help to a novice searching for sorts likely to thrive in the garden. Even "X. and Sons'" famous catalogue, which has different marks for those sorts recommended for exhibition and those for the border, goes on to say about those marked as suitable for exhibition, "they are, however, in most cases also splendid border varieties," so that one does not get much "forarder." I see from the "Daffodil Year Book" of 1914 that the Narcissus committee of the Royal Horticultural Society recommend the following for the garden: Mme. de Graaff, Barrii conspicuus, Emperor, Sir Watkin, Empress, Lady Margaret Boscawen, Lucifer, White Lady, Weardale Perfection, Horace, Argent, Cassandra, Blackwell, Duke of Bedford, Seagull, Gloria Mundi, Golden Spur, Homespun, King Alfred and Poeticus recurvus. A novice looking at such a list would, I think, be justified in considering that as regards vigour of constitution and suitability for the garden all these twenty were much of a muchness. I am afraid, however, his faith in the judgment of those who sit in the seats of the mighty in the Daffodil world would be rather shaken when he sees in THE GARDEN of January 30 the superdaffodilist, the Rev. J. Jacob, state in reply to "poor 'J. R.' from the cold North" that Homespun and King Alfred are not "good garden plants in the way that Emperor and Barrii conspicuus are." Of course, this list is a first attempt. No doubt, as years roll on, it will be revised and expanded, and should prove of the utmost value.—J. R.

Shows, Schedules and Judges.—Mr. George Garner, in your issue of January 30, bears me out that the wording of schedules is too often ambiguous, and also admits that judges are not always what an exhibitor has a right to expect—competent. He thinks I am "rather hard on committees in reference to trade exhibitors," but that I "may have evidence of importance" to bear me out.

Yes, Sir, heaps of it. I am glad that Mr. Garner realises the value of trade exhibits, for undoubtedly in very many instances they form by far the biggest attraction in the tents at practically very little cost to the committee; but how often do we find that, instead of assisting the trade exhibitor, he is left till last, because "We must get Lord So-and-so's gardener to the station." That may be good policy; but it frequently happens that the trade exhibitor is due at another show next day, and a lengthy delay may upset his arrangements and not only prove a loss to him, but also to the committee who are expecting him to fill the space allotted. With regard to evidence to bear out my strictures, I will mention one or two instances out of many. For one show definite arrangements had been made as to time of arrival, &c. After a wait of two hours a conveyance arrived, and on reaching the show ground all the officials had left, the tents were in complete darkness, and the man in charge had no instructions and did not know which tent. In another case, after a wait of an hour and a half at the station, a small conveyance arrived (the only one employed) which could only take a portion of the exhibit, thus necessitating a second journey of nearly five miles. In many cases the trader—from necessity—arrives late in the evening. No information can be given him by the show officials as to lodgings, and frequently he—or they—have to spend the night in the tents. Another item prejudicial to trade exhibitors is that while they go, naturally, for "trade" at many shows, patrons and subscribers get a private view and are gone before the exhibitor is admitted. These are the people who would be most likely to do business; but the trader is precluded from getting it because he has not been admitted, and his cards cannot be exhibited until judging is completed and he is admitted. Where the exhibit is not in competition for money prizes, the exhibitor should be allowed to be at his post. I, with others, have frequently had to stay in a town an extra night because of delay in getting conveyances to reach the station in time, the private exhibitor being the first to get attention. Again, it is often found that on arrival at a show, the staging is not fixed, and much valuable time is lost. I do not

2.—SHOWING HOW THE MAIN STEM WAS STRANGLED.

plead for extra special consideration for the trade exhibitor, but many things might be improved to the comfort of the exhibitor and the advantage of the show. I would also commend "Scot Exhibitor's" remarks to show committees. It would be quite easy for a list of suitable lodgings to be kept by the secretary, and it would be much appreciated by exhibitors.—EXHIBITOR

LILACS AND THEIR CULTIVATION.

THERE are few flowering shrubs that appeal more strongly to those who appreciate fragrant blossoms and graceful contour than the Lilacs, yet it is safe to assert that in the majority of gardens they are the most neglected shrubs that one finds. Too often they are wedged between more or less solid blocks of coarse-growing

is essential, and if the soil is naturally wet this must be provided.

Lilacs on Their Own Roots.—Unfortunately, a great many of the best garden varieties are grafted or budded on the common Lilac, which always has a tendency to throw up suckers. Often these pass unnoticed until they have attained large dimensions and have ruined the choice variety that they should in the ordinary way have fostered. Some nurserymen supply these good varieties on their own roots, and it is well to secure these wherever possible; then the

are usually taken to the conservatory, where the atmospheric conditions are drier and the temperature lower; here they will remain in good condition for several weeks.

The Best Varieties.—There are a good many excellent garden varieties to select from, a number of them differing very slightly. The following are good and reliable for ordinary purposes: Single, white flowered—alba grandiflora, Marie Legraye, Mlle. Fernande Viger and Frau Bertha Dammann. Single-flowered coloured varieties—

Negro, deep purple; Othello, deep claret red; Dr. Mirabel, very erect panicles, deep claret red in bud, opening to rich purple; Gloire de la Rochelle, deep lilac blue; Pasteur, wine red; Philemon, dark red; Mme. F. Morel, large panicles of deep purple colour; Souvenir de Louis Späth and Charles X., deep red. Double flowers—Marie Lemoine, Miss Ellen Willmott and Mme. Abel Chatenay, white; Condercet, large panicles of lilac blue shade; President Grévy, blue flowers, edged rose; Maurice de Vilmorin, deep claret red; Dr. Troyanosky, very large panicles of azure blue flowers, which are rosy pink in the bud stage; Comte de Kerchove, rich rosy red, very free flowering; and La Tour d'Auvergne, violet purple. H.

DAFFODIL NOTES.

Shows and Their Dates.

The florist division of the Daffodil world is, naturally, thinking about the coming shows and wondering if they will all take place as usual. Through the courtesy and kind help of the several secretaries I am enabled to make a statement. The following exhibitions are definitely abandoned: Devon, Glamorganshire, Brecon, Huntingdonshire, Ipswich

and East of England, and Kingsbridge. At the time of writing (early February), the following is a list of the dates, names and venues of those that it is proposed to hold: April 13 and 14, Royal Horticultural Society, at Vincent Square; April 14, Herefordshire, at Hereford; April 14 and 15, Royal Horticultural Society of Ireland, at Ballis Bridge, Dublin; April 15, County Clare, at Ennis; April 15, Tewkesbury, at Tewkesbury; April 20, Lincolnshire, at Spilsby; April 21 and 22, Midland, at Birmingham; and April 24, Presteign, at Presteign. I have no news about the Kent, Surrey and Sussex show, and it is not settled yet about Cornwall. These gaps are unavoidable. Our country comes before our Daffodils. While it is a sign of patriotism to do all we can to carry on as usual, it is not always possible, and changes have to be made. I sincerely hope no untoward event will necessitate an abandonment of any of the above fixtures.

Fanny Currey.—Miss Currey was for so long a popular figure at London and Birmingham that I am sure some news of her in her enforced retirement will be welcome to many. The Warren Gardens at Lismore are entirely given up, and Miss O'Hara, her friend and companion, writes: "I am sorry not to be able to report

AN EFFECTIVE GROUPING OF LILACS AND OTHER HARDY SHRUBS.

evergreens, where it is impossible for them to properly ripen their wood each autumn and so ensure a bountiful display of blossom the following May. A valuable object-lesson in the proper planting of Lilacs may be seen any day of the year at Kew. In one instance a very large bed near the main gate is devoted to these charming shrubs, the varieties being so grouped as to give an excellent harmony of colours. Under the Lilacs, Winter Aconites and other very early flowering bulbs are planted, to provide a carpet of green and gold at a time when the Lilac bushes are devoid of foliage. At Bletchley Park, Bucks, Lilacs are freely dispersed among other shrubs by the side of the walks and carriage drives. The effect in May is most pleasing, especially where the Persian Lilac and Golden Chain or Laburnum are flowering together. There is surely no justification for the half-starved and overcrowded bushes that do duty in many gardens.

After all, Lilacs do not call for a great deal of special attention. True, they need deeply cultivated soil and a fairly liberal diet, and for this reason the ground should be well trenched and manured thoroughly with decayed manure before planting is done. The planting season extends from October till March. Good drainage

suckers, or a proportion of them, may be desirable rather than otherwise. But even here there is some danger, especially as the bushes attain a fairly large size. If too many of the suckers or basal shoots are allowed to remain, the plants are likely to get overcrowded, a state of affairs that must be strictly guarded against. In growing Lilacs we must fully bear in mind the fact that if we desire good flowers, the wood must be well ripened by exposure to light and air the previous autumn. Apart, however, from a thinning out of weak, useless shoots, and the removal of the flower-heads when the blossoms have faded, Lilacs do not need much pruning.

Their Value for Forcing.—During recent years quite a big industry has been brought into being, in France as well as at home, in forcing Lilacs into bloom from January until April. The plants used for this purpose are generally gaunt-looking specimens with a few very strong shoots, this condition having been brought about by severe disbudding for two or three years previously. As the plants are in pots they are easily managed, and are by no means difficult to force into bloom. They are gradually inured to a temperature of 65° Fahr., and lightly syringed overhead daily to assist the buds to burst. When in flower they

much improvement in her, though her health continues fairly good."

Honour for the Daffodil.—A Welsh Chancellor of the Exchequer has evidently solved to his own satisfaction the knotty problem of what is the national floral emblem of Wales. It used to be taken for granted that it was the Leek, but latterly that seemingly obvious fact has been challenged and a claim set up for the yellow Daffodil. The Chancellor seems to have decided the question, and who knows but that his decision will be, as it were, the making of the flower, so that in future we will have to say the Rose for England, the Thistle for Scotland, the Shamrock for Ireland, and the Daffodil for Wales. Readers may be asking themselves, "How do I know?" and "Why do I write of the Chancellor's decision?" A little episode that happened this week will make my meaning plain. My gardener having to go into Whitchurch on business, I asked him to call at the bank and get one of the new one pound notes with a Daffodil on. In due course he went to the bank, presented my cheque and asked for one of the new notes with a Daffodil on it. "Very sorry," said the cashier, "we have none. We'll have to get some made!" and forthwith, with profuse apologies, he gave him one of the new issue. The note was brought home, and I was told that it was the only kind they had at the bank, but that there was no Daffodil upon it! Visions of the bank innocents having been taken in by a wholesale forgery instantly rose up in my mind, but when I looked at the note the Daffodil was there all right. Problem: Find the Daffodil on a new one pound note. You, good reader, may not know it is there, and that our pet flower figures proudly on the official currency of Great Britain. It is the first time that Wales has been represented on it.

The Royal Horticultural Society's Classified List of Daffodil Names, 1914.—I have before me the first list that was issued by the Royal Horticultural Society in 1907. In round figures it contained 1,500 names. I have counted the number in that of 1914. Roughly speaking, there are 3,000, to which must be added the additions which the secretary of the Narcissus committee must have in his desk. But over and above all these there are all the Australian and New Zealand varieties, few of which seem to be registered, and then there is that vast multitude which "no man can number," all potentially crying out (to alter one word in a *great* song):

"We are coming, we are coming,
As our Fathers did of yore!
We are coming, Father Curtis,
Six hundred thousand more!"*

Yes; this *is* poetic licence, but the idea is all right. There are on their way to fame or the other thing far more new and unnamed varieties than anyone realises. I have an enormous number myself; Dr. Lower is only just starting; Mr. G. L. Wilson (Ireland) is in much the same position;

* The chorus of the famous recruiting song of the Northern States of America.

Mr. James Coey, I presume, is not letting the grass grow under his feet; Mr. England of Exeter must have something "good" in the making; Mr. Mallender and his co-worker, Mr. G. Stocks, are also on the warpath; Mr. Carne Ross and Captain Kitchen are probably not idle.

This is bewildering enough, but what of those "coming on" in the great dominions of New Zealand and Australia! Not the children of Lowe, Rhodes, Bradley, West, Selkirk, Buckland, Thomas and other well-known raisers, but those of the, comparatively speaking, unknown—of, let us say, Mr. H. E. Sharp of Oratia, New Zealand who grows 1,125 named varieties and who has been busy hybridising since 1906, yearly importing some of the best blood from the Old Country and Holland to keep himself up to date. By the way, he writes of Mauger's l'Avenir (1c) as one of the very best of market flowers, and that Victoria has stems 18 inches long! He did well last September at the Auckland Show. Then, to go to Australia, there is Mr. C. W. Higgins, a nephew of the great Higgins whose list for 1913-14 fairly staggered me by its expensive inclusiveness. He and his father and brother are enthusiasts, and busy as bees at the game of seedling raising,

SOME CULTURAL HINTS ON FREESIAS.

AS one whose business it is to handle a considerable number of bulbs, I have often been surprised at the comparatively small number of Freesias sold during the season. Why is this? The flowers open without much trouble, and no great heat is required; they come at a time when flowers are very scarce and much appreciated; no flower is more suitable for cutting; while the scent is most delightful, and remains fresh until the flower is almost dead. Having asked a question, I will endeavour to answer it. My belief is that the greater number of people who try to grow this beautiful flower grow it so badly that they give up in disgust. There seems to be no other logical reason why it is not more extensively grown.

The Reasons for Failure.—Let us now look for the probable cause of failure. First and foremost, I would say that late potting is more to blame for failures than anything else. The bulbs of this plant ripen very early, and if kept out of the soil long they lose much of their vitality,

LILACS FLOWERING BESIDE A CARRIAGE DRIVE IN THE GARDENS AT BLETCHLEY PARK, BUCKS.

inspired as they well may be by such men as Buckland, Bradley and Selkirk. I have had a long and interesting letter from "C. W.," in which he narrates his experiences of seed and pollen parents. It illustrates in a very striking way the old adage put into Daffodil language, "What's one variety's climate is another's poison."

Number of Seeds in a Pod.—I wonder what is the record number of seeds in a pod. Mr. Higgins' father once had a King Alfred \times calathinus with sixty in, and last year (1913-14) an Albatross \times Treasure Trove with fifty-two. My own biggest appears to be a Sidney \times Daybreak (Tazetta) with fifty-three. These little records are interesting.

JOSEPH JACOB.

and will never do themselves justice. Not once nor twice, but many times have I had experiments made in potting Freesias as soon as they arrive from France, which is generally about the last week in July, and others in a month or ten weeks' time. In nearly every case the early potted ones have done excellently, while those potted later have been so poor that they really have not paid for the trouble of planting, and one can easily imagine an amateur, on looking at such poor results, saying, "What a poor show. I will never trouble with those things again!" Let early potting, then, be the watchword. Now as to

Soil and Treatment. To flower Freesias well a good, sound soil is a necessity, for, unlike

Hyacinths, Daffodils, &c., the bloom is not produced on the bulb you buy, but on a new bulb which is produced from the old one. It will be seen, then, that this flower requires more real *growing* than does a Daffodil bloom, which is already formed within the bulb and only needs enticing out. Our Freesias are always potted in Kettering loam, to which is added a little Cocoanut fibre and sand to keep it open. After potting—about twelve bulbs are put in a 6-inch pot—they receive a gentle watering and are plunged in a cold frame and covered with about half an inch of fibre. Many growers are against any covering, but I have found that a light one keeps the soil moist and does no harm. A deep covering is harmful, as it draws up the young leaves and makes them weak.

Unless heavy rain occurs, the lights are left off the frame until cold nights come on, when a covering is necessary, but air must be given freely whenever the weather is fit.

The Growing Plants.—As soon as all the bulbs have made a start, it is well to remove the

been made, very little water should be given, but when in full growth they require a fair quantity. Treated on these lines our Freesias are always a success, though the ripening seasons of the bulbs will give better results in one year than another. Last year must have been very favourable for them, for we are now enjoying a record crop of bloom. Hardly a bulb has failed, and the pots have been full of strong, sturdy growths bearing double and even treble trusses of full-sized blooms. Before any were cut the plants were bristling with buds, and I said to our grower, "Now if amateurs once had a crop of Freesias like that, they would never be without them again."

Freesias are really very cheap to buy if—and it is a large "if"—they are grown as they should be; but if potted late and badly grown they are not worth pot or greenhouse room. To my mind the Freesia is far and away cheaper in proportion to the bloom it produces than the Roman Hyacinth, which, by the way, has of late steadily increased in price and decreased in quality, partly owing to the huge demand for the bulbs, which

stems or leaves, surmounted in the summer by myriads of blue flowers. These often open in May, and the display is continued sometimes until well into August. As its old specific name implies, it is a useful plant for old walls, but it is also excellent for planting in the interstices of stone pathways, while it is equally at home in a sunny spot in the rock garden or as a pot plant in the conservatory. Good loam that is fairly retentive of moisture suits this charming little plant. T. G.

WINTER GRIME IN LONDON SQUARES.

TO eyes unaccustomed to London grime and smoke, the blackness of the square gardens and also of the parks is very surprising, and when one hears of the wonderful gardening and the sums of money said to be lavished on them, I really think somebody must be rather to blame. Surely there are other good green shrubs for winter besides the ubiquitous Aucuba and Euonymus! Privet decidedly declines to come under the category of anything that is green in the winter. Hollies may be meritorious, but they are positively black at this season, so the aspect of both squares and parks is dismal and depressing to a degree. All who are unaccustomed to such surroundings feel that some effort should be made to combat this unsightly squalor, and I sincerely hope the London gardening ædiles will give some little attention to the cheering and brightening up of the winter parks and squares.

There is no need to go very far afield for wondrous novelties which might or might not answer in such dismal days as those endured last January. We have such cheerful and hardy things as the bright green *Griselinia littoralis*, so useful and hardy in smoky places in Yorkshire, where frost is not as severe as in the country. *Olearia Traversii* grows, perhaps, rather tall and tree-like, but *O. Fosteri*, bright green, would surely surprise the eye of the passerby. The well-known *O. Haastii* seems all but unknown here,

though it is of unimpeachable hardiness and vigour under smoky conditions. No doubt it flowers too late for the London seasoners, and its faded brown flower-heads are rather unsightly in the autumn; but even this is far superior to the average "square" shrub, and stands both pruning, drought and digging with sturdy cheerfulness.

But for winter massing there is one old plant of surpassing beauty which may be seen at the foot of the Serpentine, towards the top of the Dell, that surely should give a hint of what might be done. *Acanthus mollis* is the plant I mean, whose splendid foliage and rich green tone redeems that corner from the dreary uniform of blacks and dark, sooty tones that reign generally. No doubt the plant dies down in August and is then unsightly (it must not be confused with the smaller and more prickly *Acanthus*, which is then in beauty, but dies down in the winter), but with the first autumn rains it pushes up strong and green, rich and beautiful, as if it were spring

THE WALL BELLFLOWER, *CAMPANULA PORTENSCHLAGIANA*, GROWING BETWEEN FLAG-STONES.

fibre from the surface of the pot, and sticks must be put to the plants in good time to prevent them from tumbling about. Three or four very thin sticks—Bamboo tips are the best—should be put round the edge of each pot, and some very fine raffia laced round from one to another to form a kind of enclosure for the plants. Thick sticks and thick tying material look clumsy and unsightly. As soon as the nights get really cold and the plants stop growing, they should at once be removed into a cool greenhouse. (Ours are taken inside about November 1.) Otherwise the tips of the leaves will go brown and the general results will not be the best.

In the Greenhouse they should have a position as close to the glass as possible. The temperature should be only just enough to keep them going, say, a maximum of 55° by day and a minimum of 45° at night. As much air should be given as is possible without causing a chilly draught. I had forgotten to say that until some growth has

puts too great a drain upon the stocks grown, and partly owing to a number of very inclement seasons in the South of France, where they are grown.

I trust that my remarks may induce some amateurs, who have tried and failed, to give the Freesia another chance, and if the results are as good as I have enjoyed this year, I feel sure they will have a word of thanks, even if not verbally expressed.

J. DUNCAN PEARSON.

The Nurseries, Lowdham, Notts.

THE WALL BELLFLOWER.

THE Campanula or Bellflower in the accompanying illustration is one of the hardiest and most easily grown of all the dwarf section, yet it is at the same time a very charming and useful plant. Its modern name is *C. portenschlagiana*, though it is probably better known in gardens under its old cognomen of *C. muralis*. As will be seen, the plant makes a large, spreading tuft of green

and in London at least is a plant of the greatest value. Having spent many hours in vainly trying to eradicate this lovely but too overpowering plant in Southern gardens, I am all the more anxious to atone for my persecution by praising it in Northern counties, where its seedlings do not come up ubiquitously and where its beauty of form and colouring is so precious in the winter. Just fancy the effect if Portman Square or St. James' Square had bold clumps of this foliage near the railings in place of a Lilac or Privet bush, and how greatly the dreary, stiff beds of bulbs in the Park would be improved if they had a few bold groups of such foliage on the grass.

A few plants of the good old Siberian Saxifrages (Megaseas) would always be green and effective; yet where do you see them? All the money seems spent on things that need replacing, rather than on making green settings for a few cheerful spring flowers when spring does venture to come North, and it is high time a protest should be made.

EDWARD H. WOODALL

LILIUM AURATUM IN SCOTLAND AND JAPAN.

AMONG the uniformly charming and illuminating articles in your columns on "Some Hardy Lilies," by Sir Herbert Maxwell, the account of *L. auratum* stands out with peculiar fascination for myself, because it recalls some cherished memories of what he justly terms "the most gorgeous of all flowers hardy in the climate of the British Isles." To begin with, let me say that what I have seen entirely confirms Sir Herbert's views on such points as the suitability of peat and of the humid atmosphere and cool soil of the West Coast, and that the presence of tree roots in the soil is no detriment.

The grandest display of *L. auratum* I ever saw in this country—and it continued for a number of years—was at Torridon House, on the Inner Loch Torridon on the West Coast of Ross-shire. My friend the late Mr. Duncan Darroch of Torridon and Gourrock, though by no means posing as a horticulturist, made *L. auratum* a hobby. When in London in the winter, he would personally attend the early morning sales of newly arrived bulbs and secure the largest of them at comparatively small prices. I think it was in the early eighties that he commenced a long series of annual purchases of these bulbs. Torridon House stands at the top of a plateau sloping gently to the seashore, and bounded on the west by a rushing, rocky stream spanned by a footbridge that leads to the enclosed gardens. Above the footbridge, at the top of the river bank opposite

the house, a level strip of peaty land some 50 yards or 60 yards long by, perhaps, 15 yards or 20 yards wide, was surrounded by a deer and rabbit proof fence, was trenched, and was planted with a few *Rhododendrons*.

In all parts of this peaty plot, sometimes in rows, sometimes in clumps, the bulbs of *L. auratum* found a congenial home. They flourished exceedingly. Every year there was a profusion of magnificent flowers. I have seen many tall flowering stalks ranging up to 10 feet in height. The taller ones were always carefully measured and the measurements recorded. They were covered with the splendid gold-striped

early flowering strain of *auratum* would make a handsome fortune. The last time I saw the Torridon Lily garden was in 1897. Some years later Mr. Darroch told me that his *auratums* had ceased to flourish; he knew not why. Doubtless he might have said, "An enemy hath done this!" That enemy Sir Herbert Maxwell would have boldly tackled and expelled.

It was in July, 1899, that I first saw *L. auratum* at home. I was staying at Gochi, a seaside resort near the Treaty Port of Naoetsu, on the north side of the main island of Japan, facing the Sea of Japan, and with a view of the Island of Sado, where there is gold. Driven hurriedly home from a ramble

on the shore by a thunderstorm with tropical rain, I was passing along a new military road when I saw at the top of the bank of a cutting what looked like a dragged flower-stalk of *auratum*. A spur of the central range of volcanic mountains here runs out towards the sea, the lower shoulders and slopes clothed with forest, where charcoal-burning is extensively pursued. Next day I wended my way to the beginning of that cutting. The cottage of a charcoal-burner by the roadside had, I remember, a row of fine Balsams in its little garden. Close by, a path entered the forest. I followed it a few yards, and lo! there was *L. auratum* in all its glory. Everywhere, amid the thickest trees and densest undergrowth, as well as in places where lovely glades opened out in the forest, even among rocks and by the sides of rivulets, our golden Lily in countless multitude reared its gorgeous flowers.

There were other flowers in that beautiful forest, such as brilliant Tiger Lilies and tall blue Campanulas, but they seemed of small account. In subsequent years I have often seen *L. auratum* growing even more luxuriantly and abundantly in other parts of Japan, mostly on hillsides; but I never again enjoyed it quite so much as on that first introduction. The individual blooms were of large size, but there were few on a stalk.

J. H. D.

PAPAVER ORIENTALE LADY FREDERICK MOORE, A CHARMING NEW ORIENTAL POPPY OF SALMON-PINK COLOUR.

flowers. I have counted 200 flowers on a single stalk. Mr. Darroch told me that he had no special system of cultivation, but I believe the Lilies got a top-dressing in the winter. He said the bulbs always did best in the third year, and after that went back. The *Rhododendrons* seemed to have no bad effect. Early frosts are not usual on the West Coast, but many of the *auratums* never opened their flowers unless they were cut and taken indoors.

Another Ross-shire Lily-lover, the late Sir Kenneth Mackenzie of Gairloch, used to say that any gardener who could produce an

A NEW ORIENTAL POPPY.

The flowers illustrated on this page represent a beautiful new variety of *Papaver orientale* named Lady Frederick Moore. When shown before the floral committee of the Royal Horticultural Society in June last year, this charming hardy flower received an award of merit. The blossoms are very large, measuring as much as seven inches in diameter, and the colour is a delightful soft shade of clear salmon pink. As will be seen in the illustration, each petal has at its base a large conspicuous blotch of maroon. The stems are erect and stiff, hence it should prove an excellent variety for cutting. It was raised by Mr. Amos Perry, Hardy Plant Farm, Enfield, to whom we are indebted for the introduction of many good new hardy plants

THE BEST WHITE SWEET PEAS.

THERE is no section of Sweet Peas causing so much discussion as those with white flowers. The trade growers, as well as amateurs, are undecided as to the variety that is to lead this year. From a garden point of view and for the cut-flower trade Nora Unwin (Special Stock) stands first. This selection is distinct from the original stock, both in wings and keel; the standard is perfect. The flowers of this variety make a first-rate market bunch, and travel and stand well.

Some of the leading amateur growers in the North are growing King White and Edna May; the champions of the South are strong on Constance Hinton and King White. In my notes made last year at several trade trials that I had the pleasure

Florence Wright, Moneymaker, Norvic and Stanley Crisp, all with white seeds; and Constance Hinton, Mrs. Sankey Spencer and Havant White, with black seeds. These are all to be planted out in April for comparison. I hope to have the pleasure of inspecting them when in bloom. Here is what we want in an ideal white: Substance of Dorothy Eckford, form and size of King White, on Moneymaker stems.

T. B. L.

THE FUNGOID DISEASE OF SNOWDROPS.

READERS who are fond of the Snowdrop will do well to look through their plants of this exquisite flower to observe if any of them are affected by the fungoid disease peculiar to the Fair Maids of February, viz., *Botrytis galanthina*. It

is specially objectionable in collections comprising

Unaffected bulbs, which may even have been quite close to those attacked and are lifted at the same time, may be dipped in a weak solution of Condry's Fluid and replanted. I have also dusted them with flowers of sulphur before replanting, but the fluid is probably the safer, as more likely to prevent the disease from acquiring a foothold. I also dust the soil about the plants with sulphur.

The origin of this disease in gardens is obscure, but I have observed that it is more likely to appear in changeable weather than in that which is dry and settled. Frequent alternations of frost, snow, sleet and rain, with mild, sunny intervals, appear to be specially dangerous. It appears to make no difference whether the Snowdrops are on bare ground or in grass, and I can recollect finding this *Botrytis* very prevalent among plants which were in thousands in grass under trees, and which had been established and naturalised for many years. These were common single Snowdrops. The disease must be sporadic or of modern date, otherwise the Snowdrops would have been much fewer than they were there.

Dr. M. C. Cooke stated that this disease was first observed in 1873, and that it "threatened to be very destructive in the North," but "has never given much trouble in the South." The late Mr. James Allen of Shepton Mallet, who raised so many choice Snowdrops, informed me, however, from time to time that he had lost many Snowdrops from this pest.

In my former garden in this county (Kirkcudbright) *Botrytis galanthina* appeared at intervals, and gave me a good deal of trouble, seeming to be specially virulent with such Snowdrops as *Galanthus Ikariae* and *G. byzantinus*. In my present garden, which is more exposed, I have never seen it during the ten years or so I have had this house, although I removed as many of my Snowdrops as I could, and would have expected that the *Botrytis* might have been transferred with the bulbs. I am always living in fear of its appearance.

S. ARNOTT.

Maxwelltown, Dumfries.

ROSE ELECTRA PLANTED IN A LARGE BED AND RAMBLING OVER ROUGH SUPPORTS.

of inspecting, I have Nora Unwin as the best garden variety and King White for exhibition. The latter has quite a distinct form of standard, broad and erect, pure white, and produces nearly all fours on a stem. Between Florence Wright and Edna May there was little difference. They are certainly better than most stocks of Etta Dyke, which has had a good run, yet there are some stocks that have been carefully grown and handled which are almost, if not quite, as good as the newer sorts. Moneymaker is without a doubt the longest-stemmed variety we have; it comes mixed in type only. Constance Hinton is a black-seeded variety. There is little, if any, difference between this and Mrs. Sankey Spencer, introduced in 1909. I have no hope of a black-seeded white topping the list as a pure white.

The other day I had the pleasure of inspecting an interesting set of trials. The whites included Etta Dyke, Nora Unwin, King White, Edna May,

rare species or varieties, seeing that they are usually in small numbers and can least be spared. The presence of the disease is noticeable from the time the plants appear above ground, when the development of the leaves and flowers is checked and the whole appearance disfigured. A white or greyish mould begins to appear about the neck of the plant, and, if left alone, spreads over the leaves and flowers. If the plants are lifted about this latter stage, the bulbs will be seen to be marked with black marks, or sclerotia, and they will be quite soft when pressed. Even when the presence of the disease is found at an early stage, the bulbs are soft and in a decaying state. The trouble should be attacked as soon as it is detected, and there is no really satisfactory treatment of the affected bulbs except the drastic one of burning them to prevent the spread of the disease. If the bulbs are removed as soon as the *Botrytis* appears, there is little danger of its spreading.

WHERE large, informal beds are to be filled with flowering shrubs, it would be difficult to conceive anything more beautiful than the Rambler Rose Electra, grown in the way shown in the accompanying illustration. It is of a vigorous character, and if given a few rough supports, such as forked trunks of small trees or branches of larger ones, will quickly fling its luxuriant growths over them, and in the summer create a picture of rare beauty. It is classed by the National Rose Society as a multiflora-scandens Rose, and was first put into commerce in 1900. The flowers are pale yellow in colour, and the plant does well on its own roots, being easily rooted from cuttings, preferably made of half-ripened wood, at the end of July or early in August, and rooted in pots of sandy soil plunged in Cocoanut fibre in a greenhouse or frame. Cuttings, a foot or rather more in length, can also be made in October or November from wood that has been produced the same year, and planted in sandy soil outdoors.

F. B. H.

RAMBLER ROSE ELECTRA.

SEASONABLE NOTES ON AURICULAS.

THERE are three classes or groups of Auricula—the show, which embraces green-edged, grey-edged, white-edged and selfs; alpinas, which are devoid of all meal or farina, either on the foliage or flowers; and the border varieties. The latter are well adapted for the rock garden and flower border, where small groups of one kind are often planted with splendid results. The show and alpinas are usually grown in pots and given the shelter of a cold frame, but it must be distinctly understood that only hardy treatment should be meted out to the Auricula.

Seasonable Hints.—Fanciers term February an active month, and this is certainly true if the weather is open and mild. More water may be given, and we should now aim at keeping each plant just moist. Light at this season is a most important factor in promoting sturdy growth, and if the glass is at all dirty, it ought to be washed immediately. Plenty of ventilation is essential, but cold, cutting, frosty winds must be avoided. Although the Auricula is hardy, it is advisable to protect the plants from sharp frosts from now until the flowers are removed, or the spike may be injured just as it begins to push up.

Offsets.—Some time in this month I always examine the collection, and all offsets large enough for removal are taken off. Many of them will possess roots, but others will not, and may in consequence be treated as ordinary cuttings. Several are placed around the side of a small pot which has been filled with sandy soil, and, if kept close for a few weeks in a hand-light or frame, roots will soon appear, when a separate pot can be given each rooted cutting. The larger offsets with a fair quantity of roots attached should be potted in 3-inch pots, the rooting medium consisting of the best fibrous loam three parts, leaf-mould one part, and a sprinkling of sharp sand to render the whole porous. The receptacles usually chosen for Auriculas are known as "long thumbs," and they are one-third filled with either crushed potsherds or broken brick rubble.

Repotting Offsets.—Those taken at the present time will require a larger pot in a few months, and if given proper attention, especially in regard to watering, they will be nice, healthy plants next season, when some stout spikes of bloom may reasonably be expected. A few offsets are taken in August, and where such work was carried out last year a larger receptacle will now be needed by all those that have filled their pots with roots. Employ the same kind of compost as mentioned above; and make it fairly firm. If woolly aphids are present, sprinkle the plants over with tobacco powder or apply a little methylated spirit with a camel-hair brush.

Seedlings.—In some collections seedlings are raised, and they may also now receive attention. Tiny plants with two or three small leaves may be pricked off into boxes of rather fine soil, about an inch apart. When sufficient progress has been made so that the leaves cover the surface, the seedlings ought to be given a separate existence. The seed-pans must not be discarded, as germination is often a slow and irregular process, the seeds sometimes remaining for twelve months in the soil before germinating. These laggards often prove to be the finest of all, and are then well worth waiting for. Seedlings must not be kept quite so dry at the base as flowering plants.

T. W. B.

THE WART DISEASE OF POTATOES.

THE Board of Agriculture, and Fisheries desire to remind all occupiers of premises declared infected for the purpose of the Wart Disease of Potatoes Order, or of premises situated within an infected area, that it is illegal to plant any Potatoes on such premises unless a licence has previously been obtained from an inspector of the Board or of the local authority. The penalty for any contravention of the Order is a fine not exceeding £10. Such licences can, however, as a rule be obtained, on application to the Board, by any occupier who undertakes to obtain from a dealer approved by the Board one or more of the varieties of Potato here referred to, all of which have been tested, some of them for several years, and have been found to resist wart disease under ordinary circumstances. Seed Potatoes of resistant types saved from the grower's own crop will be permitted. The Board will, on application, send a list of dealers who have undertaken to stock these Potatoes.

Milecross Early (Dickson).—White, round, not liable to ordinary Potato disease (Phytophthora); matures rapidly, haulm strong and quality good; a first early.

Conquest (Findlay).—White, round, heavy cropping, second-early Potato of good quality; must be earthed up high, as tubers are produced near surface.

King George V. (Butler).—Second-early. An elongated, oval tuber, skin netted, eyes shallow, haulm strong. An excellent cropper. Quality moderate; flower white.

Favourite (Dobbie).—A second-early, round in shape, white flower; an excellent Potato.

Supreme (Sutton).—A second-early of pebble shape, white flower, suited to garden cultivation.

Great Scot (McAlister).—A very good second-early; white and round; eyes rather deep; haulm robust; a very heavy cropper under good cultivation. Quality excellent; flower white.

Schoolmaster.—A second-early, white-skinned and round; crops well, but is liable to ordinary disease. Not a good keeper.

Jeanie Deans (Findlay).—A fine oval Potato with strong haulm and white flower. Crops heavily on light, rich soils.

Abundance (Sutton).—A well-known heavy-cropping, late variety, oval in shape, of good quality, rather liable to ordinary disease.

Crofter (Dobbie).—A late oval Potato of good quality; liable to ordinary disease. Flower white.

Culdees Castle.—A pebble-shaped variety, not quite so strong in the haulm as Crofter, and liable

to produce more seed size tubers on light soil. Does well under garden cultivation. Flower white.

Burnhouse Beauty (Dobbie).—A new early maincrop, bearing a large crop of flattish, round, white Potatoes. Flower lavender and white.

Provost (Dobbie).—A late, white, round Potato possessing strong haulm and white flowers; well suited to garden cultivation.

The Admiral (Dobbie).—A late variety, white-skinned and round. Haulm medium, a heavy cropper and good disease resister. Quality excellent; flower white.

Irish Queen.—Tubers round, eyes rather deep, haulm strong. Excellent cropper. Keeps late into season. Flower purple.

St. Malo Kidney.—Tubers coarse, kidney-shaped. Haulm robust. Not a good keeper.

Laird (Davie).—Roundish tuber, flesh white. A robust variety that crops heavily on well-prepared medium loams. Quality excellent.

Flourball (Sutton).—Well-known late variety, round and pink-skinned. Eyes rather deep,

POTATOES ATTACKED BY THE WART DISEASE.

haulm straggling, with bronzing on stems when exposed. Quality very good; flower white.

The Lochar (Farish).—A new maincrop variety of a sturdy growth. Crops heavily on some soils.

Golden Wonder (Brown).—A late white-fleshed kidney with yellowish brown tinge on skin. The "seed" should be a good size, and if unsprouted should be planted before the end of March, as the variety requires a long growing season. Liberal manuring is essential, and in gardens bastard trenching is recommended. It is possessed of excellent quality, and is one of the best late-keeping Potatoes. Flower mauve-tipped white.

Peacemaker (Scarlett).—Is similar to Golden Wonder.

Langworthy (Niven).—A late kidney-shaped Potato possessing white skin and flesh. Tubers may be recognised by the characteristic tapering "heel." Quality excellent. Same treatment as for Golden Wonder. Flower mauve-tipped white.

What's Wanted (Niven).—Shape not so constant as in Langworthy. It bears more tubers, but of a smaller size. In other respects very similar.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Permanent Vines.—When the bunches have set, lose no time in removing the surplus bunches. At the same time cut out all growth which is not required to furnish the trellis. Laterals must be stopped regularly, and the shoots may now be carefully secured to their permanent place on the trellis. The roots will be in need of a good watering. If so, diluted farmyard drainings should be afforded. A night temperature of 65° or 70° will not be too much at this stage.

Cucumbers.—Pay timely attention to the stopping and regulating of lateral growths, and when the leading growth has covered about three parts of the trellis, this also should be stopped. Add small quantities of fibrous loam and flaky leaf-mould to the roots as they appear, and occasionally sprinkle a little artificial manure over the rooting area. Syringe the foliage regularly and keep a moist atmosphere at all times. Make further sowings as the supply demands.

Tomatoes.—Plants raised in the autumn should now be setting their fruits. A minimum temperature of 60° must be maintained. The atmosphere must be kept buoyant by the careful use of the ventilators and a brisk heat in the hot-water pipes. The flowers must be carefully fertilised at midday. Keep later plants growing near to the glass, and see that the glass is quite clean.

Plants Under Glass.

Cannas.—The whole of these plants may now be shaken out and repotted. It is easy to increase good varieties by carefully dividing the roots. All the roots must be more or less divided, retaining only the most promising portions, unless it is desired to increase the stock. The Canna is a gross-feeding plant and needs a rich compost in which to thrive.

Begonias.—The tubers which have been resting may now be started into growth. Place them in clean, sifted leaf-mould in shallow boxes till growth commences, when they may be potted into their flowering pots and kept growing in a warm, moist house. Extra large tubers may be divided if increase of stock is desired. Seeds may now be sown in pots or pans. The utmost care will be needed in handling the seeds, which are very minute. Sprinkle a small quantity of sand over them. When sown, cover the pan with a piece of glass and place in a brisk heat.

Coleus thyrsoides.—These may now be cut back with a view to making cuttings for propagation. Some of the most promising of last year's struck plants may be selected for potting on. These will make fine specimens for another season. This plant may also be propagated from seeds.

The Flower Garden.

Seed-Sowing.—Seeds of various plants such as *Lobelia*, *Nicotiana sylvestris*, *N. affinis*, *Ricinus*, *Grevilleas*, *Artemisia*, *Arctotis*, *Dimorphotheca*, *Carnation*, *Petunias* and *Golden Feather*, may be sown now. Prick out seedlings which were sown at the end of last month before they become too crowded in the seed-pans.

Calceolarias.—If extra large plants are required, some that were rooted in frames in the autumn may be potted into 3-inch pots. *C. amplexicaulis* makes a fine individual subject by placing three or four plants in a 6-inch pot, keeping the plants neatly secured to stakes. These will be found useful for massing in the mixed border or for dot plants with other suitable subjects.

Salvia patens.—This delightful plant may be increased by cuttings. The tubers which were stored in the autumn may now be potted up and placed in a warm, moist house, where they will soon make growths suitable for cuttings.

Salvia Blue Beard.—I find this lovely purple Sage flowers more profusely by sowing early and allowing the plants to become somewhat starved in their pots or boxes before planting out.

The Hardy Fruit Garden.

Strawberries.—As soon as the ground is in suitable condition, give the beds a good dusting

with well-seasoned soot; then run the hoe between the plants and clear away weeds and dead foliage. It is possible that some of the plants put out in the autumn may have become loose in the ground through frost. These must be carefully made firm by treading. Old plantations should receive a good mulching with manure.

Protecting Materials.—When the weather is unfit for outdoor work, the opportunity should be taken to overhaul nets and other coverings which are used for protection against late frosts. Some of the nets which are not torn too badly may be mended with tarred twine.

The Kitchen Garden.

Cabbage.—The mild winter has caused the first batch of Cabbage to turn in prematurely, and to prevent a break in the supply any plants still remaining in the seed-bed should be put out, also fill up any gaps in the latest batch. When the ground is dry enough, the hoe must be used between the plants and soot liberally used. A sowing of an approved early variety may be made now in boxes and placed in a house of moderate warmth.

Onions.—Take the first opportunity when the ground is in suitable condition to sow the main crop of Onions. Make the ground firm by treading; then rake the surface fine, after which the seeds may be sown in drills 16 inches apart and about an inch deep.

Carrots in Frames.—As soon as the plants are well above the ground, thin them to about three inches apart. Afterwards water with a fine-rosed can to settle the soil about the roots. Admit air to the frames whenever the weather will allow. Make another sowing in a cold frame.

French Beans.—To keep up a good supply, sowings must be made every ten days. Sow about six seeds in an 8-inch pot and use a rich compost. When the plants are fruiting, plenty of stimulants must be given. The foliage must also be well syringed two or three times a day, or red spider will put in an appearance.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

The Herb Border.—No kitchen garden is complete without its herb border. This requires renewing from time to time, as some of its occupants become overgrown and others exhausted. Most herbs are easily raised from seed, and when making a new herb border room should be left for sowing later on such annual varieties as Chervil or Borage. Mint, Thyme, Tarragon and Sage are perhaps the ones most frequently demanded in the kitchen. Plants of Mint and Tarragon force in heat very readily, so that it is a simple matter to keep up the supply of these during the winter and early spring.

Horseradish.—This is a plant that can hardly be grown too large for kitchen use. The small pieces of roots or crowns should be preserved for making a new plantation. Being a very deep-rooting plant, care should be taken when digging up the roots that all of them are removed, otherwise any pieces left in the ground may give future trouble when they commence to grow, perhaps in the midst of a bed of small seedlings.

Seakale.—Small pieces of roots cut off from the crowns which were lifted for forcing should be cut into pieces about four inches or five inches in length and laid closely together in boxes of sandy soil. A cold frame will be all that is needed to start the root cuttings into growth. These will all form crowns ready for planting out later on. The piece of ground which is to become the new Seakale plot should be dug and manured well in advance.

Fruit Under Glass.

Early Vinery.—The temperature of this house should be advanced a little now that growth is making quick progress. As the bunches appear,

and when it is possible to distinguish between well-shaped bunches and the unshapely and small ones, the undesirable ones should be removed, so as to lessen the tax upon the Vines. With shy-setting varieties, such as Muscat of Alexandria, it is best to leave a surplus number of bunches in the event of any not setting evenly. A drier atmosphere should prevail during the time the Vines are in flower.

Strawberries.—More of these should be brought indoors from time to time, keeping in view that the later batches do not require so much time to reach the ripening stage. Plants placed in heat now will, under good conditions, produce ripe fruit during early May.

The Flower Garden.

The Rock Garden.—Any alterations or additions to this garden should be made before the season is any further advanced, so that the stones and soil may get firmly settled in time to allow the planting of the various subjects. After this date snails will become more numerous and active, therefore a sharp look-out should be kept. The young growths of *Gypsophilas* seem to have an especial attraction for snails. A good preventive is to spread fine ashes or gritty sand around the plants likely to be attacked.

Lobelias.—Seed of dwarf bedding Lobelias should be sown now in heat, so that nice plants may develop by bedding-out-time. Good varieties may be propagated from cuttings, which root very readily in the stove. These, in turn, can be topped again, making it possible to raise a large quantity in a very short time.

Ageratums, like Lobelias, are very easily rooted in heat, and a start should be made to propagate them now. After the first batch of cuttings has been rooted, the old stock plants can be dispensed with, as young plants are much more free. Ageratums can also be raised from seed, which is best sown this month.

Box Edging.—Whenever the weather is favourable, commence relaying any portions of this edging plant which require repairing or renewal. The ordinary dwarf Boxwood does not require relaying frequently, but the tree variety, to be kept in a smart, trim condition, requires relaying every third or fourth year, as it is a very vigorous grower.

Shrub Planting.—All arrears of this work must now be hurried on, as many deciduous subjects are showing signs of growth. The planting of evergreens is better done after this date, but should not be deferred too long.

The Wild Garden.—Many plants in this garden need periodical replanting to keep them in good condition. Particularly is this so when the garden itself is of very poor soil. Manure and humus or spent potting soil should be worked in before the plants are returned to their various quarters. Several shrubs will need attention in the matter of pruning before growth commences.

Plants Under Glass.

Euphorbia jacquiniæflora.—This subject will now be passing out of flower, and should be rested for two months. It should, however, receive an occasional watering, just sufficient to keep the plants alive. While at rest the plants may be removed to a cooler house, but should not be subjected to a lower temperature than 50°.

Poinsettia pulcherrima may be given the same treatment as the above.

Gardenias.—To keep up a constant supply of these fragrant flowers, it is necessary to propagate young plants from cuttings at different seasons of the year. Cuttings root freely in a close propagating-frame where there is plenty of bottom-heat at command. Gardenias being so subject to attacks from mealy bug and other insects, sponging and spraying with insecticides must be done almost unceasingly.

Violets.—Young runners in frames which were propagated in August and September should be looked over occasionally, and all side growths and suckers removed. The lights on these frames can now be dispensed with altogether, as the plants must be hardened off ready for planting out next month.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine Bart.)

Castlemilk Gardens, Lockerbie, N.B.

SOME NEWER GARDEN ROSES OF UNCOMMON TYPE.

THERE are always plenty of novelties annually announced in the Hybrid Tea class—far too many, I think; but among other classes of the wonderful Rose family there seems to be a comparatively slow advance. Perhaps I might make exception to this statement as regards the Polyantha Roses, for they are multiplying very rapidly. In this group we have one or two that seem quite departures from the usual type, one especially,

Rodhatte (Red Riding Hood) being extremely decorative, and doubtless very closely related to the Hybrid Teas or Monthlies. The flowers are semi-double, of vivid red colour, and they are of quite large size for the class. For massing, it will be most useful and a worthy companion to Fabvier. Then there is

Tip Top, a delightful Rose with coppery orange flowers heavily shaded with purple. The buds are of exquisite shape, each one a perfect show Rose in miniature.

Gruss an Aachen is quite large, almost large enough for a front-row flower of an exhibition box. The blooms are produced in clusters, and are of a lovely creamy pink shade, with buds of orange red and yellow. It is a delightful Rose and should be in every garden.

Yvonne Rabier appears to be a hybrid of *Rosa wichuraiana* with dwarf spreading growth, ever-blooming habit, and clusters of snow white blossoms as large as, and not unlike, the old Rose *Mme. Plantier*, which was once such a favourite of Sir Joseph Paxton. For massing, or any place where a white flower is needed, this Rose will be valuable. In violent contrast to it is

Merveille des Rouges, one of the most brilliant of the Polyanthas, and probably a cross between Fabvier and a Polyantha. I saw it in May at the raiser's nurseries in Lyons, and it was a wonderful sight and well named. I believe it will be more useful than *Erna Teschendorff*, for this grand-coloured Polyantha was terribly spoilt by mildew nearly the whole of last summer, the mildew affecting even the flowers. Among Rugosa or Japanese Roses we have two grand singles in *Carmen* and *Georges Cain*, both of brilliant colouring, far superior to the type. In the wonderful new group, the Pernetianas, there is a great acquisition in

Louise Catherine Breslau, a Rose that only needs to be known to be wanted by everyone, its colour, a coppery orange, shaded chrome yellow, with coral red buds, being most distinct and novel.

Mme. Ruan and Willowmere are also both charming in colour and resemble largely the Lyons Rose.

Louis Barbier is another variety that has not yet received the attention it deserves. Its semi-double flowers are of a most exquisite mixture of coppery red and yellow, with tints of purple and orange. As a pillar or free bush it will be delightful, and its mahogany-coloured wood is also attractive.

Two lovely singles are *Alexandra Zarifi* and *Mrs. A. Kingsmill*, both excellent additions, the former a fine erect grower with charming long buds, and the latter like a dwarf-growing *Rosa sinica Anemone*, with the colours reversed.

Rosa Moyesi is a most uncommon single Rose of great beauty. Its colour is a sort of brown

crimson, quite unique among Roses, and it may be the forerunner of some good things. I have successfully used it as the pollen parent upon the Hybrid Teas, and look forward to some interesting breaks.

Among Monthly Roses, in *Mrs. Edward Clayton*, *Laure de Broglie* and *Mlle. de la Vallette* we have a trio of good things, distinct and beautiful, and

Gruss an Dresden is even more brilliant than the very brilliant *Leuchtfleur*, from which great things, as a decorative Rose, are expected. The Hybrid Multifloras, that apparently spring from Trier, directly or indirectly, will fill a gap in perpetual-flowering Roses of a free, shrub-like habit. Of these, *Danæ*, *Moonlight*, *Daphne*, *Adrian Riverchon* and *Schiller* are most worthy of cultivation, and should be in every collection where these uncommon Roses are valued.

Queen of the Musks is very pretty, and perhaps should be grouped with the last named. It is practically always in bloom.

Miss Flora Mitten is one of the most charming single Roses we have received for some time, at least among the climbing section. It is a seedling of *Rosa brunoniana*, and makes shoots 12 feet to 15 feet in length in a season. The flowers are very large, some 4 inches to 5 inches across, and are produced in immense trusses of twenty to thirty blooms. They are of a rich, clear pink colour, with lighter centre, and set off by a fine mass of golden stamens. This fine novelty is almost perpetual, and will undoubtedly be one of our best climbing Roses. Another beautiful single Rambler is

Silver Moon. Its flowers have a resemblance to what one might imagine a single *Frau Karl Druschki* would be like; they are produced in nice clusters, and the plant has a wealth of beautiful glistening foliage.

DANECROFT.

THE CLOUD GRASS.

IN those gardens where Sweet Peas are grown largely for house decoration, when cut there is usually a difficulty in securing enough foliage to arrange with the blossoms, as the removal of their own leaves and tendrils on a large scale means the curtailment of the floral display. One of the most suitable and beautiful plants for use in conjunction with Sweet Peas when cut is the dainty little Grass known as *Agrostis nebuloza*, the Cloud Grass, a name that is most suitable on account of the gauze-like appearance of the plant when in flower, the tiny, brownish red blossoms on the very thin and much-branched stems creating a picture that for gracefulness and quiet beauty can hardly be surpassed in the plant world. This Grass possesses the merit of being easy to grow; hence its inclusion in any garden ought not to be attended with difficulty. Most seedsmen supply seeds, and from a packet of these a large number of plants can quickly be raised. Like the Sweet Pea, this Grass is a true annual; hence seeds must be sown every spring, the end of March or early in April being a good time. It will thrive in any soil that has been thoroughly dug and well drained, and the seeds should be sown where the plants are intended to grow. As soon as the seedlings are an inch or so high it will be necessary to thin them so that they stand at least six inches apart, as the flower-stems, which usually grow about eighteen inches high, branch very freely and need considerable room for their proper development. In addition to its usefulness in conjunction with Sweet Peas, this Grass may be utilised for other flowers which are of a graceful character.

H.

BOOKS.

Trees and Shrubs Hardy in the British Isles.*

This work makes a very important addition to horticultural literature, for it presents in easily understood language excellent descriptions of 3,000 or more hardy trees and shrubs, including many of the new Chinese introductions, together with general instructions on cultivation and hints on the treatment of those plants which require special care. The need for such a work has long been felt; for although several books on trees and shrubs have appeared within the last twenty years, there has been no really standard work to compare with Loudon's "Encyclopædia of Trees and Shrubs," which was published between seventy and eighty years ago. The book under notice, however, fills that want, and it will doubtless have as long a reign as Loudon's work. No comparison can be made between the two works, for they are treated in an entirely different manner, the only point of resemblance being the thoroughness with which each author conducted his work.

The new book is the work of Mr. W. J. Bean, the Assistant-Curator of the Royal Botanic Gardens, Kew, who for many years has had personal charge of the fine tree and shrub collections in that establishment, and whose critical knowledge of everything connected with trees and shrubs is well known throughout the country. There are two volumes, the first containing 688 pages and the second 736 pages, and the book is divided into two parts. Part I. ends at page 110 of the first volume, and consists of short chapters on culture, trees and shrubs for various special objects, such as autumn colour, street planting, fine foliage, coloured bark, seaside planting, &c., and concludes with a glossary of botanical terms, which will be found useful to those who find a difficulty with such technicalities. The practical man will be pleased to find chapters upon such pertinent subjects as propagation, hybridising and selection, transplanting, soils, pruning, care of old trees, &c., while the first chapter, entitled "Historical Notes," is particularly interesting.

The second part of the book, however, which begins on page 111 and is continued to the end of the second volume, is the most important, and the more one reads of this part, the more one is impressed by the critical knowledge of the author and the care he has bestowed upon his work. The genera are arranged alphabetically, and in each case a general description of the genus is given; then the principal species are described separately, with any important varieties. The same plan pertains throughout the work, and, in the descriptions of the species, the scientific name with the authority for the name, followed by the common name, when there is one, heads the descriptive matter. Then come well-known synonyms, particularly where confusion is known to exist, and, when possible, a reference to a picture of the plant. The descriptive matter is then divided into two paragraphs, the first giving a botanical description of the species in simple and easily understood terms, and the latter giving its native country, date of introduction, behaviour under cultivation, special requirements and other interesting items.

The following description from Vol. I., page 499, gives a good idea of the working

* "Trees and Shrubs Hardy in the British Isles," by W. J. Bean, Assistant-Curator, Royal Botanic Gardens, Kew. Two vols.—Vol. I., pp. 1—688; Vol. II., pp. 1—736, including index, with numerous full-page and text illustrations. London: John Murray; price 42s. net.

plan: "*Disanthus cercidifolia*, Maximowicz. Hamamelidaceæ. (Sargent's Forest Flora of Japan, t. 15.) A deciduous shrub up to 8 or 10 ft. high, with slender, spreading branches; young shoots perfectly smooth and round, and marked with small whitish lenticels. Leaves alternate, firm, very broadly ovate to roundish, heart-shaped or truncate at the base, blunt and rounded at the apex; 2 to 4½ ins. long, and almost or quite as broad; perfectly smooth, glaucous green and entire; stalk 1 to 2 ins. long. Flowers dark purple, two of them set back to back at the end of a stalk ½ in. long, produced from the leaf axils. Each flower is ½ in. across, with five narrow tapering petals, arranged starwise; calyx with five short recurved lobes; stamens five. Seed-vessel a woody, nut-like capsule. Native of Japan; introduced about 1893, not yet well known in gardens. It has not yet flowered in Britain to my knowledge, and the appearance of the blooms is chiefly known from Sargent's figure above cited. We know it, however, to possess one excellent quality: its foliage, handsome and Judas-tree like in form, turns in autumn to one of the loveliest of claret-reds suffused with orange. No new shrub, indeed, is more beautiful in this respect. It is rather tender when young, but appears quite hardy after a few years. A plant at Kew, 3 ft. high, growing in peaty soil in a bed of heaths, is in excellent condition, and was not injured in the least in the winter of 1908-9. *Disanthus* (the name refers to the paired flowers) is only known by this species. It belongs to that group of the witch-hazel family with many seeds in each fruit. In Japan it flowers in October when the previous year's seeds are ripening, resembling in this respect its ally the Virginian witch-hazel."

From this description it will be seen that a person knowing nothing about the shrub is able to form a pretty accurate idea of its general character and peculiarities, and throughout the book the descriptions are given in the same lucid manner. The book throughout appears to be wonderfully free from errors, the one or two we have noted being of a trifling character and due evidently to the vagaries of the printer rather than to the author, such as the transposing of two letters in the word *Zanthoxylum* which heads page 690 in Vol. II. A considerable number of well-executed full-page photographs of specimen plants by Mr. E. J. Wallis are dispersed through the book, while upwards of 200 line drawings by Miss E. Goldring occur in the text, adding to the interest and value of the work. The book has been published by Mr. J. Murray, and the mechanical part, both as regards printing and finish, is good. We congratulate the author heartily upon the production of such a valuable work, which will be of the greatest use to all who have to do with trees and shrubs. The difficulties which have existed for so long regarding the correct names of certain trees and shrubs ought now to be set at rest, and we should like to see nurserymen and others accept Mr. Bean's decisions in the preparation of their catalogues and the naming of their collections. It is a book which should not alone find a place upon the shelves of every library of horticultural, sylvicultural and botanical works, but should be in constant use.

Sweet Peas and Antirrhinums.*—The author of this little book is undoubtedly one of the best

known men in the Sweet Pea world, and we have often thought that if he could be induced to write on the subject, something of more than usual interest would result. We are glad to find that our anticipations have been realised. Judging by the preface, Mr. Cuthbertson had some doubt as to there being room for another book on Sweet Peas; but this doubt having been appeased, he set to work in right good style. As anyone who knows him would expect, the book is, before all else, practical, and in this direction affords a welcome change from the twaddle that journalists inexperienced in matters pertaining to gardening have seen fit to put into print during recent years. Knowing the wonderful store of historical knowledge that Mr. Cuthbertson possesses, we would have liked to have seen a little more of this, especially in relation to the *Antirrhinum*. We congratulate him on placing the chapter on Sweet Pea culture for the average man before that dealing with the exhibitor. In these days of craze for size, too many authors and, we fear, floral enthusiasts almost overlook the man or woman who grows flowers for the love of them and who cares little or nothing for exhibition blooms. Doubtless his lists of the best varieties for different purposes will cause some heart-burning, but on the whole we consider them good and fairly compiled. The chapters on seed-growing and raising new varieties are, we think, the best in the book; but here again, like Oliver Twist, we would have preferred more, as few persons have given these subjects more attention than the author. Mr. Cuthbertson's faith in the future of the *Antirrhinum* is not misplaced. Anyone who has observed the wonderful improvements that have been made, especially in the colours of the flowers, during recent years cannot help thinking that this useful plant deserves far more attention from the gardening public than it at present receives. The plants are easily raised from seeds, and a good strain now will give seedlings practically true to colour. Another point in favour of the *Antirrhinum* is that up to the present it has not been subject to any serious disease, though in America we believe a species of rust fungus causes considerable trouble. The book is well printed and the illustrations are, on the whole, excellent.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

THE GREENHOUSE.

NERINE FOTHERGILLII NOT FLOWERING (Mrs. E. A. F.).—The cultural directions followed by you have been in the main correct. This is, indeed, shown by the large size and flourishing condition of the bulbs. The one point in which you have erred is in giving the bulbs water before the tips of the flower-spikes showed themselves. As soon as they can be seen, then water may be safely given, but if the plants are watered too soon, leaves, not flower-spikes, are the principal result. One other matter

is that we should certainly advise you to give less liquid manure during the growing season, say, once every fourth watering. By attending to these two points you may reasonably anticipate a good display of flowers next autumn.

CLEMATISES IN GREENHOUSE (G. B. Sykes).—It is quite possible to produce fertile seeds of Clematis in an unheated greenhouse, and no beneficial results would follow artificial heating with an oil stove. Keep the house well ventilated, but do not expose the plants to cold draughts, especially while the growth is very tender. To cross-fertilise the flowers, remove the stamens from certain flowers before the pollen is ripe, and enclose each emasculated flower in a light canvas bag. When the stigmata are ripe, transfer pollen to them, from the variety you wish to use for the male parent, by means of a small camel-hair brush. A sunny morning is the best time for the work. We do not know of any book upon the cross-fertilisation of the Clematis, but the work is quite easy.

TREATMENT OF PELARGONIUMS (*Pelargonium*).—Your suggestions for the treatment of your Zonal Pelargoniums are in the main correct, though exception may be taken to one or two items therein. In the first place, we think that cutting your old plants back to 2 inches or 3 inches is rather too drastic a measure, and would prefer to leave them from 3 inches to 4 inches in height. When cut back and placed in a rather warmer structure, the soil must be kept fairly dry till the young shoots make their appearance, as, if too moist, the plants will break out in an irregular manner. When the young shoots are about half an inch long is a good time to repot the plants. As much of the old soil should be taken away as can be done without unduly distressing the plants. The most suitable compost consists mainly of good loam, lightened by a little thoroughly decayed leaf-mould and sand. It is not to the advantage of these Pelargoniums to put them into pots too large; therefore we advise you that those you speak of as being in 48's would be better put into 32's than in 24's. Some varieties grow more vigorously than others, and it is quite possible that by, say, the end of April you would feel justified in shifting some of the largest into 24-sized pots. The plants must, of course, be kept in a good light position, and any shoots that show a tendency to run away should be stopped. This ought not to be done for a couple of months before the plants are required to be in flower. You will be quite right in removing the flower-buds up to six weeks before the plants are required to be at their best. In the case of the cut-down plants, it is quite probable that you will find pots of the size they are now in will be quite large enough. In this case they will be benefited by a shift into larger ones, say, about the end of April. In potting, the soil should be pressed down firmly, as loose soil leads to rank growth and, consequently, more irregular-shaped plants with fewer flowers. Stimulants should not be given till the pots are well furnished with roots, and even then an excess must be avoided. A couple of months before the plants are required to be at their best is a very suitable time to feed them. This may be given in the shape of liquid manure and soot-water combined, or one of the many plant foods now obtainable. Some of these last being very powerful, they must not be given stronger than the furnished instructions. In any case, once a week is a very suitable time to give these stimulants. Plenty of light and air is very necessary for the successful culture of the different forms of Pelargonium. Regal Pelargoniums.—The end of July is certainly rather late to have Regal Pelargoniums at their best. A good deal may, however, be done by following a systematic course of treatment, though even then you can scarcely expect them to be as good as they would be, say, six weeks earlier. It will be a good plan to put the plants that need a shift into larger pots. The growing points, too, may be pinched out in order to induce the formation of secondary shoots, but this should not be done later than two months before they are required to flower. The buds may be picked off up to six weeks beforehand, but on this point a little discrimination must be used, as a spell of dull, cold weather may cause the blossoms to stand still, or nearly so. In that case it is better to have the flowers in bloom a little too early than too late. Your application for the rust may have been a little too strong. The same instructions as to potting, compost, air, &c., will apply as those directed for the Zonal Pelargoniums. If your plants are intended for a show, you will find it a great advantage to gum the flowers before moving them about, as the petals so readily drop. Florists' gum can be readily obtained from the horticultural sundriesmen, and a tiny drop in the centre of the flower will go far to prevent the premature dropping of the petals.

ROSE GARDEN.

TONK'S ROSE MANURE (E. S. M.).—This compound is not offered for sale, so far as we know, but any good firm, such as Messrs. V. Voss and Co., Carlton Works, Millwall, would make it up for you. The recipe is as follows: Superphosphate of lime, twelve parts; nitrate of potash, ten parts; sulphate of magnesia, two parts; sulphate of iron, one part; and sulphate of lime, eight parts. Apply it this month, a quarter of a pound to the square yard of surface. The climbing Roses in the greenhouse should be pruned after flowering, say, about May. They would then have the summer to make new growths, which are retained almost full length to flower the following spring. If the long growths have side shoots or laterals, you can prune these now to about three eyes from their base, but retain the long rods made last year nearly their full length.

* "Sweet Peas and Antirrhinums," by William Cuthbertson; price 1s. net. London: Messrs. James Clarke and Co., 13 and 14, Fleet Street, E.C.

THE GARDEN.

No. 2258.—VOL. LXXIX.

FEBRUARY 27, 1915.

NOTES OF THE WEEK.

A Handsome Hazel.—Few prettier sights are to be seen in early spring than good specimens of the Hazel when well laden with male catkins. This year in many places they are making a fine display. A shrub worthy of more attention for its ornamental qualities is the Constantinople Hazel (*Corylus Columna*), which forms a tree and bears longer catkins than the common kind. When in fruit the peculiarly cut calyx, which most covers the nut, is also very interesting.

Ivy for Covering Damp Walls.—There are many uses to which the Ivy may be put, and in a number of cases it has no equal, one of these being for covering a damp wall. An instance we have in mind is a wall of a dwelling-house which at one time suffered very much from damp. On our advice Ivies were planted to grow up the wall, and we understand now that it is well covered and that very little evidence of damp is seen. This is undoubtedly known to many, but it may be a useful hint to some of our readers, as Ivy can be successfully planted at this season.

Winter Aconites and Snowdrops.—These are very pretty at the present time, in some places grown separately and in others as a mixture. They are used in some instances to carpet ground beneath shrubs, and are particularly attractive when planted in broad masses. In some places they are used beneath beds of red-barked shrubs, such as *Cornus alba*, and the contrast is very effective. Both Winter Aconites and Snowdrops may be expected to give better results when planted in cultivated or semi-cultivated land than when planted in close grass, for they cannot adapt themselves to close turf with the same facility as the Crocus; therefore, when groundwork is wanted for beds or borders of deciduous shrubs, they should be remembered.

The Japanese Witch Hazel.—The difference between *Hamamelis japonica zuccariniana* and other Witch Hazels is most apparent in the colour of the flowers, for instead of the familiar golden hue, the blossoms are in this case a clear pale cream. A native of Japan, it forms a large bush or small tree in its native country. Here we are familiar with it as a wide-spreading bush, at least six feet or eight feet high, with rather slender branches, from which a profusion of flowers with narrow, curiously twisted petals appear during

late January and early February. It cannot be depended upon to come true from seeds, and is usually grafted upon stocks of *H. virginiana*. When planted in light, loamy soil containing a little peat, it grows rapidly and forms a shapely bush with little or no pruning.

Pernetiana Roses.—At a Council meeting of the National Rose Society, held last week, it was definitely decided to adapt the prefix "Pernetiana" to the group of Roses characterised by Rayon d'Or and Arthur R. Goodwin. Although this name is not botanically correct, it has been so universally adopted that it was considered by the majority of the members of the Council inadvisable to alter it. We suggest that the botanical difficulty could

pass on the hint for the benefit of any readers who may have these plants at their disposal. Even without the Ferns the two colours would be charming.

The Perpetual-Flowering Carnation Society.

—We understand that the above Society has just completed arrangements with the North of England Horticultural Society for holding an exhibition at the Corn Exchange, Leeds, on April 29 and 30. The schedule will be published shortly.

Preserving Cut Flowers.—The results of numerous experiments conducted at the Cornell University, U.S.A., show that there is no better method of preserving cut flowers yet known than cutting a short piece off the stem each day. A number of chemicals, dissolved in the water, were tested, but the results were not such as to justify their recommendation.

The Kashmir Primula.—Before many weeks are over, the beautiful Primula illustrated on this page will be opening its globe-like heads of violet flowers. Although classed by the Kew authorities as a variety of *Primula denticulata*, it is regarded by many as a distinct species. It is a charming plant for a moist spot in the rock garden, but shade is not a necessity. The under surface of the foliage is coated with farina. Soil that consists of good loam and a little rough peat seems to suit this Primula, which certainly deserves to be better known than it is at present.

Outdoor Crocuses for Bowls.

—Owing to the wet, cold and windy weather, the early Crocuses, such as *Sieberi* and *biflorus*, have presented

a very dejected appearance outdoors this year. To enjoy their full beauty we have lifted some good clusters, put them into glazed bowls filled with sand, and taken them indoors. There the flowers quickly expand, and reveal the beautiful orange stigmata and internal colours of the perianth segments. The plants should be lifted with roots and soil intact, placed in the bowls, and the spaces between filled with dry sand, ordinary builder's sand or silver sand answering equally well. This is then thoroughly soaked with water and the surface covered with a little green moss to give the whole a neat appearance. Treated in this way Crocuses will last in good condition for nearly, or quite, a fortnight.

A WELL-FLOWERED PLANT OF THE KASHMIR PRIMULA
(*P. DENTICULATA CASHMERIANA*).

have been eliminated by calling this class Pernet Roses, in the same way as we refer to the Noisette group.

A Charming Colour Arrangement of Greenhouse Flowers.—When inspecting the private conservatory of a partner of one of our leading seed firms last week, we were particularly pleased with a simple grouping of flowers. At the far end of the conservatory Maidenhair and other Ferns had been arranged to form a steep bank, two fairly large spaces towards the centre being left for flowering plants. These were filled with blue *Primula obconica* and the yellow *P. kewensis*, the twain being lightly intermingled. The effect was so quiet and good that we

HOME-GROWN VEGETABLES AND OUR FOOD SUPPLY.

Our article and the subsequent letters on the above subject have created considerable interest among horticultural societies, and we give a selection of letters from those who have already adopted our suggestion, or intend to do so. We take this opportunity of once more pointing out that the object of our article was mainly to increase our home supplies of food, the disposal of any surplus produce being a secondary matter. We shall be pleased to send reprints of the article to any secretary of a horticultural society for distribution among his members.

I MYSELF am fully in sympathy with the work, and you can take it my society will be. Last August I wrote, through the medium of the local Press, urging the cultivation of every available plot of land, large and small. In November we also held a special patriotic show, and raised a clear profit of £142 for the National Relief Fund. We have already decided to go forward with our exhibition as usual, on July 16 and 17; in fact, our schedule of sixty-eight pages will be out next week. I wish the movement every success, and assure you of my whole-hearted interest and co-operation.

WILLIAM G. CARRADINE.
Birmingham Horticultural Society.

THE doings of our horticultural society have perforce to be indefinitely postponed during the war; but I for one—and others on the committee—have strong ideas of the desirability of wakening everybody to the desirability of increasing our vegetable supplies. By precept and example I hope to continue the crusade, trusting that others may also rise to the importance of the same. I hope your article may increase enthusiasm on the subject.

LILIAN JONES BATEMAN, Hon. Secretary.
Abergele Horticultural Society.

I SHALL be pleased to place the article on vegetables before my committee. They are thinking of withholding all prize money in gardeners' classes, and, after deducting bare working expenses, to present all surplus money to the Belgium Restoration Fund. I will certainly do all in my power to get members to send any vegetables they may have to spare to some institution.

C. E. BROOKER, Secretary.
Highgate Horticultural Society.

IN reference to the important question of our national food supply, I may say we have had this question under consideration, and have already adopted a system for sending a monthly supply of fruit and vegetables to the Fleet at some naval base. Our president and myself have been appointed as a local committee (Norwich branch), and we have appealed to all our members, as well as to those of the affiliated Norfolk and Norwich Horticultural Society, and also to the Norfolk public, through the Press for their co-operation and support. All contributions are received at my office address monthly, whence I have already sent away two good representative consignments, which have been gratefully acknowledged. It is our intention to maintain a monthly supply throughout the summer if possible, and trust that our efforts will meet with success.

W. L. WALLIS, Secretary.
East Anglian Horticultural Club.

I READ your article *re* increasing our vegetable supplies before the members at our last meeting. Time would not allow a good discussion upon the

subject, but as it was sent to the committee for them to consider it, we shall have a special meeting next week for this purpose. If in the meantime any further suggestions are offered by your readers, will you let me know, and I will forward to you any information I can gather upon the matter. The enclosed circular *re* Croydon Vacant Lands Cultivation Society may interest you. This is a separate body to our society, but part of the committee is composed of members from our society. A considerable amount of vacant land is now under cultivation.

HARRY BOSHIER, Hon. Secretary.
Croydon and District Horticultural Mutual Improvement Society.

[Judging by the circular sent by Mr. Boshier, the Croydon Vacant Lands Cultivation Society is doing good work in securing vacant plots and getting them under cultivation by working men.—ED.]

OUR society is in sympathy with your good move, and we wish you success in your work for a good cause. Our committee do not see their way clear to offer any products just now, but if any be needed during the summer months, perhaps we shall be better able to do it then. I may state that we are situated in a colliery district, and it is hard work here to cultivate our own produce. *Re* growing and assisting others to cultivate their gardens, we have already done good work in this way, and are still doing good work in encouraging cottagers to cultivate their plots of ground. We intend to hold a show on August 19, and all the proceeds will be devoted to the proposed new cottage hospital in this locality. We are affiliated to the Royal Horticultural Society and hold weekly lectures on horticulture free of charge, when there is a very good attendance. Our last lecture was on the Brassica family, the lecturer being Mr. W. Payne. He urged us to grow Cabbage, Cauliflower, Brussels Sprouts, &c., because one or the other is available all the year round.

T. M. LLOYD, Secretary.
Aberaman Horticultural Society.

IN reference to growing more vegetables, I would tell you some of our work as a horticultural society in this district. After many years of struggle, we have secured nearly thirteen acres of land, which we let to our members as allotments, ranging from five to twenty rods of ground each, so as to spread it among as many as possible. We have 177 working these plots. All are keen, and every plot is let. We discourage the growing of flowers on these by refusing to allow flowers grown on allotments to be exhibited at our shows. I may say we have a full programme, as usual, this year, our motto being "Carry On." Regarding your note on the supply of seeds, one of our committee drafted a collection suitable to our members' needs and submitted this to a reputable firm of seedsmen, and asked them to supply these collections at a fair and low price. The firm did so, and our members have the seeds. We have lectures and

discussions at the beginning and waning of the seasons, so that our members may gain knowledge and also begin necessary operations at the right time. We try to embrace every branch of horticulture in our schedule. In the economic section we have over forty classes this year at our summer and autumn shows, also classes for home preserves. The matter of surplus vegetables we have fully discussed, and you will readily understand that, with the small plots our members have, there will not be much left after their own family needs are catered for; if there are any, we shall, no doubt, find some way of collecting them and sending what we can where they are needed. But you will, no doubt, agree with us when I say we consider we are doing good work by encouraging our members to keep their own families supplied first. Of course, we feel things tight this year, but I have had so much encouragement already that I face the work very hopefully now. I trust you will excuse my lengthy epistle, but I wished to show you we are alive and have anticipated the ideas expressed in your article, and have dealt with every phase of it to the best of our ability. When I tell you our work is all done in the evenings, you will realise the result is not unsatisfactory.

H. A. BEECROFT, Hon. Secretary.
Seven Kings and Goodmayes Horticultural Society.

IN reference to your article on "Home-grown Vegetables and Our Food Supply," I think the ideas advanced are excellent, and I will endeavour to get the societies connected with our association to do what they can in regard to the matter. We hope to hold our show on August 25 and 26.

H. DUNKIN.
Warwickshire Horticultural Association.

YOU may be interested to hear that the Birmingham Horticultural Society have applied, through Mr. William G. Carradine, their secretary, for a grant of our small booklets on "Cropping Allotments" for the use of their members. I have sent them five dozen. You will be interested to know that your article on "Home-grown Vegetables and Our Food Supply" has evidently attracted attention in quarters where you would desire it.

EDWARD OWEN GREENING.
The Agricultural and Horticultural Association, Limited.

I WAS very pleased indeed to see the excellent letter from Dr. Lillias Hamilton in your last issue. The most important point raised by her is, I think, that more root crops should be grown this year than usual. Undoubtedly Potatoes, Onions or Carrots will produce more valuable food from a given area than Cabbages or Cauliflowers, wholesome and useful though these are. Co-operative piggeries for allotments ought certainly to be widely adopted. Apart from eating up refuse, pigs provide a particularly valuable garden manure.

ANOTHER F.R.H.S.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Helxine Solierolii as a Carpeting Plant.—I do not think this very useful carpenter is as well known as it should be. It grows, to quote Mr. Farrer, "as quick as a dream or a fungus." It has the reputation of being not quite hardy; but here in Birmingham, where the climate is anything but genial, I find it will stand any amount of frost, provided it is kept dry from November to March with a pane of glass placed an inch or so above it. It is in the moraine and is also spreading itself all over the path, and is a beautiful bright green all the year round. I find it more satisfactory than *Arenaria balearica*, which here is apt to die off. Another advantage is that every scrap broken off will grow.—H. E. I.

Shows, Schedules and Judges.—Having had a rather lengthy experience both in the framing of prize schedules and in judging, I feel interested in the discussion in THE GARDEN on the above subjects, and would like to draw attention to a common mistake made by judges, either through lack of thought or through lack of moral courage. I refer to the failure to withhold a prize or to make a modified award in the case of an inferior exhibit, when only one exhibit, and that of inferior quality, is staged in a given class. A first prize is often awarded as a matter of course, thus giving the public an erroneous impression as to what is the ideal standard of excellence with regard to the subject for which prizes are offered. On the same principle, two exhibits are staged in a class, the one of great merit, the other greatly inferior; but they are awarded first and second prize respectively. In my opinion, "these things ought not so to be."—CALEDONIA.

The Purple-Flowered Cistus.—There is no doubt that *Cistus purpureus* is the finest of its colour, although one often meets with many inferior plants under that name. By some it is regarded as a native of the Levant, while other authorities recognise it as a hybrid between *Cistus ladaniferus* × *C. villosus*, and there seems reason to believe that the latter is undoubtedly its true origin, for no specimen has ever been known to be collected wild, while it gets its colour from *C. villosus* and its size and spots from *C. ladaniferus*. It is of a spreading habit, about four feet high, and often more through, with dark green, oblong, slightly rugose foliage. The flowers, which are quite 3 inches broad, are terminal, generally in threes, and are lilac purple in colour, while near the base of the petals the beauty of the flower is enhanced by a large ruby red spot, which makes it so distinct and ornamental, and in striking contrast to the bright yellow stamens. The *Cistus*es are among the showiest of ornamental flowering shrubs, blooming for a considerable part of the summer, and should be included among any that are being planted. They are excellent for sunny positions in light soil, often thriving in poor ground where many other shrubs would fail.—F. G. PRESTON.

The Ideal Daffodil Catalogue.—May I crave a little of your space for comment on the Rev. J. Jacob's "Daffodil Notes" in your issue of January 30, as far as they deal with my previous remarks on Daffodil catalogues? Mr. Jacob's notes are always interesting, but he must pardon me if I confess to finding them in this instance less relevant than usual. The point of my remarks

lay in the contention that in the best Daffodil catalogue known to me, certain marks of excellence have been awarded to the several varieties (four crosses to the best quality, three to the second-rate, and so on), and that the excellence thus indicated is, roughly speaking, in proportion to the price; in other words, that, when a variety sinks to a moderate price, it becomes, *ipso facto*, second-rate. In support of this contention I gave certain figures and averages from the Pimlico catalogue. Mr. Jacob says nothing to controvert this, though no doubt he can guess shrewdly enough what catalogue was in my mind. (I might say, however, that my figures were taken from the 1913 catalogue and not from that for 1914, which was not then to hand.) As to high-art adjectives, if bulb merchants choose to use these to excess, there is no statute to prevent them, and dictionaries are cheap. The only fear is that they may exhaust the language and get gravelled for lack of high-flutin epithets. By the way, a certain Irish firm

Good in grass, pots, beds, and vases—2s. per doz. Mrs. R. Sydenham (Ajax).—This is one of the best recently introduced white self-coloured Daffodils, of perfect form and great substance; perianth broad, firm, and pure white; pure white narrow trumpet beautifully recurved at mouth; still, in our opinion, unsurpassed as a white trumpet. A.M., R.H.S. Good in beds, pots and vases—12s. 6d. per bulb. Alannah (*Triandrus Hybrid*).—A lovely self lemon colour, short trumpet, beautifully crested at mouth, with very level perianth; a very beautiful flower—£30 per bulb." The trail of the serpent is perhaps traceable even in Doe and Roe, but, at any rate, their catalogue does not pay to mere costliness the homage paid by some firms. If I might make a suggestion (which I do with diffidence), it is that a certain economy should be practised in the expenditure of epithets, in respect at least of a flower which "needs no bush." That comprehensive word "precious," which conveys all that there is of

THE PURPLE-FLOWERED ROCK ROSE (*CISTUS PURPUREUS*).

(the well-known Messrs. Doe, Roe and Co. of Dublin) distributes a Daffodil catalogue which bids fair presently to come within measurable distance of the 'ideal catalogue. In point of scientific arrangement and "get-up" it is not equal to that of the Pimlico firm; but its intention is excellent, and the information it gives, if less ecstatic, is fuller and more serviceable, though, so far, not so full and serviceable as it might be. I extract from this Dublin catalogue two or three paragraphs, in the ambitious hope of convincing Mr. Jacob that the perfect catalogue, when it arrives, need not be cold, and, what is perhaps equally desirable, that it may achieve its purpose without bringing the English language to bankruptcy. It must not be forgotten that in listing Daffodils a correct classification is in itself descriptive—half the battle, indeed. This is how Doe and Roe proceed: "Albatross (*Burbidgei*).—A beautiful flower, with large spreading white perianth, and pale citron-yellow cup, edged bright orange scarlet; very floriferous; one of the best. F.C.C., R.H.S.

"too-tooishness," might be reserved for flowers costing, say, from £5 to £50 per bulb; so that, if a variety were described as "precious," we should know that it was a flower of surpassing loveliness and cost a minimum of £5. The baldest and most pedestrian prose available would be used for such flowers as cost a beggarly 30s. or less. The middle zone (between 30s. and £5) might be reserved as a Daffodil limbo or purgatory, where flowers on the down-grade might linger till such time as they became cheap enough to be finally d—mn—d.—SOMERSET.

FORTHCOMING EVENTS.

March 2.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1 p.m. to 6 p.m. Lecture at 3 p.m. by Dr. Claud F. Fothergill on "Pressing Flowers to Retain Their Colours"; and by Colonel Rawson, C.B., on "Colour Changes in Flowers by the Removal of Sunlight." Royal Horticultural Hall, Vincent Square, Westminster.

THE EARLY HISTORY OF LILIUM TESTACEUM.

THIS beautiful and distinct Lily, which is referred to by Sir Herbert Maxwell, Bart., on page 64, as one of the loveliest of the race, is, as stated by the writer, of unknown origin. Concerning its early history, the most complete account that has come under my notice occurs in a book of 122 pages, entitled "Monographie, Historique et Littéraire des Lis, par Fr. de Cannart d'Hamale, Président de la fédération des Sociétés d'Horticulture de Belgique, &c.," printed at Malines, 1870. Somewhat curtailed and rather freely translated, it reads as follows:

"There is also another Lily, with recurved petals, concerning the origin of which we have but a vague idea, but which, nevertheless, appears to be Japanese, viz., *Lilium testaceum* of Lindley (the Nankeen Lily). It was first discovered by M. Fr. Ad. Haage, jun., of Erfurt, accidentally, in a large consignment of Martagons which he had received from Holland in 1836, and with which it had been mixed. The plant was introduced into Belgium by L. van Houtte of Ghent, who had received a case full of it from M. von Weissenborn of Erfurt in exchange for some Fuchsias. This exchange was made in 1840 or 1841, at which time there is no question that of this unknown Lily three persons of Lille in France each possessed an offset. One only of these offsets chanced to flower, at Esquermes-lez-Lille, and showed an umbel of pendant blossoms, with petals reflexed like the Martagons, but larger and of a beautiful nankeen colour, slightly tinged with rose, and dotted with a deeper tint at the base. The bright orange-coloured stamens served to add to the beauty of the flower.

"M. van Houtte, who happened to be at Lille, was fortunate enough to see this splendid novelty. He eventually received from M. von Weissenborn an order for Fuchsias, with a postscript in the following terms: 'If by any chance you want the nankeen-coloured Lily, I have a quantity at your service.' M. van Houtte did not think twice about it, and seized with avidity the good fortune offered to him. He accepted the exchange, and soon became the possessor of a case more than a yard square full of Nankeen Lilies of all sizes, the largest bulbs measuring more than a foot in circumference.

"This news soon spread to Lille, and there caused much talk and great disappointment when the possessors of the three offsets were convinced that the Lily of which M. van Houtte had become the owner was the same as those which they guarded so jealously. The Nankeen Lily passed from Belgium to England, where it flowered for the first time with Messrs. Rollisson. It was figured and described in the *Botanical Register* by Dr. Lindley in 1843, under the name of *Lilium testaceum*. Dr. Kimtze of Halle had described it as *L. isabellinum*, and it also bore the name

of *L. excelsum* among gardeners. M. Rinz, sen., a nurseryman at Frankfort, and another gardener at Leipzig claimed to recognise in it an old friend which they had cultivated in their younger days. This was evidently a mistake, for no mention of this Lily has been made in any work on botany or horticulture. We are more inclined to believe that it is of recent introduction, and that the Dutch received it from Japan, with which country they were in constant communication. But is it really a true species? Or is it not rather the product of the white Lily fertilised by one of the *Pomponium* section? The general appearance of the plant would lead one to suppose so."

As the foregoing was written within a reasonable distance of the time that *L. testaceum* made its first appearance, information on many points

PLANTS FOR OLD MASONRY WALLS.

THE clothing of old walls with vegetation of a varied and more or less pleasing character is a phase of gardening which is being more widely adopted each year. When successful, a wall thus treated should prove a source of great enjoyment to its owner and possess the additional merit of costing very little to maintain. Where dry walls have been specially built with a view to providing a congenial home for plants that naturally appreciate a more or less dry and elevated position, the process of evolving a pleasing array of flowers and foliage is much simplified, and as such walls have previously been dealt with, it is not proposed to give more than a passing word to them now.

It is in relation to the clothing of those old masonry walls which exist in so many gardens that information is often sought after, and it is here that the ingenuity of the gardener needs to be exercised to the utmost limit. Such old walls may be roughly divided into two sections, i.e., retaining walls and those which have both sides more or less fully exposed to the elements. It is in the first-named set that we find the best home for our flowers; but those of the latter section, particularly on the sunny side, may be made attractive by the application of a reasonable amount of intelligent and unremitting care.

As in most other phases of gardening, the success or otherwise of our efforts to establish plants on walls of this description depends not a little on what may be termed the spadework, consisting actually of the free use of a cold chisel and a hammer of substantial proportions. There is no doubt that the best way to establish plants in a masonry wall is to follow the dictates of Nature, and instead of attempting to introduce large plants of flabby character, to rely on very small seedlings, or, better still, the seeds themselves. While some successful wall gardeners declare the autumn to be the best season for sowing seeds or introducing seedlings, others are equally emphatic in advocating March or April as the best time in which to do the work; and, all

things considered, there is rather more to be said in favour of the latter period than the former.

To return to the preparation of the wall. This must be seen to without delay if seeds are to be sown this spring, as the earlier they are in now, the better. In the case of a retaining wall, the top usually forms a suitable ledge for several inches of soil, in which a number of plants may be grown that would scarcely thrive in the crevices between the bricks or stones. It is in the making and filling of these crevices that some care needs to be exercised. A long cold chisel, driven home with a heavy hammer, will, in most instances, quickly clear out sufficient of the mortar to allow a moderate packing with soil, and in some cases it may be possible to dislodge a small portion of

THE AMERICAN FRINGE TREE (*CHIONANTHUS VIRGINICA*) AS A POT PLANT.

would be more readily obtained than at the present day—forty-five years later. H. P.

THE FRINGE TREE AS A POT PLANT.

THE illustration on this page suggests what a charming subject for ornamental pots we have in the little-known Fringe Tree (*Chionanthus virginica*). This shrub or small tree is a native of the Eastern United States, and in the open forms a bush up to 10 feet in height, its flowers being produced at the end of May or early in June. The blossoms are white, feathery, and very fragrant. It will grow well in good loamy soil, and deserves to be much more widely known.

brick or stone without endangering the safety of the wall. All the crevices should slope downwards to some extent, so that any moisture which collects on the side of the wall may have an opportunity of reaching the roots of the plants. The best soil for filling such crevices is good turfy loam and chopped sphagnum moss, the latter being added for the sake of its moisture-retaining properties. This mixture must be rammed well into the crevices, a few small pieces of brick and stone being wedged in afterwards to prevent it being washed out. If these can be allowed to project slightly, and made to slope inwards and downwards, they will assist considerably in collecting moisture for the seedlings in the earliest and most critical stages of their career.

The actual sowing of the seeds may be done in various ways, but the most practical is to roll a few seeds into a small ball of similar soil to that used for filling the crevices, and thrust this well into the packed cracks. There is little danger of seeds sown in this way being blown out by wind. If seedlings are used, they must be planted in the crevices at a very early stage of their career. If possible, a heavy syringing of the wall late in the afternoons of bright days will assist the seedlings to become well established before the autumn. The clothing of masonry walls with plants is of necessity a slow procedure, and one that calls for a certain amount of patience on the part of the owner.

The following are plants that may be sown at the present time on walls of the description mentioned, and although some failures are almost certain to occur, sufficient success should be secured to induce the cultivator to sow more another year: For tops of retaining walls—Pentstemons, Wallflowers, Antirrhinums, Thrift, such Pinks as *Dianthus fimbriatus*, **alpinus*, **arenarius*, **cæsius*, **Caryophyllus*, **cruentus*, *deltoides*, **suavis* and *sylvestris*; Alpine Poppies, *Aubrietias*, *Arabis alpina*, *Corydalis lutea*, *Alyssum*, *Lychnis Lagascæ*, *Campanula rotundifolia*, Foxgloves, *Honesty*, *Linaria alpina*, **L. Cymbalaria*, *Drabas* of various kinds, **Erinus* in variety, *Saponaria ocyroides*, *Gypsophila cerastioides*, *Sedums anglica*, *acre*, *dasyphyllum*, *rupestris* and *grandiflora*. In addition to those above which are marked with an asterisk, the following are suitable for the sunny, or partly sunny, side of a wall: Any of the *Encrusted Saxifragas*, of which seed can be obtained; *Campanula muralis*, *C. pulla*, *C. garganica*, *C. cæspitosa*, *C. pumila* and *Arenaria cæspitosa*. For the shaded, or partly shaded, side: *Linaria Cymbalaria*, such Mossy *Saxifragas* as *sancta*, *Elizabethæ*, *juniperifolia* and the *Campanulas* named above as suitable for the sunny side. The *Sedums* mentioned for the top of retaining walls are best installed by sowing the fleshy leaves. These should be pulled or shaken off the stems, mixed with fine potting soil and placed in the positions it is intended the plants should occupy. There are, no doubt, many other plants that could be induced to thrive on old masonry walls, and not a little of the interest and pleasure derived from this form of gardening is obtained by experimenting with likely subjects.

In the crevices of dry walls practically all the plants named as suitable for the tops of retaining masonry walls could be grown, as there would, of course, be sufficient soil and moisture present to enable them to thrive. As previously stated, a dry wall possesses far greater possibilities than a loaded one.

H.

A CHARMING WINTER FLOWER.

CYCLAMEN COUM.

DESPITE their attractive flowers and the fact that many of the species bloom at a very welcome time of the year, the hardy *Cyclamen* do not appear to be grown (especially in the small garden) to nearly the extent that their beauty justifies. The accompanying illustration of a group of *Cyclamen* grown by Messrs. Piper shows how decorative a colony of *C. Coum* can be with its

SEASONABLE NOTES ON CARNATIONS.

Winter Flowers.—Though there has been abundance of bloom on Carnations, even in the depth of winter, the flowers have been smaller than usual, not improbably on account of the almost entire absence of sunshine for weeks on end; but there also may be a contributing cause in the abnormal freedom from frost, permitting the almost total dispensing with artificial heat and giving the plants less air. About the middle of January all the plants were surface-dressed with artificial manures, and with the lengthening days there is to be seen a decided improvement in the flowers.

About Novelties.—For a time I was dubious whether the much-praised novelties of last

A BEAUTIFUL COLONY OF CYCLAMEN COUM, A CHARMING WINTER AND EARLY SPRING FLOWER.

rich-coloured flowers (and also its white or pale pink form) when they come to gladden us in February, rising but 2 inches or 3 inches in height above the deep bronzy green foliage devoid of marbling (which characterises many of the other species). The under sides of the leaves, too, are of a rich bronzy crimson tone. The best cultural conditions appear to be half or three-quarter shade, extremely gritty humus, with copious drainage, and an absence of disturbance. At the base of some large tree where the soil is light, poor and more or less dry, the *Cyclamen* seem to thrive amazingly, while, if beds are prepared for them in the rock garden—perhaps at the base of some large sheltering stone—where the soil consists of half stone rubble, with sand, leaf-mould, fibrous loam and old mortar in about equal proportions, they will do quite well, and make a delightful picture in the early spring.

REGINALD A. MALBY.

spring were likely to be of value. Now it is clear that *Champion* is a glorious colour, but I am afraid the plant may prove less healthy than some of the more vigorous sorts—*Triumph*, for instance. I care less for *Gorgeous*, though this, too, is a great acquisition, and it would be none the less so were it less tall in habit. *Champion* is likely to run *Mary Allwood* very close for supremacy, and it is likely to be a case of the old song, "Were t'other dear charmer away." A few plants of *Mary Allwood* have produced very "washy" flowers, so different from the true form that it is curious how they should be so much unlike. The unreliability of Carnations is, of course, well known, but I have never seen any go quite so far astray as this. Last year we had one or two plants of *Mikado* which produced much-improved flowers, and of *Rose Doré*, always good in colour, there was one plant which gave us blooms of the most entrancing loveliness. *St. Nicholas* is

generally reckoned a little less good than it might be. At the same time, it has always proved itself here to be a reliable winter bloomer, and in the open in summer there is none better. It has a nasty habit of breaking badly in spring, and more than once I have found it necessary to pinch out the one or two breaks in order to force the back buds to come away.

The Rooting of Cuttings.—Last autumn some cuttings rooted in a shorter space of time than I previously had noted. It is usually not difficult for the experienced eye to distinguish a cutting which is making roots. Eight days after inserting a batch I noticed in a few that roots were being formed, and on raising them found it to be the case. Frequently I have known roots to be produced in ten or eleven days; but this is the shortest period in my experience. I wonder if any of your correspondents have noticed such rapid production of roots.

One Year Old Plants.—The exigencies of labour arising from the war have made it impossible to grow as many plants as usual, and a portion of one year old plants will shortly be set aside to supplement those recently propagated. It is customary to grow on a few thus every year, especially of the better novelties, and it is well known that Carola gives the best results in the second year; but these are merely given a larger-sized pot, to provide the needed nourishment. Many of our plants are already in pots large enough to carry them on through another year, and it is a moot point whether it would be better to give nourishment by periodical applications of manure or to reduce the ball and repot in receptacles of the same dimensions. My own feeling is that with the majority of plants the first-mentioned method is quite equal to the demands of the plants, the danger of reducing the ball being a loss of foliage owing to drying before new roots could be formed. In most plants this would not occur, but with the Carnation it has to be reckoned with. Only those plants which can be reduced considerably in height are of use for a second year's production, and with this in view I have been removing all side shoots well up the stems as they appear, and encouraging the lower ones to strengthen themselves.

There is nothing to be gained in stopping the last named before they become fairly strong, even though it seems a waste of time and of vegetable vigour. When stopping does take place, once the stems have become fairly firm they must be pinched well back, say, to the lower eight leaves. Stopping of young plants should be effected on the same principle. If it is essential that a plant should be allowed to make twenty leaves before being stopped, not more than six or eight should be left after stopping. The shoots forced to break will invariably be stronger.

R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

THE DELPHINIUMS OR PERENNIAL LARKSPURS.

FOR creating bold effects in the outdoor garden, the stately Delphiniums or perennial Larkspurs are unsurpassed. Ranging as they do in height from 3 feet to more than twice that stature, according to the soil and variety, they can easily be accommodated in beds or borders, or any other positions that it may be necessary to fill. Good blue flowers are not too common—indeed, one might almost say that they are rather scarce—hence we should make

A BEAUTIFUL GROUP OF DELPHINIUMS IN A BORDER OF MIXED PLANTS.

full use of these stately perennials, which embrace so many shades of blue. Fortunately, their cultivation does not call for any special skill. Good, generous diet and attention to a few details that I will mention are all that is necessary. Like every other plant that we undertake to grow, the Delphiniums well repay good cultivation, and for that reason the soil should be well and deeply dug, or, better still, trenched to a depth of 2 feet, and a liberal quantity of partially decayed manure thoroughly incorporated with it. Planting is best done in autumn, *i.e.*, from the third week in September until the end of November, or during February and March, or the first week in April.

For preference one would select autumn, as the plants then have an opportunity of becoming well established before flowering-time, which is usually June and July. As they are plants of goodly dimensions, overcrowding must not be tolerated, and from 2 feet to 3 feet apart is not too much space to allow.

The greatest enemy to Delphiniums, especially those that have been recently planted, is the ubiquitous slug. This insidious pest will, during the winter, scoop out the dormant shoots, and so ruin all prospects of flowers the following summer. It is important to remember this, because to it more failures can be attributed than to any other source. The remedy—a very simple one—is to

cover each plant with a 2-inch thick layer of coal ashes early in the autumn, and see that it is well worked down between the stumps of the old flower-stems.

Summer treatment consists in supplying copious quantities of water during dry weather, supplementing it once or twice a week with weak liquid manure, particularly a few weeks before the flowers open. This makes a wonderful difference in the size, and often the colour, of the blossoms. A 2-inch thick mulching of short stable or farmyard manure over the roots of the plants will also go a long way towards success, and is essential where the soil is at all sandy. It is not generally known that most Delphiniums will give a second display of flowers if properly treated. The *modus operandi* is to cut the flower-spikes down close to the ground as soon as the blossoms have faded, then thoroughly water the plants, and as soon as new growth is active, feed well with weak liquid manure and renew the mulching. If watering is persisted in during dry weather, secondary flower-spikes will soon be formed, and, although not so large and stately as those that opened earlier, will, nevertheless, be very welcome in the autumn months.

The simple operation of staking is, of course, necessary, and is only referred to here because it is so often badly done, the flower-stems being trussed to a stake so that they form a passable caricature of a Birch broom. Miss Jekyll has

adopted the most sensible plan that I know, and one that preserves the natural contour of the plants. Her method is to use natural sticks, such as are usually employed for supporting Peas, three or more of these being thrust into each plant so that the shoots can push their way up between the branches. Very little tying is necessary and the effect excellent.

Delphiniums from Seeds.—Although there are a great many named varieties listed in catalogues, a packet of seed, purchased from a first-class firm, will give a quantity of plants that are not very inferior, and which, for ordinary purposes, answer quite well. The seedlings are not difficult to raise.

The best plan is to sow the seed in shallow, well-drained boxes or pans of sandy soil during April, May or early June, and place them in a cool greenhouse or frame. When 1 inch or 2 inches high, the seedlings must be transplanted to a bed of finely pulverised and well-enriched soil, where, by the autumn, they will have made sturdy young plants that will give some good flowers the following May or June, though not so large as may be expected another year hence.

As Pot Plants.—At the last Chelsea Show some excellent Delphiniums were shown growing and flowering in large pots. For a large and not too much heated conservatory they would be ideal, and ought not to be difficult to manage. It would be necessary to pot up some strong crowns early in autumn, plunge the pots to their rims in ashes in the open or in a cold frame for the winter, and bring them into very slight artificial heat as growth commences naturally. Any attempts at hard forcing would, no doubt, end in failure. The following are some good named varieties that are not too expensive for general planting:

Belladonna.—An old variety with sky blue flowers, which are produced very abundantly. Height, 3 feet.

Christine Kelway.—A tall variety with sky blue flowers and white eye. Considered by many to be an improvement on Belladonna.

Langport Blue.—This is a white variety, 5 feet or more in height. Flowers rich bright blue and spikes bold and large.

Persimmon.—One of the prettiest of all. The flowers are clear sky blue, and are produced in abundance. The plant resembles Belladonna, but has a more robust constitution. Height, 3 feet.

Rev. W. Wilks.—Deep purple, flushed plum colour, with prominent dark eye to each flower. A superb variety. Height, 4½ feet.

Sir George Newnes.—A semi-double variety with beautiful cobalt blue flowers, the inner petals flushed plum colour. Very effective when massed. Height, 4½ feet.

Sir Walter Scott.—Deep rich blue, flushed violet, with prominent black eye or centre. Height, 4½ feet.

Althos.—Rich violet, flushed purple, with white centre. A most charming variety. Height, 5 feet to 6 feet.

King of Delphiniums.—Semi-double flowers of rich gentian blue, flushed plum colour. Each has a white eye that renders the whole very attractive. A strong-growing variety. Height, 4½ feet.

True Blue.—Perhaps the richest coloured of all the Delphiniums, the flowers being pure intense blue. It has a good constitution and grows from 5 feet to 6 feet high.

General Baden-Powell.—Soft lavender, tinted rose, with a brownish black eye. A very restful colour in the garden. Height, 4½ feet.

James Kelway.—Very rich violet blue flowers, each with a pronounced white centre. Very effective when massed. Height, 5 feet to 6 feet.

Princess Maud.—Unique in colour, which is sky blue, veined rose pink, each flower having a white eye. It is semi-double, and of fairly robust constitution. Height, 5½ feet.

Sir Trevor Lawrence.—Sky blue, with the inner petals flushed rose pink, white eye. Good constitution. Height, 6 feet.

Two varieties of more recent introduction, and consequently more expensive, are the Rev. E. Lascelles and Statuaire Rude. The first named has rich violet blue flowers, with

a pronounced white eye. It is tall and very erect. The second is a very stately plant, the large spikes standing well above the foliage. The flowers are a charming shade of soft lavender blue, with a slight flush of rose. They are semi-double and very large. H.

ANNUAL FLOWERS SUITABLE FOR CUTTING.

HOW to obtain a good supply of flowers suitable for cutting and at the same time study economy is a question of some importance in many gardens. As far as can be seen at the present time, there will be an even greater demand than usual this season, for added to the general home requirements will be those eagerly welcomed in hospitals and similar institutions. By making a free and judicious use of annuals, the difficulty is at once surmounted. The following list furnishes

into 3-inch pots and be planted out in May in a sunny position. There is hardly a finer decorative plant among annuals. The *Eschscholtzia*, too, is splendid, and is, I venture to remark, one of the coming annuals.

The need for careful preparation of the soil for such plants has so often been given in *THE GARDEN* that it is superfluous to add thereto. Staking of the annuals should be carried out sufficiently to prevent damage by wind and rain, but not one unnecessary band or stick should be used, as it is most inconvenient to have to wade through a mass of ties when gathering a supply of flowers.

Serlby Gardens, Bawtry.

H. TURNER.

THE HARDY PRICKLY PEARS.

THOSE who appreciate unusual features in the outdoor garden should grow those members of the Prickly Pear or Indian Fig family (*Opuntia*) which are practically hardy in this country. Being of a very succulent nature, they delight in a sunny position, and if a very hot site, where nothing else can be induced to

A BED OF VICTORIA ASTERS. THESE ARE GOOD ANNUALS FOR CUTTING.

ample material for selection: *Antirrhinums (medium and tall; best grown as annuals), Asters (annual, of sorts), *annual Carnations, Clarkias, Coreopsis, Cornflowers, *Cosmos, *Eschscholtzias, *Gaillardias (annual), Godetias, *Larkspurs, Lavatera, Lupines (annual), Mignonette, Nigella, Salpiglossis, Shirley Poppies, *Stocks, Sunflowers, Sweet Sultan and the indispensable Sweet Pea. Those marked with an asterisk should be sown under glass, while the remainder, if desired, may be sown where they are to grow and flower, or in a seed-bed in the reserve garden, to be afterwards pricked out in their permanent quarters. Exceptions to this mode of treatment are the Lavatera, Mignonette and Poppies, which are generally impatient of shifting, so should be sown in their flowering places. The great usefulness of the Antirrhinums, Asters, Clarkias, Godetias and Larkspurs for cutting is fully recognised, but it is doubtful whether Cosmos and the *Eschscholtzia* receive the attention they deserve. An early flowering strain of the former should be chosen, and the seedlings potted singly

grow, is available, the *Opuntias* will be likely to do well there. At Kew they are grown in a recess of the Palm House which faces south, and is, of course, sheltered from the north and east winds. In addition to this there is always a little warmth from the wall of the house, and under these conditions the plants seem quite happy. In all except the warmest localities, however, it will be advisable to so construct the bed that a glass light can be placed over it during the worst weather in winter, a lot of rain, followed quickly by hard frosts, greatly injuring the plants. Generally speaking, a low, roughly constructed rockery is best, as by this means thorough drainage, which is most essential, is secured. A suitable soil is composed of good turfy loam two parts, crushed bricks and sand one part each, the whole to be used in a moderately rough condition. Planting is best done in spring, as the plants then have an opportunity of becoming established by the following winter; but the preparation of the bed may be attended to now. The following are a few that should do well under

the conditions described: *Opuntia camanchica* albispinia, *O. Engelmannii*, the Indian Fig, *O. Ficus-indica*, *O. missouriensis* and varieties, *O. Rafinesquii* and its variety *O. R. arkansana*, and *O. pachyclada rosea*. H.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Crocus biflorus Alexanderi.—A charming variety in which the outer segments of the flower are wholly of a shining chocolate colour, save for a narrow margin of white. The remaining segments are bicoloured, the larger upper half being pure white. Internally the petals are white. It is very free and profuse flowering.

Crocus Imperati albiflos.—

Next to *marathonisus* we consider this the finest white-flowered variety found among autumn or winter flowering Crocuses. The fully expanded flower is pure white, with orange-coloured stigmata. Externally the outer segments are yellowy buff and faintly lined, the lines appearing to penetrate to the inner surface of the flower. One of the largest, most exquisite and free flowering of its race.

Crocus biflorus Lemon Queen.

The great charm of this variety lies in the distinctive cream-yellow of its flowers, a shade of colour of exceptional rarity, wedded to roundly obovate petals. Externally, at the base the flowers are marked by a faint suspicion of purple colour. The whole of these were exhibited by Messrs. Barr and Sons, King Street, Covent Garden, W.C., the well-flowered examples constituting a great attraction.

Primula malacoides Rose Queen.—

Quite the most charming and distinct variation of this Chinese species, which has gained popularity as much by reason of its simple cultural requirements as by its freedom of flowering and elegant habit. The new-comer is of a rosy carmine shade, very pronounced and beautiful. In the examples shown, a greater vigour than that of the type was apparent. From Mrs. Denison, Little Gaddesden, Berkhamsted (gardener, Mr. A. G. Gentle).

Odontioda Patricia (*O. Phoebe* × *O. Charlesworthii*).—The flower is wholly coloured a dark, glossy maroon, the lip pronouncedly tipped pale yellow, with yellow feathering at the centre. A handsome and distinct form. From Messrs. Charlesworth and Co., Hayward's Heath.

Cymbidium Schlegelii Fowler's Variety (*C. wiganianum* × *C. insignis*).—The sepals and petals are of a pleasing rose pink, lined with white; lip white, irregularly and copiously marked with crimson spots and stripes. From J. Gurney Fowler, Esq., Pembury, Kent (gardener, Mr. J. Davies).

Odontoglossum sandhurstiana.—Exhibited by C. J. Phillips, Esq., The Glebe, Sevenoaks. We were unable to locate this novelty.

The foregoing were exhibited before the Royal Horticultural Society on February 16, when the awards were made.

SEASONABLE NOTES ON VEGETABLES.

Rhubarb should be replanted where the roots are becoming exhausted, especially where they have been partly forced by the aid of manure.

around the roots with long strawy manure. The Sutton is an excellent variety for the main crop. Dawe's Champion, Champagne and Mitchell's Royal Albert are good varieties to add.

Spinach should be sown in a cold frame for an early supply, as it is too early yet for an outdoor sowing to be made. The cold rains to follow, combined with frost, are all against the progress of the tiny seedlings; but in a cold frame the plants are immune from these drawbacks and grow away freely, giving an early supply of succulent leaves.

Turnips may be sown in a frame on a slight hot-bed about the third week in the month. White Milan, Red Milan and Early Gem are desirable sorts.

Tomatoes.—Pot on the autumn-sown plants, giving them a liberal shift, and keep close to the glass to induce sturdy growth. Do not give too much water; just enough to keep the roots in a progressive condition. Make another sowing now of maincrop varieties for growing under glass. Princess of Wales, Satisfaction, Perfection and Sunrise are good in the red-skinned section. Golden Perfection and Golden Nugget are good yellow varieties.

Parsnips must be sown directly the soil is in a fit condition. Should it remain wet for some time, for the early crop and best roots boards should be used to stand upon, so that sowing the seed will not be too long delayed, as Parsnips require a long season of growth. Bore holes 3 feet deep, 15 inches apart in rows of the same distance, with an iron bar, filling the holes with fine soil. Nothing is better than old potting soil, as the seedlings grow away quickly from the start, and, being free from stones or large clods, the Parsnips grow with one tap root to the bottom of the hole, the roots coming out quite clean and straight. In the ordinary way, in stony or stiff soil, even if trenching is done, the roots all too often grow forked and short. By the boring method the roots are certain to be long and straight, and, even if not required for show, they are all the better for home use, as so much heavier a crop is assured.

Lettuce may be sown in frames over a slightly heated base to provide plants for putting out early or for leaving in the frames to grow quickly, to be used in a small state for salads. Boxes of sandy soil in a cool house will provide a batch of later plants of a sturdy character if, after the seedlings appear, the plants receive a light position in a cool temperature. Both Cos and Cabbage varieties should be sown.

Shallots must now be planted in a sunny site. A south border suits them admirably if such can be spared. They succeed in the open providing the ground was deeply dug in the autumn and

PRIMULA MALACOIDES ROSE QUEEN, A BEAUTIFUL NEW VARIETY WITH RICH ROSY CARMINE FLOWERS.

Where new varieties are to be added, a thorough overhauling of the roots should occasionally be made. The site selected for a new plantation, or the old if this is to be continued, must be deeply trenched and heavily manured. For the large-growing varieties like *Victoria* the rows should be 5 feet wide and the plants 4 feet apart. Smaller-growing varieties like *Early Scarlet* will succeed with less space. Divide the old crowns into pieces about six inches square, selecting the outer parts. When planting, place about the roots some fine compost, such as decayed leaves, vegetable refuse, or old potting soil. Mulch the surface afterwards

now forked over during dry weather, raked down and made fairly firm. The giant-growing sorts require a space of a foot between the rows and 10 inches in the rows. Smaller-growing sorts require a couple of inches less. Press the bulbs into the soil about two-thirds of their depth. Sprinkle wood-ashes or burnt earth over the surface afterwards.

Cabbage.—Seed should be sown in cold frames to provide plants to succeed those put out in the autumn, selecting varieties like Little Gem and The Earliest.

Cauliflowers may be treated in the same way for an early batch of plants. Sturdy growth, by giving ample space, is the chief aim in this early batch, as drawn-up, weakly plants have a poor chance when exposed to cold April and May winds.

Celery for the earliest crop in August should be sown, just a pinch of seed in a box of sandy soil in gentle heat, potting on the plants as they progress.

Vegetable Marrows for an extra early crop, say, in May, should now be sown in a brisk heat separately in small pots, transferring the plants to larger pots as they require more rooting space. Keep the plants as close to the glass as possible to avoid the growth being drawn up weakly. Tie the leader to a stake, allowing it to grow away uninterrupted. Pinch out the points of the side shoots one leaf beyond the blossoms, which should be fertilised to ensure greater success.

Swanmore.

E. MOLYNEUX.

JOHN EVELYN.

SOME HISTORICAL NOTES.

THE author of "Ecclesiasticus" opens his list of national heroes with these pregnant words: "Let us now praise famous men and our fathers that begat us. The Lord hath wrought great glory by them, through His great power from the beginning. Such as did bear rule in their kingdoms, men renowned for their power, giving counsel by their understanding and declaring prophecies: Leaders of the people by their counsels, and by their knowledge of learning meet for the people; wise and eloquent in their instructions." Tried by this test, the name of John Evelyn deserves to be placed on our roll of national heroes. And yet possibly few know more about him than that he was a great gardener who kept a diary, and whose beautiful home at Sayes Court, near Deptford, was occupied by the famous Peter the Great of Russia when he visited England to learn how to build ships, this last fact being imprinted on the popular mind by the tales of how one of his favourite amusements was to be wheeled in a wheelbarrow about the garden and through the hedges of which Evelyn was so proud. How far this is literally true will never be known, but that it was not all smoke is proved by the amount of damage done to the garden in his three months' stay, being assessed at £150. Undignified forms of locomotion seem to be attractive to rulers; for I was told when I was in Morocco City that the then Sultan took great pleasure in being driven about his grounds in a London twopenny 'bus.

As is so frequently the case, the picturesque tales only are remembered, and the reality or that which really matters is cast aside and forgotten. So it has been with John Evelyn. The wheelbarrow episode has become current coin;

his great work for the British Navy is all but unknown. Who, then, was this man, and what did he do, and why should he be remembered? Evelyn was a widely travelled, deeply thoughtful, keenly observant country gentleman who lived in the times of the Stewart kings and Cromwell, right through the reign of William and Mary until the days of Queen Anne, when he passed away in his eighty-first year.

He had the happy knack of being able to put two and two together, and the faculty of being able to impart his knowledge in a pleasing and readable manner. The long and varied list of his writings, which may be found in the "Dictionary of National Biography," is an eloquent testimony to his versatile intellect and his wide interests.

SYLVA, OR A DISCOURSE OF FOREST-TREES, AND THE Propagation of Timber

In His MAJESTIES Dominions.

By J. E. Esq.

As it was Deliver'd in the ROYAL SOCIETY the xvth of October, C1610CLXII. upon Occasion of certain Quarries Propounded to that Honourable Assembly, by the Honourable the Principal Officers, and Commissioners of the Navy.

To which is annexed
POMONA; OR, An Appendix concerning Fruit-Trees in relation to CIDER The Manner and several ways of Ordering it.

Published by express Order of the ROYAL SOCIETY.

THE TITLE PAGE OF THE FIRST EDITION OF EVELYN'S FAMOUS WORK "SYLVA."

Gardening and forestry were the passions of his life. Again and again in his Diary and other works he refers to these subjects, and thus incidentally we get not only an index of his own individual tastes, but also many incidents and allusions of great historical value, as, for example, when he describes the Brompton nursery of London and Wise as "the greatest work of the kind ever seen, or heard of, either in Books or Travels"; or refers to Sir T. Brown's garden at Norwich as a "paradise of rarities," and to Sir William Temple's at East Sheen as a model of good cultivation, or how he fixes the date for the introduction of Pine-apples by his record of his having tasted the first, which was presented to King Charles in 1661.

Switzer, a celebrated gardener and writer of those days, speaks of Evelyn as being another Virgil, who "was appointed for the retrieving the spirit of his countrymen for their planting and sowing of Woods,—to him it is owing that Gardening can speak proper English." It was this that has made him so justly celebrated, and which in our present distressing times give him an interest which in more peaceful days we might pass over. No one has ever done more for the British Navy than this man did by his giving "counsel with understanding," and by the "wise and eloquent instructions" which he gave to the world in his *magnum opus*, "Sylva, or a Discourse of Forest Trees, and the Propagation of Timber in His Majesties Dominions," which first saw the light of day in 1664. The history of the book is as follows: Somewhere about the year 1662—soon, that is, after the restoration of the monarchy—the authorities responsible for the well-being of the Navy became aware that the forests and woods had become seriously depleted, partly owing to the increase of shipbuilding, and partly and more especially owing to the spread of various manufactures. What was to be done? In their difficulty the Commissioners of the Navy applied for advice to the newly formed Royal Society. They, naturally, turned to Evelyn, who was well known for his knowledge of all things pertaining to horticulture and planting. The result was that he addressed his fellow-members on October 15, 1662, advocating extensive planting of timber trees throughout the kingdom. This "discourse" he expanded and issued in book form in the early part of 1664, under the title of "Sylva."

The title-page of the first edition of this famous work is here reproduced. It will be noticed that bound up with it are "Pomona," or a discourse about cider, and the "Kalendarium Hortense," or monthly notes on what should be done in gardens. This last item is memorable as being of the earliest forerunners of the now never-omitted "Work for the Week" columns of the gardening weeklies. The result of the address and the publication of this was instantaneous. In the 1678 edition he is able to state in his dedication to the King that "many millions of timber trees, beside infinite others, have been propagated and planted throughout his vast dominions at the instigation and by the sole direction of this work."

A hundred years later (1776) Hunter, in his preface to his famous illustrated edition of the "Sylva," states that "there is reason to believe that many of our ships, which in the last war gave laws to the whole world, were constructed from Oaks planted at this time." He adds: "the present age must reflect upon this with gratitude." Needless to say, we do the same to-day, for if the oaken walls of old England have passed away and given place to iron, the maintenance of our Navy has always been of paramount importance to the British Empire. A few words in conclusion to enable readers to form an idea of its contents. Both useful and ornamental trees are included. Their uses are defined. Interesting bits of historical information are recorded. The management of the seminary, the management of copses, the infirmities of trees, and the laws and statutes for the preservation in improvement of woods are enumerated. Seasoning of timber, pruning, and many other topics are dealt with, the whole forming even now a most interesting and readable volume, and one which, I venture to think, every Britisher should know about.

JOSEPH JACOB.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Planting One Year Old Vines.—It is too early yet to plant Vines, but the new border will be all the better if made several weeks before the Vines are ready to plant, which is just when they are breaking naturally into growth. The whole of the old soil should be removed, and, while the house is empty, the opportunity should be taken to paint the woodwork and trellis. In making the new border, see that ample drainage is provided, and to ensure the porosity of the soil mix plenty of broken bricks and charcoal with it. Use artificial manures with caution. Crushed bones or a special Vine border compound will provide ample food for the young Vines if the soil is good. A border about four feet wide will be sufficient for the first two years. For early Vines a depth of 2 feet 6 inches is ample, but late Vines should be allowed a little more.

Late Vines.—The starting of late Vines must be governed more or less by local conditions. From the beginning to the middle of March will usually be found late enough for such varieties as Lady Downe's Seedling, Gros Colmar and Lady Hutt. Alicante and Appley Towers do not require quite so long to ripen their fruit, and this fact should be borne in mind when planting a house of late Grapes. If mealy bug is present, both Vines and vinery must be thoroughly cleansed. The loose bark must be removed from the rods. Afterwards thoroughly scrub them with hot soapy water two or three times.

Outside Fruit Borders.—To encourage roots near to the surface, outside borders require their annual top-dressing just as much as inside ones. The old soil should be first removed down to the roots, replacing it with fresh chopped loam, brick rubble, crushed bones and wood-ashes.

Plants Under Glass.

Chrysanthemums.—Pot on young plants before they become pot-bound. They like a fairly rich compost, which may consist chiefly of loam, leaf-soil, wood-ashes and sand. Pot firmly and keep them growing near to the glass in a cool house. Fumigate occasionally to keep them free from aphids.

Clivias.—These will now be pushing up their blossoms, and should they be required to flower early, they may be placed in a warmer house. Give them plenty of stimulants now in order to put colour and strength into the flowers. Any repotting necessary may be done after flowering.

Begonia Gloire de Sceaux.—When well grown, this makes a handsome specimen. The plants will be passing out of flower, and attention must now be directed to the propagation of a new batch of plants. Slightly cut the old ones back and place them in a warm house, where they will make young growths suitable for cuttings.

Coleus Hybrids.—Seeds may be sown now for raising a batch of plants for a summer and autumn display. A batch of cuttings may also be inserted.

Bouvardias.—These may be propagated by dividing the roots and laying them in pans or boxes filled with sand. Pot up the young plants into 3-inch pots as soon as they are large enough.

Sowing Seeds.—Seeds of Gloxinias, Streptocarpus, Celosia, Francoa, Clerodendron fallax, Primulas for autumn flowering, and various annuals for flowering in pots may be sown now.

The Flower Garden.

Pentstemons.—Sow seeds of these now in boxes in a light compost. The resultant plants will flower in the late summer and autumn. Plants raised from cuttings last autumn will be the better for a shift either into pots or to a bed of soil in a cold frame. Pentstemon barbatus is an excellent plant for providing flowers for cutting, and a batch of plants should be grown specially for this purpose. These may be increased now by division of the roots.

The Woodland Garden.—Any work requiring attention in this part of the pleasure grounds should be attended to at once, so that there will be nothing to interfere with the early spring effects. Any surplus herbaceous plants which

are suitable for massing in the wild garden, such as Senecio Clivorum, Chrysanthemum maximum, Helianthus, Doronicum, Lythrum, Erigeron, Epilobium, Pyrethrum, perennial Asters, and Solidagos, should be made use of. Foxgloves, Physalis and Honesty are most suitable subjects for naturalising in the woodland garden.

Herbaceous Lobelias.—The plants which have been wintered in boxes in frames may now be divided and potted up. Place them in a heated pit for a few days to encourage root action, after which they may be returned to a cold frame.

The Hardy Fruit Garden.

Outdoor Vines.—If these are not already pruned, no time must be lost in doing so. If the planting of Vines outdoors is contemplated, a warm, sheltered position must be selected and a well-drained rooting medium prepared for them.

Spraying Fruit Trees.—The advantages of spraying fruit trees are now universally recognised. The work may be done any time now before the trees burst into growth. Dull, windless weather with the temperature above freezing point is most favourable for this operation.

The Kitchen Garden.

Mushrooms.—The manure for making the beds must be collected in a dry shed. Turn the heap every two or three days to allow the rank gases to escape. Mushrooms may be easily grown in a dark shed after this date, but the bed must be covered with a good coating of clean straw.

Potatoes.—The tubers which are lying in a heap in a shed will be better if overhauled. Carefully look for those which are tainted. During mild weather admit as much air as possible to the shed. A small plantation may now be made on a sheltered border.

Radishes.—Small sowings of these must still be made in frames to keep up a supply.

Turnips.—To be on the safe side, it is a good plan to make two or three sowings for an early supply. As soon as the young plants are through the soil, lightly dust them with wood-ashes and soot.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Filling Up Blanks.—Wallflowers and other spring bedding plants will now be starting to grow, and where any deaths have occurred, the blanks should be filled up with plants from the reserve garden.

Herbaceous Borders.—Even with manuring and the annual fork over, these borders require periodical overhauling. It not only gives an opportunity for trenching and adding a quantity of good manure, but most of the plants benefit by being split and replanted; especially is this the case with such herbaceous plants as Michaelmas Daisies. Some plants, however, are more impatient of disturbance, such as Pæonies, Lupines and Papavers. These should, if possible, not be disturbed during the trenching of the border. Old plants of Phloxes are best discarded and replaced with young plants which have been propagated from cuttings. Notes having been made of plants which were not quite suitable for the positions they occupy, substitutes may be put in when replanting.

Early Flowering Chrysanthemums.—A start should be made with the propagation of these. Young stock is always the most satisfactory. Cuttings are very easily rooted, either with or without bottom-heat. A simple mode is to dabble the cuttings closely together in boxes of sandy soil, deep enough to allow the cuttings to be covered with glass, until they are rooted.

Bedding Geraniums.—Where plants have been wintered several in a pot, or in boxes, a start should now be made to pot these up singly. They benefit from a close, warm house for a time after potting; a Peach-house or vinery suits them well. They should, however, be removed before the foliage

of fruit trees becomes dense, or the plants quickly become weak and drawn.

The Kitchen Garden.

Tomatoes.—The early sown batch of plants are now ready for potting into 6-inch pots, and it should be seen that no time is lost in doing this. A small quantity of fertiliser may be added to the compost for this potting.

Early Cabbages.—Any blanks should be made good as soon as the condition of the soil permits. A small application of nitrate of soda around each plant will encourage a quick growth. After removing any large weeds, the ground should be gone over with the Dutch hoe.

Onions which were sown under glass some time ago must now be pricked out singly, allowing 3 inches between the plants. Use for the soil good loam and leaf-soil, with a good sprinkling of wood-ashes and sand. After pricking out, they may be kept in a genial growing temperature for some time until they have got a good start; afterwards they should have cooler treatment.

Celery.—A small sowing can be made now if an early supply is required, taking care to see that the soil in which the seed is sown is kept moist. Boxes are most convenient for this sowing, and should be placed in heat until the seed has germinated.

Plants Under Glass.

Impatiens.—Seed sown now of this subject will produce flowering plants for making the greenhouse gay in July and August. The Holstii hybrids are of a glowing orange scarlet, while the variety Sultani is pink. Sow in a fairly brisk heat, then grow in an intermediate temperature.

Fuchsias.—Plants that have been resting ought now to be pruned, and any requiring repotting should have attention. A warm greenhouse is best in which to start them, and they must be regularly syringed during bright weather until growth is well advanced.

Palms.—To keep them in good condition, all Palms must be overhauled at this season. Large specimens do not require a change of pot for several years, while younger plants need larger pots as the Palms develop. Any not in need of repotting may have the spent surface soil removed and top-dressed with some new compost. In all cases the drainage of each pot should be examined. Clear soot-water is perhaps the best fertiliser for keeping Palms in that healthy dark green colour so much desired by growers.

Achimenes.—Whether used for baskets or growing in pots, the bulk of these should now be started to get a good display in summer. The corms of some varieties being very small, great care is needed when picking them out of the old compost. The soil for growing these plants should contain a large percentage of peat, leaf-soil and silver sand.

The Hardy Fruit Garden.

Strawberries.—After being cleared of any weeds which may be growing, the plantations should be lightly forked over, adding a light dressing of bone-meal or some fertiliser as the work proceeds. Any blanks among young plants should be made good before they commence to grow.

Orchard Trees.—All ground in which fruit trees are growing, if not already done, ought now to be forked over, after having received some well-decayed farmyard manure or, failing this, some artificial fertiliser. The forking of the ground near the trees should be very light, and the use of the spade is to be condemned.

Gooseberries.—The pruning of any bushes which was purposely delayed, in view of possible attacks from bullfinches, ought not to be delayed much longer, now that the buds are showing green. All branches that are lying low on the ground should be removed, as any fruits produced on these are very liable to be splashed with soil during heavy rains. The rest of the pruning will largely depend upon how the remaining branches have been attacked. Those which have few buds remaining are best removed altogether.

JOHN JEFFERY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

HINTS ON PRUNING ROSES.

It is, of course, too early to prune the general collection of Roses, but there are certain groups which can be pruned now that will lessen the labour a little later, when so many calls are made upon one's time.

Take, for instance,

Rose Hedges.—Old wood may be freely removed, and if growth has become rather bare at the base, a shoot or two upon each plant may be cut down nearly to the ground. The final shortening of the annual growths should be deferred for another fortnight. Some good farmyard manure dug in on both sides of the hedge will be well repaid during the summer. It is not wise to allow these Rose hedges to become too dense in the matter of growth, for then they make a capital lurking place for many foes, and thus prevent birds from detecting their presence.

Old-Fashioned Roses.—In many gardens, no doubt, there are still grown the old-fashioned Gallica, Hybrid Chinese and Moss Roses. Such may be pruned now. Here, again, old wood may be cut away freely, but I do not advise a too severe pruning of the last year's wood if a quantity of bloom is desired. Indeed, I have seen this type of Rose left practically unpruned, and the branches have been smothered with bloom. Of course, this would not do each year, otherwise we should have very little new growth of any strength, and the plants would deteriorate. It is a good plan to prune some plants severely and leave some unpruned each year, taking care that those unpruned one year are pruned hard the next.

The Briar Family.—Practically all the Briar family require very little pruning, except to free them of some of their old wood. In these we can copy the wild Roses of the hedgerows, which give such a glorious display from their last summer's growths, whereas the older growths, all studded with short twigs, are never so beautiful. Most of the Rose species are best left alone, except for a slight thinning out of the oldest growths. All this work may be done now, and the plants assisted by forking in manure around them.

Rambler Roses, as is generally known, receive their chief pruning soon after they have bloomed; but it may be that from circumstances beyond our control this work has been neglected. If so, cut away at once a good lot of the oldest wood. This applies more especially to the multiflora section, as this group certainly flowers best from the one year old wood. Supposing there is not a goodly number of one year old growths, then some of the previous year's shoots may be retained, and even older growths that sent out good young shoots last summer may be also retained another year for the sake of the younger branches, which should be shortened a little about the middle of March. The old wood of wichuraiana Roses retains its vigour for several years, and if large spaces are to be covered, there is no reason to remove it; but where these Roses are grown in restricted places, then it is much better to cut away old wood freely and tie up the young growths. Those fine pot-grown specimens seen at the Chelsea Show have rarely more than three or four one year old growths, which yield the glorious big clusters.

Weeping Roses may be thinned now of old wood, although in their case the work is best done in August. As I go about I see huge heads to these weepers, with a dense mass of twiggy

growths. If such had been well thinned and long, drooping growths encouraged, they would have been far more effective.

Roses on Walls may be pruned about the first week in March. The new wood that is well matured should be laid in wherever possible, and some old wood cut away. Healthy old wood bearing sound laterals may be retained and the latter shortened, the weakest to two or three eyes, and those stronger to 1 foot or 2 feet or more in length. Where wall Roses have become bare at the base, this may be remedied by taking down the plant and, carefully bending it in a zigzag fashion, fasten it to the wall in this position. It needs much care to prevent breaking; but if the bends are made carefully, in course of time new shoots will emerge from them. Roses on sunny walls having a glass coping should have what growth it is necessary to remove cut away at once, but this ought to be very slight. Roses of the type of Marie van Houtte yield a glorious quantity of buds if grown under such conditions, and they require very little pruning.

Budded Stocks.—Stocks that were budded last summer should be cut back at once. Standard Briars should have the side growths that contain the buds cut back to about three inches from the bud, and all other side shoots that have no bud must be cut close to the stem. The top of the Briar should also be cut back close to the topmost lateral growth. To prevent damage by the sawfly laying its eggs in the pith, it is a good plan to smear over some painter's knotting or liquid grafting wax. Dwarf stocks, such as seedling Briars, Briar cuttings, Manetti, &c., should have their tops cut off now to within an inch at most of the inserted bud. I prefer to cut as close to the bud as possible. Bamboo canes should be placed close to the stocks at once to mark their position, as it is advisable to lightly dig over the surface as soon as the weather permits. Do not allow the buds to be covered up with soil. The more they are exposed, the harder they will be. Any buds which shot out during last autumn should be cut back to their base. Where pot Roses are grown, there will doubtless be a batch of plants left for later crops. These should be pruned now and placed in a pit ready for removal to the forcing-house when desired. Roses potted up last October may be pruned during the next two weeks, and if pits are available, let the plants be plunged therein. Such plants give blooms fully a month earlier than those outdoors, and the steady growth made in the unheated structure just suits them. The plants are plunged outdoors after flowering, and make splendid material for earlier forcing another season.

Polyantha Roses are now largely employed for summer bedding. Many gardeners find it best to bring on the plants in pots in cold frames, and either plunge them in the beds to follow the bulbs or plant them out as permanent bedders. By having a batch of plants plunged in their pots for the summer, we thus may use the same plants in the forcing-house the next winter, where they make most delightful subjects for conservatory decoration.

DANECROFT.

BOOKS.

Gardener's and Florist's Annual for 1915.—

Although this is an American publication, we think gardeners and nurserymen in this country will find it a very useful handbook for reference. It is one of the best compiled books of its kind

that we have seen, and the business section, devoted to such subjects as banking, insurance, exporting and importing, is invaluable to commercial men and women. The hints and recipes are concise and good, and many of them would be applicable in this country. For instance, fumigating with hydrocyanic gas for the purpose of destroying mealy bug and other insects in greenhouses is a subject about which too little is known among gardeners here, but full particulars for its use are given on page 124 of this book. The agents for the publication in this country are Messrs. Pearson, Lowdham, Notts, from whom copies can be obtained, post free, 2s. each.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PLANTS FOR MIXED BORDER (Headley).—In view of the great wealth and choice of hardy plants to-day, we should eliminate the following numbers from the list: Nos. 3 and 4, desirable enough, but tender and rarely a success; No. 5, quite unsuitable; No. 7, inferior species; No. 10, unsuitable; Nos. 12, 13 and 15, of third-rate merit; No. 16, better in the rock garden; Nos. 18, 20 and 21, suitable only for the rock garden; No. 22, we do not know. Of the remaining seven kinds between, Nos. 1, 8 and 15 would require a 6-feet high stake; No. 9, a space of 2 feet to develop its ornamental leaves; while all would do in the soil you mention. Nos. 1 and 2 are interesting rather than very showy, and neither is long-lived. No. 9 is highly ornamental when established, and No. 11 the best flowering plant in like circumstances. No. 19 should be planted, a dozen or a score of single pieces, at 1 inch or 2 inches asunder to form a group. Nos. 18 and 20 are increased by seeds and by the division of their tiny scaly bulbs when at rest. No. 21 may be propagated by means of "heel" cuttings in June and by seeds when these are available.

GARDEN BED AND CLIMBERS (H. A. Pryer).—As the front garden abuts on the main road and trams and buses are frequent, we think the Cannas would not be much of a success unless you keep them free from dust. The Stocks might gather more dust than these because of their woolly leaves, and probably Godetia or Snapdragons would render equal service if less fragrant. If you know the colours of the Cannas, you might select Snapdragons for either harmony or contrast, and the plants are easily grown and free flowering. A particularly good plant for such a bed, though it might compete with the Cannas at flowering-time in your case, is Salvia Glory of Zurich, vermilion scarlet. Better than all, perhaps,

since you lean to "dot plants of Cannas," would be to plant and peg down on the surface of the bed pink Ivy-leaved Pelargonium Mme. Crousse or Heliotrope President Garfield, the former very charming in colour, the latter ideally fragrant, and both very profuse flowering. For the back garden, if the positions near the Poplars were prepared, all the climbers save the Tropaeolum would, we think, succeed. Much depends upon the length of time the trees have occupied their places. For the Tropaeolum about half the bulk of soil should be replaced by leaf-mould and sand, while for the others a considerable addition of light material would be a great gain. None of the plants named takes kindly to clay at the start.

PLANTING FLAG IRISES (*Namptwyche*).—The best planting season for these is March - April, and you will not go far wrong if you follow the dictum of Mr. E. H. Jenkins as laid down in "The Hardy Flower Book," since few men have so wide a practical experience as he of these and allied subjects. The selection given by you is very good so far as it goes. It would be more complete if you added Chelles (yellow and bronze), Dr. Bernice (smoke and bronze crimson), Victorine (white, purple splashed) and Princess of Wales (white, very early). The typical pallida is also worth adding; it is so compact and free, and distinct from all. The difference of price is often governed by the stocks held, though occasionally also by the quality of the plant; but 20s. per dozen for dalmatica and 15s. per dozen for Queen of May are excessive. At the same time it is best to pay a reasonable price. The firms named would be regarded reliable and, indeed, some of them specialise in this fine race of plants.

TREES AND SHRUBS.

PRICE OF TIMBER (A.).—There is no fixed price per cubic foot for English timber; the price varies considerably, both from time to time and in different places. A few days ago in adjoining counties a difference of 8d. per cubic foot occurred in the price of Oak timber at auction sales, so much depending upon the quality of the timber, quantity of each kind, conditions of extraction and local demand. The price certainly has shown an upward tendency of late, but not to any marked degree. For good timber the following prices per cubic foot may be expected: Larch, 1s. to 1s. 2d.; Scots Pine, 6d. to 8d.; Oak, 1s. 8d. to 2s. 6d.; Ash, 1s. 9d. to 3s.; Sycamore, 1s. to 2s. 6d., according to size and freedom from knots; Elm, 9d. to 1s. 2d.; Sweet Chestnut, 1s. 3d. to 2s.; Beech, 6d. to 1s. 9d.; Poplar, 8d. to 1s.; Alder and Birch, 6d. to 9d. Your best plan will be to grade your timber into suitable lots, keeping the good timber of each particular variety together, and the wood of inferior quality in separate lots. When good and bad timber are mixed, the price is often decided by the poor instead of the good timber. When you have lotted all your timber, either sell it by auction or invite tenders from several different people. You must make it quite clear that your liability ends in the sale of the trees, and you ought to stipulate that the timber shall be removed and any damage to fields, gates, fences or roads made good within a specified time. If the timber is fit for pit props, you may be able to dispose of it to a colliery if there is one in the vicinity.

HINTS ON PRUNING SHRUBS (*H. Lefroy*).—By the purple-flowered Buddleia we infer that you mean one of the varieties of *B. variabilis*. That being the case, you may cut last year's shoots back to within two or three buds of the base at once. The orange-flowered Buddleia (*B. globosa*) does not require regular pruning, but if bushes are becoming overgrown they may be pruned back fairly severely as soon as the flowers fade. The winter-flowering Honeysuckle does not require regular pruning, but if the bushes become very dense some of the inner shoots can be cut away as soon as the flowers fade. These three plants may all be given a surface-dressing of well-decayed farmyard manure in May, or you may, if you so wish, give two or three applications of liquid cow-manure during the growing season. *B. variabilis* varieties are benefited by a good surface-dressing of cow-manure each year. *Magnolia stellata* may be left unpruned. Providing it is healthy and fairly vigorous it does not require feeding heavily, but may be given a surface-dressing of decayed manure and leaves. Should a plant appear to be sickly, lift it in April and replant in sweet, well-drained soil containing a little leaf-mould and peat. The different kinds of Heaths require no other pruning save the removal of the flower-heads as soon as the flowers fade. The best food material is a top-dressing of well-decayed leaves. It is a mistake to begin feeding with strong manures, for if the soil is only moderately good it will grow good Heaths, providing it does not contain lime. Heaths may be increased by seeds, cuttings or layers, cuttings being a very popular way. They are made of quite tiny side shoots, 1 inch to 1½ inches long, in July or August, and are dibbled into pots of firm sandy peat and stood in a close, slightly warm or cold, shaded frame until rooted. They are then planted out in a border or cold frame about two inches apart each way, and the points of the shoots are removed occasionally to induce a bushy habit. At the end of the first year they are transplanted and given more room, and when two years old they can be planted in permanent positions. Layering is practised during the spring and early summer, the branches being weighted down into light soil by means of stones, and left two years before removal. The young plants are then placed in nursery quarters for a year prior to permanent planting. Seeds are sown in pots or boxes of fine peaty soil as soon as ripe, or in the following spring. They are kept beneath glass until seedlings appear. These, when large enough

to handle, are pricked out in boxes and treated eventually in the same way as rooted cuttings.

ROSE GARDEN.

MILDEW ON ROSES (*P. T.*).—We think you will find potassium sulphide (liver of sulphur), dissolved at the rate of 1oz. of the liver of sulphur to three gallons of water, and sprayed on at intervals of about a fortnight in the evening or early morning, a check to the spread of the mildew, though nothing will stamp it out altogether, we fear. Pruning away affected parts in March and April will be a useful method also to adopt. Take care that the liver of sulphur is fresh and has not been exposed to the air. Seride is a good proprietary article for destroying mildew. See reply to *S. Clements*.

MILDEW ON POT ROSES (*S. Clements*).—Undoubtedly one of the best remedies both for indoor Roses and those outside is Seride. You can obtain this from Messrs. M. Gleeson and Co., 41, High Street, Watford. Give the Roses a good spraying with this preparation, and we think you will find it will destroy the fungus, only, of course, you must continue to spray at intervals, as mildew is constantly showing itself upon the young, tender foliage of Roses.

THE GREENHOUSE.

CULTIVATION OF VARIOUS PLANTS (*F. B. L.*).—*Veltheimia viridifolia*.—This bulbous plant should, after flowering, be watered as before, until the leaves begin to turn yellow, which is not likely to be for some time yet, for the plant has to make its growth ready for another season. Annual repotting is by no means necessary; but if in your opinion the plant needs a shift, this should be done directly the flowers are over. A compost made up of two parts of loam to one part of peat or leaf-mould and a liberal sprinkling of sand will suit this *Veltheimia* well. On no account should the plant be knocked out of the pot to ripen; in fact, it must be allowed to ripen off gradually and naturally. Should you decide not to repot it, an occasional weak dose of guano or Clay's Fertilizer will be beneficial. As the plant goes to rest, it should be given just enough water to keep the soil from becoming parched up until signs of growth are again manifest. *Streptosolen Jamesonii*.—Presumably this is in a pot in the greenhouse. If too straggling, last year's wood may be cut back sufficient to form a shapely specimen. This will lead to young shoots being pushed out, and as soon as these are about half an inch in length, the plant should be repotted. In carrying out this, as much of the old soil as possible should be removed without unduly distressing the plant. A suitable compost is three parts of loam to two of peat or leaf-mould and a little sand, the whole being thoroughly incorporated together. The flowers are produced on the young shoots of the present year. When the pots are well furnished with roots, but not before, an occasional stimulant will be helpful. Either guano or Clay's Fertilizer may be given, or the two may be used alternately. *Thunbergia laurifolia*.—Any old and exhausted wood may be cut out, but the main shoots should be retained if there is space enough for them. If not, they may be shortened back to half their length. It is quite possible that your plant would be benefited by repotting; if so, now is the best time to do it. A mixture of loam, leaf-mould and sand will suit it well. If in your opinion the plant does not need repotting, you may give it a fertiliser occasionally; but if it is repotted, no stimulant should be given till the pot is well furnished with roots.

ADVICE ON DIFFERENT PLANTS (*T. H.*).—The name of the variegated-leaved shrub is *Eunymus radicans* variegata, and the grass apparently a *Carex*, but it is impossible to say without flowers. The cultural directions for the two plants concerning which you enquire are not at all difficult. *Coleus thyrsoideus* is very readily struck from cuttings in the spring when the young shoots are about three inches in length. The stouter shoots make the best cuttings, as they form more shapely plants than the weak ones. The cuttings should have the bottom pair of leaves removed, and then be inserted singly into small pots in a mixture of loam, peat or leaf-mould and sand, the whole being passed through a sieve with a quarter of an inch mesh. Then, placed in a close propagating-case in a structure warmer than that of an ordinary greenhouse, they will root very quickly. Directly this happens the young plants must have more air, and the point of the shoot must be pinched out in order to encourage a bushy habit of growth. It will also probably be necessary to repeat this later on. The plants must be shifted on, when necessary, in a mixture of loam, leaf-mould and sand, about two-thirds of loam to one of leaf-mould being a very suitable mixture. Good flowering examples may be grown in pots 6 inches in diameter. As the pots get full of roots, an occasional stimulant will be very beneficial. Cuttings taken in the summer and not pinched will flower well in comparatively small pots. In the autumn and winter the flowers develop best in a temperature of 50° to 65°. *Linum trigynum* should, when the flowers are over, be placed in a structure warmer than an ordinary greenhouse, say, where a minimum night temperature of 55° is maintained. They will then soon start into growth, and the young shoots strike readily under the same conditions as advised for the *Coleus*. The growing point, too, must be pinched out in order to induce a bushy habit. During the summer this *Linum* succeeds best in a cold frame, which should be shut up in time to husband a little sun-heat. Like the *Coleus*, an occasional stimulant will be useful as the pots get furnished with roots. For the autumn and winter the same temperature will suit both plants. The old plants of *Linum*

may, if required, be kept over for another year by shortening any straggling shoots, and, as soon as new ones are produced, the plants should be shifted into pots a size larger than they were in before. The same treatment as advised for young plants should be followed.

FRUIT GARDEN.

FUNGUS ON PLUM TREE (*J. S.*).—The fungus is certainly *Stereum purpureum*, the one to which silver-leaf in Plums is attributed. It never fruits on living wood, but only on parts that have died. If the stump has been cut for two years, it is quite possible that the fungus has invaded it since cutting; but if it were left in the ground, it may not have died until the present season. In any case its presence is a menace to neighbouring trees.

KITCHEN GARDEN.

MANURING KITCHEN GARDEN (*A. J. C.*).—If yours is a clayey soil, you can do without potash salts, as the lime you have used will have set free a sufficient quantity for most crops. If not, it would be well to add wood-ashes as well as the superphosphate and sulphate of ammonia, as these will supply the potash required and usually present in but small quantities in light soils. Use 2oz. to 4oz. to the square rod, not more, and do not allow the ingredients to be washed by rain before applying them to the soil.

MISCELLANEOUS.

GRUB FOR IDENTIFICATION (*Mercury*).—The grub is that of the garden swift moth. Fork in Vaporite or any other naphthaline compound about the roots, and in June see that the moths are captured with a butterfly net; they may easily be seen at dusk as they flit ghost-like over the beds. The larvae feed on all sorts of fleshy roots.

NAMES OF FRUIT.—*C. Willmott*.—The Apple is practically identical with Tower of Glamis.—*J. C. C.*—Bowhill Pippin.

SOCIETIES.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening, the 15th inst., there was a meeting of the executive committee of this society, when Mr. Thomas Bevan presided. In presenting the report of the finance committee, which appeared to give general satisfaction, the secretary stated that, all circumstances considered, it was recommended that the publication of the National Chrysanthemum Society's Transactions should be deferred, and this was agreed to without opposition. It was also stated that for the 1915 show the schedule of classes will take the form of a supplement to last year's schedule, certain matter in that being applicable to the present year, and this was also approved of.

The deputation appointed to wait on the Royal Horticultural Society and to make arrangements for the National Chrysanthemum Society's autumn show at the Royal Horticultural Hall, Westminster, expressed their gratification at the cordial manner in which they had been received by the Royal Horticultural Society's officials and the satisfactory result that had been come to. The show will be held there on November 11 and 12 next. It will be open to members of the National Chrysanthemum Society and, of course, to the Fellows of the Royal Horticultural Society, but non-members of these societies will have to pay 1s. for admission. The action of the deputation was confirmed by the committee.

The budget for 1915 was then submitted and passed. The schedule sub-committee were authorised to complete and issue the supplement referred to above, and then followed the election of the various members for the different committees. As one-third of the floral committee retires every year, the necessary vacancies were filled by the appointment of Messrs. P. A. Craig, W. Newton, J. R. Riding, W. Wells, R. Leach and Runciman, who will serve till 1918. With few alterations the following were reconstituted as before: the finance, schedule and publication committees. With regard to the 1915 Conference, it was resolved that all details in connection with it be left in the hands of the schedule committee to complete, and the same course is to be pursued with regard to the proposed series of educational meetings.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

THERE was a very good gathering of members on Wednesday evening, February 10, to hear a lecture on "The Cultivation of the Apple," by Mr. F. G. Drew of University College, Reading. By means of large diagrams, the mechanical analyses of several soils were shown and their good and bad points demonstrated. Temperature, rainfall and soil were points which required consideration when planting trees. Other topics discussed were how to plant trees, pruning, storing the fruit, the fruit-room, diseases and pests and the best means of combating them. A list of the best varieties of fruit concluded a most interesting lecture. A good debate followed, and Mr. Drew answered numerous questions. He also exhibited boxes of Apples, showing his method of packing fruit for market. A hearty vote of thanks was accorded him at the close. Messrs. Waterer, Sons and Crisp, Limited, staged a nice exhibit of hardy flowering plants. Three new members were elected.

THE GARDEN.

No. 2259.—VOL. LXXIX.

MARCH 6, 1915.

NOTES OF THE WEEK.

An Interesting Crocus.—Although it is a great many years ago since *Crocus susianus* was first introduced into our gardens, it is still one of the most charming of the early spring-flowering set, owing to its curiously reflexed flowers. It is suitable for almost any position, and we have seen it used with good effect naturalised in the grass, although it does not increase so rapidly as some species. It is one of the few Crocuses, if not the only one, that reflex in this peculiar way, and when the flowers are half open the brownish purple feathering on the outside harmonises with the deep orange of the inside of the segments.

The Double Red Peach.—Among the numerous hardy trees and shrubs used for the decoration of the conservatory or greenhouse at this season, the Double Red Peach, *Prunus persica magnifica*, is one of the most effective. Naturally flowering outside at the end of March and early in April, the plants do not require a very high temperature to force them into bloom during February. The flowers are rich carmine red, a rather lighter shade under glass than in the open air. These are borne along practically the whole length of last season's growths. As many of the shrubs are semi-pendulous, this adds considerably to their pleasing effect.

A Beautiful Winter Heath.—The *Erica* illustrated on this page is the most useful winter-flowering variety of the whole genus, the plants frequently commencing to blossom during November and continuing the display until April is well advanced. In the past it has been named *E. mediterranea hybrida*, but Mr. W. J. Bean, in his new work on trees and shrubs, adapts the specific name of *darleyensis*. It is, as will be seen in the illustration, a very free-flowering plant, the rose pink blossoms defying the most rigorous weather. It should be planted in bold masses, in soil that is fairly light, well drained, and contains plenty of decayed leaves or some coarse peat. It is a stronger grower than the better-known *E. carnea*, the plants quickly attaining a height of a foot, and subsequently, if left alone, nearly twice that height. It is usually regarded as a hybrid between *E. mediterranea* and *E. carnea*.

Cytisus fragrans.—In most parts of the country this Canary Island shrub is properly regarded as a greenhouse plant, but in Devonshire, Cornwall, South Wales, Ireland and some other places it is grown out of doors as an ordinary shrub, and under the more natural conditions it develops amazingly, forming a bush 4 feet to 6 feet high, with a graceful habit and long branches, which in early spring are clothed with bright golden,

An Evergreen Chinese Barberry.—Among a number of new species of comparatively recent introduction from China, *Berberis candidula* is one of the most distinct. It forms a dwarf, bushy plant 1½ feet to 2 feet high. With age this height will probably be exceeded, but growth is slow. In some respects this latter trait is an advantage, particularly when one is able to plant *B. candidula* in the rock garden. Other positions to plant it are in formal beds in the pleasure grounds and the front of the shrubbery border. The leaves are dark shining green above, contrasting effectively with a silvery under surface. The flowers are yellow, followed in the autumn by purplish black fruits.

Effect of Radium on Plant Life.—We have just received from Messrs. Sutton and Sons a bulletin giving details of experiments conducted in their trial grounds at Reading with radio-active ores and residues. Full details of these experiments were published in our issue for August 15, 1914, page 419. The bulletin now before us gives the whole of the results achieved, most of which, however, were not quite conclusive. We understand that some, at least, of the experiments will be continued during the present year, when it is hoped more definite results will be obtained. In the meantime, anyone who is interested in the subject will be well advised to obtain the bulletin, which can be had from Messrs. Sutton and Sons, Reading, price 2s. 6d. net.

A New Rose Species.—*Rosa sertata*, a new species, is likely to prove an interesting addition to our shrubberies, as well as being suitable for Rose gardens where free-growing and single-flowered kinds are encouraged. A native of China, seeds were sent to Messrs. J. Veitch by Mr. E. H. Wilson in 1907, and by that firm plants were distributed a few years later. Although of weaker growth, it has much of the general appearance of the Himalayan *R. webbiana*. It appears as if it will grow 4 feet or 5 feet high, with a rather loose but graceful habit, the branches being clothed with leaves 3 inches to 4 inches long, made up of from seven to eleven oblong leaflets. The flowers are often borne singly, and are rather more than 2 inches across, deep rose in colour, and succeeded by bright red fruits. Like other Roses, it gives excellent results when planted in good loamy soil.

A COLONY OF THE HARDY HEATH (*ERICA MEDITERRANEA HYBRIDA*). THE PHOTOGRAPH WAS TAKEN A FORTNIGHT AGO.

fragrant blossoms that almost hide the leaves. The more vigorous and finer-flowered variety *elegans* is grown in the same way, and gives a much better account of itself than when grown in pots, although as a pot plant it is one of the showiest spring-flowering shrubby greenhouse subjects we possess. It is possible that both of these plants would succeed against warm walls in many gardens; at any rate, they are worth a trial.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Home-grown Vegetables and Our Food Supply.

I have much pleasure in stating that a good many of our members have already made arrangements for growing extra vegetables in their gardens this year, and we are placing your article on the agenda of our next meeting, when suggestions for a special exhibit of vegetables to be shown at our annual show will be discussed. We have much pleasure in endorsing your suggestions.—JOHN T. GODDARD (Hon. Secretary), *The Crown-field Horticultural Society*.

—The article in your issue of the 6th ult. was discussed by the council of this society at a meeting on February 23, and was adjourned for further consideration at a special meeting to be held for that purpose. I may say, however, that the members present were in full sympathy with the objects advocated in your article; but in this district we are faced with several difficulties, the most important being the shortage of labour. This is being severely felt, both in large and small gardens, so that the tendency is rather to reduce the area under cultivation instead of increasing it.—C. S. FUIDGE (Secretary), *Souhampton Royal Horticultural Society*.

—I placed your article before our committee on February 23, and your suggestions received the approval of the committee. Our society received, last August or September, leaflets from the Royal Horticultural Society, advising the cultivation of more vegetables, also giving a list of what seeds to sow at once. The leaflets were distributed in our neighbourhood. On December 6 last we also received a letter from Admiral Lord Charles Beresford, President of the Vegetable Products Committee, asking our society to form a local branch of the above, which we have done. Since then we have sent packages of fruit and vegetables every week to the Fleet at sea. At the annual meeting, held in January last, it was unanimously decided to hold our show in July next. I might add that Budleigh Salterton has only a population of 2,000.—E. J. VICKERY (Hon. Secretary), *Budleigh Salterton Horticultural Society*.

—In case our secretary does not think to send you another line, you may like to know that the Mayor of this Borough (Hornsey) is giving special prizes this year to cottagers and allotment holders for the best stocked and cropped garden of vegetables and fruits. This seems such an excellent idea that it is worthy of being made widely known, in the hope that other public officials might do something similar, thereby inducing extra attention to be given in the producing of necessary foodstuffs. The Mayor of Hornsey thinks that horticultural shows ought certainly to be held this year, and that fruits and vegetables should be the strong features at such shows, flowers taking a less honoured position for this year. I write as a member of the committee.—C. TURNER, *Highgate*.

Orange Marmalade : A Good and Economical Recipe.—Ingredients: Twelve to fifteen Seville Oranges (fifteen small are better than twelve large), 10 lb. of sugar, and 10 pints of water. Method: First carefully wipe the Oranges clean with a soft piece of old linen dipped in tepid water. (You cannot tell how many hands the Oranges have passed through between the tree and your

kitchen.) Cut the Oranges very thinly, remove and crush the pips, put the pips into a cup with sufficient water to cover them, and leave them to soak. Put the Oranges into the preserving pan with the water, leave them twelve hours to soak. Then boil for an hour and a-half after it boils up. Now add the sugar and boil for another hour and a-half (or longer) till it sets, when add the water strained from the pips. I have taken this recipe from my manuscript book.—ANNE AMATEUR.

Sarcococca humilis and S. ruscifolia.—The writer of this note on these plants in THE GARDEN of February 20 pays them no more than their due, but he omits to mention not the least of their virtues—the possession of an abundant crop of red berries about the size of those on a Thorn tree. The raceme has usually three male flowers, and the single female blossom at the base, close into the axil of the leaf, produces a berry, and these fringe the whole length of the spray, making the plant very ornamental till after Christmas.—ARCHIBALD BUCHAN-HEPBURN.

Hybrid Freesias.—Now that there are so many named varieties of Freesias, the cross-breeding of them is an increasingly delightful pastime. A careful study of seedlings flowering now, with a recorded pedigree to refer to, reveals one or two interesting points, as follows: *F. refracta alba* (the pure all-white species), when crossed with the coloured varieties, gives practically all self-coloured seedlings in charming delicate shades of mauve, lavender, heliotrope, salmon and yellow, according to the variety of pollen parent used; while *F. refracta* in almost all cases passes its yellow blotch on to its progeny in more or less accentuated form. One of the surprises is that in crossing a white and a pale lavender, such as *Amethyst*, a purple appears here and there; but the explanation is simple, as it is no doubt the colour of one of *Amethyst's* parents coming out in the third generation.—F. HERBERT CHAPMAN.

Division of the Leedsii Class of Daffodils.—I have for some time thought that some further division is desirable. I suggest that the solution of the difficulty as to small and large cupped *Leedsii* being shown together and the better understanding of descriptions could be met on similar lines to those adopted in the present Classification in the case of distinguishing between an *incomparabilis* and a *Barrii*, viz., the measurement of the cup or eye. Division IV., *Leedsii*, would then have two divisions, (a) cup or crown not less than one-third, but less than equal to the length of the perianth segments; (b) cup or crown less than one-third the length of the perianth segments. These divisions will, I think, suffice for the present, but within a few years a further division may be found desirable in regard to colour, and possibly still further as to size and shape of cup or crown; but "sufficient for the day is the evil thereof."—C. LEMESLE ADAMS.

Shows, Schedules and Judges.—I think it would be a great boon to exhibitors from a distance if the committee would do a little more in the way of packing and despatching boxes and stands after the show. In drawing up the schedule a clear definition of an amateur should be given. Each district seems to have a different ruling on this point. In some county agricultural shows I have seen a lot of unpleasantness through this. If there is one word in horticulture that wants settling it is "amateur." I think the fairest way is to put classes in for large and small

growers and strictly adhere to the wording of the schedule. The man with 200 Roses does not stand a chance with the amateur with 5,000. Now for the question of judges. "Exhibitor" is quite right, in my opinion, that many judges are selected because they hold a position in some large establishment, and probably have never exhibited in their lives. But on principle I would sooner such a man judge my exhibit—providing he did not enter the exhibition till all the staging was finished and the exhibitors cleared out—than the so-called expert who had, say, been staging in Classes 8, 10 and 12, and then put his coat on to judge Classes 9, 11 and 13 at a Sweet Pea show. Selecting judges from the exhibitors is simply a farce. Again, take a raiser and distributor of new varieties of anything, and then ask him to judge six new varieties sent out in the autumn of 1914 or the spring of 1915, and if there is keen competition—he can be honesty itself—he will lean to his own varieties.—FAIRNESS.

The Double Chamomile.—In a recent number of THE GARDEN a correspondent enquired about double Chamomile, and in a later issue another offered Chamomile which came up freely in her garden. It may be well to draw attention to the very common confusion between true or common Chamomile (*Anthemis nobilis*), and Feverfew, which is also called wild Chamomile (*Pyrethrum parthenium*). The medicinal plant is *Anthemis nobilis*, both single and double. The single has the greater medicinal value, though the double is the more generally grown for sale, probably because the dried bloom bulks more largely. Feverfew or wild Chamomile is a frequent garden weed, though it is good enough to be considered a garden plant. There are, I believe, some specially fine named garden forms which I do not possess, but should be glad to hear about. The common Feverfew grows about two feet high, with spreading heads of white flowers and tufts of pale green leaves that are always a welcome sight in the spring. The whole plant, and the leaves especially, have a strong, wholesome, Tansy-like smell. *Pyrethrum parthenium aureum*, the well-known Golden Feather, except for its dwarf habit, is so much like the common Feverfew that one is surprised that botanists distinguish them as separate species. I offer this note thinking that if the first correspondent was asking for true Chamomile and the second was offering Feverfew, the right plant would not be changing hands.—G. JEKYLL.

The New Zealand Flax.—In the issue of THE GARDEN for January 30, page 50, Mr. J. Beadle, Dunedin, New Zealand, discusses the question of soil suitable for the plant in its native habitat, and cites cases which have come under his own observation to prove that this plant will thrive in soils of widely differing character. This opinion agrees with what I have myself seen of the plant in the British Isles. Some ten years ago I visited the gardens at Kylemore Castle, County Galway, and there I saw this plant growing to perfection. In the mixed flower garden it was growing in huge clumps in light, friable loam, and outside the grounds there were acres of it growing most luxuriantly, in rather peaty soil, among rough grass, with no shelter whatever. In the Royal Botanic Gardens, Edinburgh, a colony of the New Zealand Flax grows well and flowers freely on a bank in close proximity to the lake; and here on the shores of the Forth it does very well in a rather dry situation, almost close up against a thicket of tall forest trees.—CHARLES COMFORT, *Midlothian*.

Centaurea (Ætheopappus) pulcherrima.—The *Centaurea* family is a very large one, and for the purpose of classification is split up into several sections. The plant here illustrated belongs to the *Ætheopappus* section, and is thus sometimes known as *Æ. pulcherrimus*. It is a very handsome species, of dwarf, bushy habit, growing about two feet high, with silvery pinnate foliage and large rosy-coloured flowers of the Sweet Sultan type. Closely allied to the better-known *C. dealbata*, but of more rigid habit and with larger flowers, it is also a native of Asia Minor and the Caucasus. An excellent border plant, of free growth and very floriferous, *C. pulcherrima* of recent introduction, and a welcome addition to a family which already provides our gardens with several handsome subjects. It may be increased by division in the autumn or spring, or may be raised by means of seeds, which are produced in fair quantity.—W. I.

Cultivation of *Tropæolum speciosum*.—That this plant will flourish in the soft, humid climates of Scotland, the Lake District and Cornwall none will doubt, but it may surprise many to know it will also not only grow, but flourish in the hot, sandy soil of Surrey if given suitable conditions. In those parts of my garden where it is established it is growing as freely as a weed. On one occasion I had to throw away nearly a barrow-load of roots. Having grown the plant with success for ten years under apparently unfavourable conditions, and having tried to study its requirements, I believe your correspondent Mr. Rowland A. Earp comes very near the mark when he says he "would plant it under the tiles of the backyard in a sunny part." As regards soil, it should contain a very large proportion of leaf-soil or peat, or both, in which the roots can spread where they please. I believe the doctors advise us to keep our feet warm and our heads cool. Well, *Tropæolum speciosum* requires exactly the opposite to keep it in good health. It flourishes in full sun, but the sun must not shine upon its roots. Plant it among the roots of *Rhododendrons*, *Azaleas*, *Kalmias*, *Hollies*, *O'ëaria*, *Skimmia* and such like shrubs, and it will send its roots right under them and wreath their tops all the summer with its lovely trails of bloom. Never must spade or fork, or even hoe, come near its sacred haunts. Nothing but hand-weeding must be allowed. If weeds appear and the *Tropæolum* runs up and over them, they must be left or snipped off. Small twigs should be put to the tender trails when they appear, so that they do not straggle over the soil. A thick dressing of leaf-soil should be given—not, I think, in the summer, as one of your correspondents advises, but in early spring before the sun has any power. Another point is not to cut the trails off in the autumn, but leave them to die back naturally. I have known some trails to remain green all the winter and start into growth in the spring, and so flower very early; but this is unusual. Of course, plant the roots deeply—8 inches to 10 inches. Never disturb them; they need a year or two to establish themselves. Let the situation be such that they can spread about in the bed among the roots of

other plants which are never dug up. If I write dogmatically, I hope I shall be pardoned, being conscious of many humiliating failures with other plants if successful with this one.—C. G. B.

—In the article on *Tropæolum speciosum* in your issue of the 6th ult., page 68, your correspondent omits one important consideration in planting the soft, long roots; that is, they should be laid on some very hard ground so that the weight of the soil overhead will not bruise the tender roots and make them decay instead of grow. That is one secret about establishing a colony of this most desirable climber, and it stands to reason it must be severely let alone. It will come up, perhaps a yard from where the planting was originally made; but wherever it comes it is decidedly welcome. With me it often lives overground all the winter, the spring growth commencing 4 feet to 6 feet up the old growth of the preceding year. One can never say for certain which aspect suits it best, but half shade and moisture are its chief

CENTAUREA PULCHERRIMA, A COMPARATIVELY NEW HARDY PLANT WITH ROSE-COLOURED FLOWERS.

delights.—J. HILL POE, D.L. (Captain), *Riverston, Nenagh*.

Undesirable Plants in the Rock Garden.—"E. H. J." in *THE GARDEN* of February 13, page 77, initiates a very useful campaign. While some of the plants he mentions hardly require a warning, so universally are their evil habits known, there are others that are easily eliminated or controlled, such as *Cerastiums*, *Hieraciums* and *Muscari*. *Sedum spurium* has never given me any trouble. *Oxalis corniculata*, once established in the rockery, cannot be banished, and seedlings appear among one's most cherished plants. The following are some of the plants the introduction of which into the rockery is to be avoided: All *Acenas*, *Cotulas*, some *Asters*, most *Vicias*, *Centaurea montana*, and *Linaria hepaticifolia*, a nice, harmless-looking plant, probably recommended by the nurseryman as most suitable to a confiding beginner; but let him beware. For a year perhaps he delights in a neat little plant with desirable leaves and flowers; he little knows what is going on underground. Suddenly a single leaf appears unnoticed in a neighbouring plant.

At last his attention is drawn to the leaves cropping up in all directions; then he digs up the long white, thread-like roots. Should he pursue his investigations, he will find the rocks beneath the soil literally encased in a coating of white roots, the most minute particle of which will grow into a plant. I have taken down a portion of rockery, removed all stones and earth three times, and yet the *Linaria* still survives. *L. pallida* is nearly as bad. The genus is saved by the three varieties of *L. alpina*, which are joys for ever. The *Vetches* and *Lathyrus* are to be viewed doubtfully. *Arenaria balearica* can become very troublesome, but must not be omitted from the rockery, notwithstanding. *Tropæolum speciosum*, once established, can never be got rid of, and spreads far and wide. For those who may desire to grow some of the undesirables on account of their beauty, either in the rockery or in the borders, a good plan is to grow them in short clay or earthenware tubes that are closed at one end; these can be obtained in various sizes. The pot is sunk sufficiently

to hide the rim, and the plant has no opportunity of spreading except over the rim. A little care will easily prevent this. I hope others will add to the list of undesirables.—ARCHIBALD BUCHAN-HEPBURN.

FORTHCOMING EVENTS.

March 9.—Royal Horticultural Society's Show of Forced Spring Bulbs, 1 p.m. to 6 p.m. Lecture at 3 p.m. by Mr. Leonard G. Sutton on "Flowers from Seed, in the Greenhouse and in the Open Border." Royal Horticultural Hall, Vincent Square, Westminster.

March 10.—Royal Horticultural Society's Show of Forced Spring Bulbs, 10 a.m. to 6 p.m. Royal Horticultural Hall, Vincent Square, Westminster.

March 16.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1 p.m. to 6 p.m. Lecture at 3 p.m. by the Rev. Professor G. Henslow, M.A., V.M.H., on "The Passing of Darwinism." Royal Horticultural Hall, Vincent Square, Westminster.

BEAUTIFUL GREENHOUSE PLANTS.

THE BRUNSFELSIAS.

A GENERATION ago the Brunsfelsias were far more frequently grown in gardens than they are at the present day. Though the above generic name has been long used by botanists, the different kinds were almost invariably known as Franciscias, which is in gardens and nurseries still retained. Some of the species, notably *B. calycina*, represented by different forms to which specific names used at one time to be applied, was, and still is, the most generally grown of them all.

In the variety *grandiflora* the flowers, which are fully 3 inches across, are, when first expanded, of an intense purple colour, but gradually pale till they become almost white. This is common to most members of the genus and forms a very notable feature, as, in the case of a large, well-flowered specimen, blossoms of all shades of colour from purple to white may be seen on the same plant. A dwarf, compact-flowered form of *B. calycina*, with the varietal name of *floribunda*, has been brought prominently forward within the last few years. As good examples full of bloom may be had in pots 5 inches in diameter, it is invaluable for various decorative purposes where the larger growers would occupy too much space.

A good, large-flowered variety of *B. calycina* known as *confertiflora*, and which used to be assigned specific rank, is of particularly good habit, which circumstance stood it in good stead when specimen plants were popular. There are several other species of which especial mention may be made, namely, *B. hopeana* or *uniflora*, a dwarf, compact little bush with small leaves and solitary violet purple flowers with a light centre. The species herewith illustrated—*B. undulata*—has flowers white or nearly so. It is a native of Jamaica, whence it was introduced as long ago as 1780. It does not, however, appear to be in general cultivation in this country, for I cannot find it mentioned in any catalogue, neither is it in the "Kew Hand List." All the members of this genus, which belongs to the Order Solanaceæ, are natives of the New World, mostly from the West Indian Islands or South America.

The different Brunsfelsias require the temperature of a stove for their successful culture, at all events during the greater part of the year, for when growth

is completed they are benefited by being removed to the coolest part of that structure. A mixture of loam, peat and sand suits them well. Propagation is readily effected by cuttings of the young growing shoots taken in spring and put in a close propagating-case with a gentle bottom-heat. Shade is essential to the well-doing of the Brunsfelsias, particularly during the flowering period, as the blossoms last much longer when protected in this way. Most of the kinds flower during the latter part of the spring, and maintain a succession from then till summer is well advanced. One

ROSE-GROWING IN TOWN GARDENS.

SOME NOTES ON MANURES AND THEIR EFFECTS.

IT can hardly be over-emphasised that, in applying stimulants of any kind to Roses, the greatest care should be taken not to overdose them. Plants can only take up their food in liquid form as it becomes available for the roots by decomposition or other chemical change, and the amount that they are able to assimilate depends largely upon the health of the trees and the condition of the soil. Too strong a stimulant frequently destroys the feeding roots, and can have nothing but harmful results, so that growers should be careful never to apply any artificial manure in greater strength than is recommended from some reliable source.

But before attempting to enrich the soil in this way, the texture and quality of the beds should be improved by methods which have been indicated; then, when the ground is in "good heart" and the plants growing freely, one may have recourse to the aid of certain artificial manures, which will add materially to one's success.

To be of real benefit, a fertiliser must contain fair proportions of those elements most needed in the soil, either because they are more quickly exhausted by the growing plants or the ground is naturally deficient in them. To add these intelligently and to know exactly what one is adding is the only method by which one can make sure of the effect they will have upon the plants; so that a consideration of the manures most generally in use may be of advantage to those who are unfamiliar with their character. Certain of these are natural, others contain the elements in concentrated form; but for convenience they are here classed together.

The principal soil elements in relation to the Rose are nitrogen, potash, phosphates, lime, iron and magnesia.

The first three are those most freely taken up, the others needing to be added only when there is a deficiency. Obviously one can do little good by administering lime to chalky ground, or iron where there is already an abundance of it, so that a general formula needs to be modified in accordance with the local conditions, and this is another reason for learning something about the manures before applying them.

Nitrogen may be briefly regarded as the principal element which gives vitality to the plant. Its addition to the soil promotes quick growth, but it must not be given unless a sufficiency of

BRUNSFELSIA UNDULATA, A NATIVE OF JAMAICA, WITH WHITE FLOWERS. IT NEEDS A VERY WARM GREENHOUSE.

would like to see these plants more widely cultivated than they are at present. H. P.

SKIMMIAS IN PERFECTION.

In the rock garden in the Royal Botanic Garden, Edinburgh, I recently saw the two finest clumps of Skimmias it has ever been my lot to behold, so healthy and so completely smothered with berries of the brightest red. Much confusion prevails in the nomenclature of the Skimmias; but the two clumps in question were labelled *S. oblata* and *S. Fortunei*. C. C.

phosphates or potash is already present. Some nitrogenous manures, such as sulphate of ammonia, are very quick in action, so that the application of the other elements should take place well in advance of it. Excess of nitrogen will benefit the foliage at the expense of the bloom; the want of it is usually indicated by pale green foliage, the plants having a stunted appearance and lacking vigour.

The principal forms used by the Rose-grower are nitrate of potash, sulphate of ammonia, dried blood and hoof and horn. The last two are slow in action. Horn-meal is useful for adding to Rose beds when making them up, and is very lasting in its effects.

Dried blood contains potash, phosphates, iron, magnesia and lime in small quantities in addition to the nitrogen, so that it makes a valuable stimulant.

Apply 2oz. to the square yard in early spring. Nitrate of potash (saltpetre) contains both the substances its name implies, but it is rather expensive, and as the proportion of nitrogen is very high, it is only safe to give it in a very diluted form; a quarter of an ounce to a gallon of water is quite strong enough.

Sulphate of ammonia is a well known and valued stimulant of great assistance to exhibitors when applied carefully. It dissolves very readily in water, to which it should be added in the proportion of an eggcupful to four gallons, giving each plant a gallon of the liquid. This should be applied only to vigorous trees when the beds are moist and after the buds have formed. The nitrates of soda and ammonia are also concentrated forms, but the substances previously named are much to be preferred. P. L. GODDARD.

(To be continued.)

THE MUSK ROSE (ROSA MOSCHATA).

This delightful species should find a place in every garden where space can be allotted for its very vigorous growths. It is best seen growing as a big free bush, well isolated, or rambling over a clump of tree stumps placed in a conical form in any odd corner. It is a most profuse blooming Rose when well established, but is liable to suffer in a severe winter; hence the need for a rather sheltered spot. The flowers appear about the first week in July, and continue in great beauty two or three weeks. It is really one of the wild Indian Roses, *R. Brunonii*, which is sometimes known as the Himalayan Briar, being a form of it. The variety *grandiflora* is perhaps the most rampant-growing rambler one can obtain, and it will ascend to the top of a tree before any other Rose is half-way up.

DANECROFT.

DAFFODIL NOTES.

The English Name.—It seems almost incredible, but I know a man somewhere about twenty-three or twenty-four years of age who did not know his proper Christian name until twelve months ago! There are many who do not know what to call the Daffodil family. At one time it is Daffodil and at another Narcissus. Suppose for one moment these plants were human beings and that they had visiting cards, what would the different branches print upon theirs? Would it be Mr. and Mrs. Narcissus, or Mr. and Mrs. Poetic Daffodil, if they used an archaic form, or Mr. and Mrs. Poet Daffodil if they preferred a more modern one? I am frequently asked

My thoughts have been directed into this channel by reading an address that old Peter Barr gave to the Sea Point Horticultural Society at Cape Town in 1901, in the course of his famous tour round the world. He recalled the time of the first Daffodil Conference in 1884, when he said "the subject of a popular name was much debated." He tells us that ultimately it was decided to adopt Daffodil for all sections of the family. And then in accordance with this he writes in the concluding paragraph of the introduction, "In this paper the word Daffodil will be used throughout, except when a quotation is made, and then the words of the author will be given."

The family name is still, I fear, in what chemists call the unstable equilibrium, and from the loose

A NOBLE BUSH OF THE MUSK ROSE (ROSA MOSCHATA).

by non-Daffodil people what the difference is between a Daffodil and a Narcissus. The proper reply is "None." Daffodil is the English family name and Narcissus the botanical or Latin one. Every Daffodil is a Narcissus and every Narcissus is a Daffodil, and in Parkinson's day (1629) was called one. In course of time the names got jumbled up, and some people used Daffodil and some Narcissus, or quite likely first one and then the other. In the sixth edition of "Miller's Gardeners' Dictionary" (1752) all branches of the family, with the exception of the Jonquils and Tazettas, were Daffodils; whereas in 1771 John Dicks, in his "Gardeners' Dictionary," called them all Narcissus. So it has continued up to the present.

way in which we use the words Daffodil and Narcissus it must be difficult for the various branches to know exactly what to call themselves among their English friends.

My purpose in these remarks is to plead for the retention and use of the old word Daffodil when we write or speak of the different sections. This practice would be in strict conformity with the nomenclature laid down by Parkinson, approved by the 1884 Conference, and recommended by our king (Peter Barr). I may add that in Hill's edition of "Hale's Eden" (1757) we find the "Poetic Daffodil" (*sic*) described and figured. It is interesting to record the use of the actual designation for our "Poets," that I would like to see generally adopted. Taking the garden classification

of the Royal Horticultural Society (1910), I would venture to suggest the following English designations for the different classes:

1. Trumpet Daffodils.
2. Incomparabilis or large-cupped Daffodils.
3. Barrii or small-cupped Daffodils.
4. Leedsii or white-cupped Daffodils.
5. Triandrus or Angels' Tears Daffodils.
6. Cyclamineus or Cyclamen-flowered Daffodils.
7. Jonquilla or Rush-leaved Daffodils.
8. Tazetta or bunch-flowered Daffodils.
9. Poeticus or Poet (Poetic) Daffodils.
10. Double Daffodils.
11. Various Daffodils.

In order to try to arrive at a general agreement, it would be of much interest if those concerned would state their views; for example, Mr. P. R. Barr. My friend, I notice, has lately altered his signature. It is now Peter R. Barr, and not the more familiar P. Rudolph Barr of his younger days. I am not surprised at the change. It is only the Daffodil blood coming out! He is a true "chip of the old block."

Poet Daffodil Classes.

Begin to repair an old house, and you never know where you will stop. My note about the necessity of show committees seeing that all blooms were exhibited in their proper classes has brought me a plaintive note from one of my "Poetic" friends. He sees the Poets so frequently wrongly named, more particularly in the amateur and smaller classes, that he thinks something ought to be done. I agree. Will he, however, suggest the remedy? Not a great while since I wanted to get an old variety named. I took it to Birmingham, but I could not find anyone who would stake "his bottom dollar" upon it. The fact is that if we exclude a comparatively few well-differentiated varieties, Poet Daffodils are *very much* alike indeed, and I think nine hundred and ninety nine people out of a thousand would soon get out of their depth if called upon to name by the eye and memory alone. Much as I value correct naming, I feel there is a good deal of excuse to be made for those who err here, and that an unintentional wrong label is but a venial fault. "My teeth is it that won't let me pass, then?" said the Irishman to the recruiting doctor. "Faith, sure, my cousin Mike got through with the same ones only last week!" It might so easily be right at London, wrong at Birmingham.

The Day.—"The Day" for the Daffodil enthusiast is the official opening of the season, which is heralded by the first meeting of the Royal Horticultural Society's Narcissus committee and the holding of the Forced Bulb Show at Vincent Square. This year it is March 9. A letter from Mr. Daffodil Pearson (the three brothers have such convenient initials) tells me how he had all his soil sterilised in the autumn before potting any

Horticultural Society's powers that he combine a still earlier exhibition with that rather woe-begone function the annual general meeting? It seems to want something to make it "go."

Royal Horticultural Society's List of Daffodil Names.—I have had the first instalment of the "six hundred thousand" from Mr. Curtis since my last notes appeared. We are getting on—between three hundred and four hundred is not a bad start. J. J.

EVERGREENS ON WALLS IN WINTER.

It is only in the depth of winter that we fully appreciate the value of evergreen shrubs and trees. In woodland, in the colder months, there is often nothing green but Holly and Ivy. It is then that we see what precious things are these two native evergreens; not only beautiful in themselves, but giving evidence of comfortable harbourage to many forms of wild life. So also in gardens, the shrubs with persistent foliage, that in summer passed almost without notice, acquire their full value in winter, and are then in their richest dress.

In planting garden spaces against buildings the mistake is often made of having borders of temporary or summer plants only, especially in such places as narrow borders between house wall and terrace walk; but if these are filled with evergreens, such as Laurustinus, Rosemary, Lavender and Berberis, with, among them, a few points of interest as of China Rose and Lilies, there is a pleasant sense of permanence and a kind of dignity that is in harmony with the sentiment of a good building. When a garden is

THE JERUSALEM SAGE (PHLOMIS FRUTICOSA) IN WINTER. THIS IS A BEAUTIFUL GREY-LEAVED SHRUB.

bulbs, and that this precaution has had the happiest results, so I presume he hopes to show us "what's what" next week. He is, I believe, "the father" of competitive exhibitors, his first essay at Birmingham going back to almost prehistoric times. I should very much like to see him carry off a gold medal on March 9. There are plenty of good fish in the sea at Lowdham. I look forward to this show with increasing interest each year. It has already proved the elasticity of the Daffodil season, but it will bear a little more stretching. Why should not the Royal

terraced, and there are retaining walls of solid masonry at the back of borders, the good use of evergreen shrubs is important, not only for their own display, but for winter clothing and as a background to the flowery masses of summer. There are many more shrubs suitable for such places than are generally thought of. Where walls are fairly high, there are such fine things as the evergreen Magnolias and Bay (no matter if they rise above the wall level), Myrtle, Azara and white Jasmine, for though Jasmine is not strictly evergreen, not only does it hold its leaves

till Christmas, but the mass of green stem shows with a general green effect. Some climbing Roses have the same quality; Jersey Beauty is now (late in January) not only well clothed with its polished foliage, but is bearing such quantities of red hips in thickish bunches that its whole effect is highly ornamental. Reine Olga, that good red Rose that makes yearly growths 12 feet to 15 feet long, will be in fine foliage through February and even later. Garden Ivies are only too numerous, but the very large-leaved *Hedera dentata* and the small marbled *Caenwood* variety are so distinct that they should not be forgotten. *Cistus cyprius* is a fine thing on a fairly high wall, its fragrant foliage turning strangely blue in winter. Shrubs with variegated leaves should be used with caution, to avoid the danger of a

and is much benefited by being trained on a wall with a warm exposure. They are quite vigorous enough for high walls, but are perhaps better seen on those of lesser height. *Garrya elliptica*, with its pretty tassels of midwinter bloom, is also suitable for high or lower walls. Myrtles, in warmest places, should not be forgotten, and the handsome Box, *Buxus balearica*. *Escallonia macrantha* and *E. philippiana* are both beautiful on walls, the latter flowering in late summer when shrub bloom is rare. *Choisya ternata* is one of the best of wall shrubs, and Rosemary, often seen on walls in Italy, should be so used at home. The grey, Sage-like foliage of *Phlomis fruticosa*, a shrub commonly grown as a bush in the open, is capital trained, and still better is the beautiful grey-leaved shrubby Groundsel, *Senecio Grayii*.

Its tiny gold-backed leaves, set on long sprays that quickly grow, make it one of the prettiest things to cut and put with winter flowers in the house. Even *Berberis Aquifolium*, so useful and frequent as a bush in every garden, can be trained on a low wall with singularly good effect.

GERTRUDE JEKYLL, in *Country Life*.

HERBACEOUS PHLOXES FOR SPRING PLANTING.

THERE is such a wonderful wealth of beauty and variety to be found among the modern herbaceous Phloxes that it is not surprising their cultivation is being taken up in many gardens where,

A BORDER OF HERBACEOUS PHLOXES AND WATSONIAS. BOTH MAY BE PLANTED NOW.

patchy effect; but where questions of colour are carefully considered and a harmonious background for flowers of bright yellow colouring is desired, it is well to train on the wall both the gold-splashed *Elæagnus* and the Golden Privet.

Walls from 5 feet to 7 feet high will take shrubs of medium height. One of the best is *Laurustinus*, excellent for wall training and yet but seldom used. All the three varieties well known in gardens are equally suitable, but of special beauty is the May-blooming *Viburnum lucidum*. It is tenderer than the two other kinds, *V. Tinus* and *V. hirtum*,

For lower walls there is still a good choice of evergreen covering, such as several of the lesser New Zealand Veronicas. The taller *Veronica Traversii* is of a size for the wall of medium height, but there is a dwarfer variety of this well suited for the lower terrace. Other New Zealanders, *Olearia Haastii*, *O. stellulata* and *O. macrodonta*, will also be welcome; several kinds of *Cotoneaster*, *Euonymus radicans* and *Daphne pontica*, the last filling the garden with its sweet scent in April and May. *Aucubas* can be used in shady places, and *Cassinia fulvida* must not be overlooked.

a few years ago, they were unknown. Flowering as they do in the autumn, when many wish gardens to be at their best, these Phloxes may be looked upon as the most useful of all herbaceous plants for that season. Their cultivation, too, is simple, providing a few essential points in the tilling of the soil and their subsequent treatment are not overlooked. Above all, these Phloxes need a generous diet, with deeply cultivated soil in which their roots can wander at will and find that coolness which they so delight in during the scorching days of summer. But

coolness of roots must not be taken to mean overhead shade from sun.

The first object, then, when we set out to grow these plants is to select a bed or border that is open to light, free from roots of trees or shrubs, and containing soil that is of good heart, *i.e.*, not too much sand or gravel. This ought to be dug two spits deep, and both spits should have thoroughly mixed with them some partially decayed manure from either the stables or farmyard. After this trenching it ought to be made moderately firm by treading, unless it can be allowed two or three weeks in which to settle before planting is done. Undoubtedly the best time for planting, except where the soil is of very close texture, is early autumn, but quite good results can be obtained from plants that are put in during March. Young plants raised from cuttings are supplied by most nurserymen, and

Jenkins, Tapis Blanc and F. G. von Lassburg (white), Le Mahdi (violet blue), Eugénie Danzavilliers (soft lilac blue), Le Siècle (salmon pink), Etna (crimson scarlet), Paul Martin (china rose), Dr. Königshofer (brilliant orange scarlet, deeper eye), Baron von Dedem (scarlet and blood red) and Selma (pink).

H.

PROPAGATING PLANTS BY CUTTINGS.

THE importance, particularly at this period of the year, of propagation by means of cuttings induces me to send you the following remarks as a further contribution to the discussion on "Cuttings with 'Heels.'" The "heel" to cuttings is in certain instances not without value.

taking place, almost the whole of the soft-wooded material forms roots without even providing the cutting with the time-honoured "joint." It is an asset of value to know, for it takes a longer time to trim such a cutting preparatory to inserting it in its rooting medium than the time occupied in cutting the shoot above a joint and inserting it.

But the method has a further value. To illustrate: Last year I required a very large quantity of *Verbena venosa*, and to supplement old roots some 600 plants were raised from seeds, which it was seen would be very insufficient. These were forced on, and when just large enough were cut off close above the pair of primary leaves. If the cuttings had been made with a joint, time would have failed to have got a plant large enough to allow for it to grow, and to strike and grow on the rooted cutting.

A cutting to root rapidly and with certainty, as already hinted, must be in a proper condition, and also receive the proper treatment. Heat and moisture are enough for the majority of bedding plants at this time of the year, and even Geraniums, if they receive a Pine stove heat, root readily with abundance of water, while, given an intermediate temperature, moisture may prove fatal to success. Hollyhocks are difficult to root in the spring, but when named varieties were in vogue I have succeeded by placing them under hand-lights in a cool house, where they took their own time. The Variegated Ice Plant will root with the loss of only two or three per thousand when placed in a stove temperature and given no water till roots have been formed. Nor need the cuttings have joints.

The success of a batch of cuttings may be destroyed by allowing them to wilt; and it is not unusual to see a man make elaborate preparations from his point of view to ensure success, and, by allowing the cuttings to get dry previous to insertion in the rooting medium, to nullify his labour. Eye cuttings during the summer months are valuable means of increasing such things as Hollyhocks, *Lychnis vespertina* flore pleno, double Rockets and other plants of similar herbaceous habit. Christmas Roses may be increased in the same way, with the difference that it is the rootstock that must be cut up, each piece to be provided with one or more "eyes."

This method has been known in Scotland for very many years.

R. P. BROTHERSTON.

A BORDER OF PHLOXES EDGED WITH ORDINARY WHITE PINKS IN A SMALL GARDEN.

usually give better results than divided portions. I am a great believer in mulching Phloxes during the hot days of summer, and towards the end of May always see to it that a layer of short manure, at least 2 inches thick, is spread between and around the plants. This not only tends to keep the soil cool, but provides considerable nourishment for the plants just when they most require it. Bountiful supplies of water are called for whenever the weather is at all dry, and it is vital that the Phloxes are not neglected in this respect. These, then, are the essential points in the cultivation of these charming hardy herbaceous plants, which are suitable either for large or small gardens, as the accompanying illustrations show. In the large border Watsonias are thinly interspersed among the Phloxes, and the bulbs of these may be planted during March or April.

There are a great many beautiful Phloxes now obtainable, a few of the best being Mrs. E. H.

Some Roses that will not root when the cutting is made by severing below a joint do so when formed with a "heel." But there is a chance of a "heel" cutting forming merely some knobby calluses, due not so much to the "heel" as to some condition of the cutting or the position it occupies.

Far better than using hardened wood for cuttings is to employ young shoots that are becoming firm but not too hard, the proper condition being only possible to determine by observation and experience. I have rooted quantities of such things as Deutzias, Lilacs, Roses, Buddleias, Philadelphuses and such like in this way in a heated propagating-case. A single white Banksian Rose put into my hands a few years ago to increase was found to root with the greatest facility from soft summer side shoots, when ripened wood in the autumn failed.

Summer Bedding Plants.—At the present time, when propagating for summer bedding is

COLOUR CHARTS: WHAT IS WANTED.

THERE are probably few people who garden who have not had rude shocks and awakenings when, for the first time, they have been face to face with stern reality, and the insinuating catalogue descriptions upon which plants or seeds were bought, and upon which visions of loveliness were built, have been found to be sadly wrong and misleading. Glowing adjectives and wonderful colour names, skilfully chosen, have more than once furnished up some rather mediocre bloom that it has acquired in our eyes a distinction which its intrinsic merits

we see with their eyes, and if we are not able to do so it is not wholly their fault. It is the fundamental difficulty of not being in another's skin that causes so much confusion. Where would we be without a standard yard or a standard pound? I think, where Moses was when the light went out. Civilly, we would not like it at all; horticulturally, we do not seem to mind very much. Few use what means there are at hand to remedy this. It may be, of course, because they are unknown, or it may be because the remedy appears as bad as the disease. No colour chart that has yet appeared is *quite satisfactory*. Attempts, however, have been made to meet this need of the gardener—to give him, in other words, a standard, so that a Regel in Russia, a Mrs. Frances King in America and a Miss Jekyll in England would know exactly the shade of rose (?) of Krelage's beautiful new Tulip Siren, which took us all by storm on its first appearance last spring.

The bibliography of horticultural colour charts is a short one. The first attempt seems to have been made by the editor of the *American Florist*, who issued, as a supplement to the issue of that journal for August 17, 1895, "A Chart of Correct Colors of Flowers," arranged by F. Schuyler Mathews for the use of florists. I have it before me as I write. It is a single sheet, 12 inches long by 8½ inches wide, and contains thirty-six distinct shades. Some years later Mr. A. Blanc of Philadelphia issued a "Colour Guide for Florists," compiled by one "A. Kohn." It contains 140 shades, which are printed on two sheets, each, roughly speaking, 12 inches by 8 inches.

Then came the "Répertoire de Couleurs," issued in 1905 under the auspices of the French Chrysanthemum Society. At the present moment it is the only one that is at all well known in England. It is undoubtedly a great production, inasmuch as it contains samples of upwards of one thousand four hundred shades, printed in blocks of 1½ inches by 1½ inches on 365 sheets. Colour names are given in English, Italian, Spanish, French and German, and a typical flower of each is indicated.

Another attempt is the "Code des Couleurs," published in Paris in 1908 by Paul Klincksieck and Th. Valette, "à l'usage des Naturalistes, Artistes, Commerçants et Industriels." Seven hundred and twenty colours are given, in twelve groups, each of which is named, while all the individual shades are simply numbered. The whole are bound in book form, which is certainly, in my opinion, far and away the most handy form in which to have a "chart." The different colours are cut out of sheets and *pasted* on the pages. I have sometimes found it useful for reference, but I do not use it as a rule. Probably I would have done so more frequently had not "Color Standards and Nomenclature," by Dr. Ridgway, Curator of the Division of Birds, United States National Museum, appeared in 1912, just when I was beginning to use a colour chart as an everyday affair. It, too, is in the form of a book (small 8vo), but instead of 720 it contains 1,115 named colours, gummed on fifty-three pages. Much labour has been spent on its production, and if only there were more variations given of certain tones (I think this is the correct word) of red, there would be little to be desired. It is handy, and the dull surface of the colouring seems more natural than the glazed one of the did not warrant. I by no means blame catalogue makers as a class. They do their best to make

"Répertoire." The fly in the ointment here is the unaccustomed names that Dr. Ridgway has given to the various hues, tints, tones and shades. I guess we must be Americans to understand them. Who can form straight off a visual image of Bradley's Blue or Niagara Green? Were it possible to simplify these and to add some more reds, there would be but little fault to find. Correspondents in the States tell me that the learned author is about to revise the present work and to bring out another, but a smaller one, for garden use, which is to contain thirty-six new colours, and which will exclude certain broken shades of greens, green-blues and greys, and also the darkest shade in each series, of which there are 159. As I have been asked to send suggestions to Dr. Ridgway, one feels that an expression of their views on the part of those interested would be of much value and use. On the principle of two heads being better than one, I hope the Editor will allow me to ask for a few words from such people. I may add that the colourings of the Tulips at the trials at Wisley are being determined by Ridgway's Chart, and that the opinion of the user pretty well coincides with my own, viz., that it wants more reds, simpler colour names, rather larger colour slips, and to be sold at a lower price.

A great deal of interest in this question of colour charts is being taken in amateur gardening circles in America. Among others, Mrs. Frances King and the Shedowa Garden Club of Garden City, Long Island, are taking up the matter with much zeal.

JOSEPH JACOB.

SPRING MANURING FOR VEGETABLE CROPS.

ANonus lies upon every cultivator of economic crops to leave nothing undone necessary to a maximum yield in the growing season now imminent. In a favourable year the most potent factor contributive to heavy yields is manure. While the average farmer or market grower is alive to this fact, there is yet a goodly percentage of the occupiers of small areas of land who do not effect the enrichment of their soil to the extent desirable. This is attributable to a variety of causes, in which monetary stringency and lack of opportunity loom large. A special endeavour is, however, now needed in the interests of all.

While it is not prudent to allow work that can be done in the winter to encroach unduly upon a very active period in gardening, there are yet many good reasons for deferring manuring until now. The avoidance of loss of plant food contingent upon winter manuring is not one of the least of these. Of the phosphatic manures, basic slag may still be used at the rate of 2oz. to 4oz. per square yard for such late-maturing vegetables as Kidney and Runner Beans, late Peas, Turnips and summer-planted Brassica. Superphosphate is, however, the best form of phosphate for present use. It may be sown in the drills for Potatoes, Peas and Beans, but where crops needing shallow drills are concerned, the "super" is better sown broadcast. The quantity to apply will depend upon the percentage of soluble phosphate the grade contains. If this ranges from 26 per cent. to 30 per cent., 2oz. to 3oz. per square yard will be sufficient; costlier grades containing 35 per cent. to 40 per cent.

will for economic reasons be used more sparingly, i.e., 1½oz. per square yard. Bone-meal is another important phosphatic manure, and relatively expensive for open ground work. Costing more than double as much as superphosphate, its application ought not to exceed three-quarters of an ounce per square yard.

Potash manures will be practically unobtainable this spring. Where fortunate circumstance finds a gardener with a reserve of sulphate or muriate of potash, this should be utilised at the rate of half an ounce to three-quarters of an ounce per square yard, on ground destined for such potash-needing crops as Potatoes, Beet, Parsnips, Carrots and Turnips. If it is kainit that is held, then apply it immediately to land intended for the later-growing crops, such as maincrop Potatoes, at the rate of 2oz. to 2½oz. per square yard.

The nitrogenous manures of an inorganic character are quickly exhausted in the soil, and it is a happy circumstance that in one form or another supplies are adequate. The exigencies of the period have in general raised the prices of manures. Nitrate of soda is, however, an exception. This is due to the large supplies that normally go to Germany being to a certain extent available for Great Britain, her Allies and neutral countries. Nitrate is very soluble, hence it is advisable to spread its application over the growing season. Three-quarters of an ounce per square yard can be applied at sowing or planting time, and a slightly reduced amount when the plants are in active growth. Such leaf and stem vegetables as Brassica, Leeks, Onions, Celery and Lettuces are very responsive to this manure. Sulphate of ammonia offers nitrogen at a less cost per cent. than that in nitrate of soda. Curtailed supplies and an increasing demand are, however, rapidly narrowing the difference. Applied now at the rate of 1oz. to 1½oz. per square yard, this manure will benefit all vegetable crops, and is particularly suitable for soils of a heavy nature and not unduly charged with lime. On lime-deficient soils nitrate of lime and calcium cyanamide will be found suitable—the former for dry and the latter for wet districts—used at the rate of 1oz. in the case of nitrate of lime and 1½oz. in the case of calcium cyanamide per square yard. Both should be applied at once.

The highest purposes of cultivation are served in maintaining the humus content of the soil by using from time to time such organic manures as are provided by the stable and farmyard. Used at the rate of from 2cwt. to 3cwt. per square pole, there is no need to resort to inorganic manures, except as supplements to support continuous cropping or substitutes when organic material is scarce. Horticulturists must not forget that rain-washing vastly depreciates the value of organic manure.

Other substances, simple and economic, that contribute to fertility are soot, used at the rate of one peck per square pole; wood-ashes, which when unwashed by rain contain almost as much potash as kainit; common salt, which, used during the growing season at 1oz. per square yard, enhances the yield of Brassica, Beet and Celery; and finely ground limestone and quicklime, both of which are essential to good tilth, neutralising of sourness and liberation of previously unavailable plant foods. Apply ground limestone at the rate of half a pound, and quicklime at a quarter of a pound per square yard.

Morpeth.

C. W. MAYHEW

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Melons.—When the leading growths have covered about two feet of trellis, they may be stopped. Those laterals which are showing fruit should be pinched at the second leaf beyond the fruit and secured neatly to the trellis. When there are two or three flowers fully developed on a plant, they must be fertilised. When it can be seen that sufficient fruits have set, all superfluous growth must be regularly removed and everything done to assist the fruits to swell freely. The plants will require more water when the fruits are swelling, and during the final stages plenty of stimulants must be afforded.

Strawberries in Pots.—Plants which are swelling their fruits must be liberally fed with manures. Liquid manure may be alternated with some approved fertiliser. Spray them with lukewarm rain-water two or three times a day till the fruits commence to colour. At this stage more air must be admitted to the house and the atmosphere kept drier.

Early Pot Vines.—When the berries have been thinned, every inducement must be given those left to swell. The roots must be more liberally fed and the temperatures well maintained. The laterals must be regularly pinched and all surplus growth removed. Do not leave more bunches than the Vines can mature perfectly. About eight bunches to a Vine should form a reasonable crop.

Plants Under Glass.

Primula obconica.—Plants of this are most useful for the greenhouse or conservatory. Seeds may now be sown for raising plants for autumn flowering. Sow in pots or shallow pans in a fine, light compost, and cover the seeds lightly with very fine soil. Place them in a warm, moist house, cover the pans with a sheet of glass, and shade them till the seedlings are through the soil.

Primula malacoides.—This is another very desirable subject for the cool greenhouse, and may be propagated now by seeds. It is very easily cultivated, but, when the flower-spikes are throwing up, water must be applied with care, as they are very liable to damp off.

Lobelia tenuior.—For summer flowering, plants may be raised from seed sown now and placed in gentle warmth. When large enough, pot the seedlings into 3-inch pots, in which size they will flower.

Statice Suworowii.—This is a useful plant for the greenhouse. Sow the seeds in shallow pans and prick the resultant seedlings into small pots. They will flower in 4½-inch pots, but they must be treated liberally, or the flowers will be weak.

Begonia Gloire de Lorraine.—If cuttings are available, a batch may be inserted now. Dibble them into pans of sandy soil and place them in the propagating-pit. In the event of cuttings being scarce, leaves may be successfully employed for propagation.

The Flower Garden.

Border Carnations.—When the ground is in suitable condition, the plants which have been wintered in cold frames may be planted out. To give the plants a good start, it is an excellent plan to put a little soil from the potting-shed with each plant. Plants which were put out last autumn should have the soil stirred about them with the hoe after dusting them with well-seasoned soot.

Hollyhocks.—Plants in pots which have been wintered in frames may now be planted out. In case of severe frost, a handful of coal-ashes placed round each plant will keep them safe. The disease which so often attacks the Hollyhock may be checked by spraying the plants with Bordeaux mixture during the early stages of growth.

Agapanthus.—Plants which have been wintered in a frost-proof shed must not be kept too dry at the roots. They should now be removed to a cool house if one is available.

Sweet-Scented Verbenas which are growing in tubs or large pots must have their annual

pruning. They may be kept in their winter quarters till growth is active.

The Rock Garden.—After the heavy rains of the past winter, the roots of many of the plants will need a little fresh soil.

The Hardy Fruit Garden.

Protection of Fruit Blossom.—Some ready means must be at hand for covering Apricots, Peaches and Plums when they are in flower. Here we place two or three thicknesses of fish-netting over the trees, and usually find this answers well. Spruce boughs carefully placed about the trees will preserve many of the flowers, but they must be firmly secured, or much damage will be done during stormy weather.

The Kitchen Garden.

Asparagus.—If new plantations are under consideration, the ground must be prepared at once if not already done. This crop requires very liberal treatment, and nothing short of trenching and well manuring the ground should be attempted. A sheltered situation which is thoroughly exposed to the sun should be selected.

Peas.—A sowing of Early Giant, Gradus or some other reliable hardy kind may be made now, and if fortnightly sowings are made from this date, a continuous supply of pods should be assured.

Broad Beans.—Another sowing of these may be made now to follow the early sown plants.

Seakale.—The roots or thongs which have been prepared for planting may be put out any time now when the ground is in condition.

Celery.—The main crop of Celery may be sown within the next fortnight. Sow thinly in a light soil in a cold frame. When the seedlings are through the soil, give them every inducement to make strong, healthy plants.

Tomatoes.—Seeds may now be sown for raising plants for growing outdoors. A free-setting variety of hardy constitution must be selected for this purpose.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Violets.—The ground where these are to be grown ought to receive a good dressing of manure when being dug. Before planting, a covering of leaf-mould should be lightly forked in near the surface, and if the soil is very stiff or heavy, the addition of some sand is an advantage. If possible, deal with the planting during the next few days. For such sorts as Marie Louise, Neapolitan and Mrs. J. J. Astor allow from 10 inches to 1 foot between the plants, while for varieties like Princess of Wales and La France 15 inches to 18 inches will be necessary.

Zonal Pelargoniums.—For winter flowering, plants must be propagated now. Cuttings can be put four or five in a 4-inch pot and kept close until rooted.

Anchusa italica.—If young plants which were raised from seed last spring were potted up during September or early October, they may be brought indoors and grown on in mild heat, as they make a very nice display in the greenhouse during April and May. The Dropmore variety and Opal are both very fine for this purpose.

Browallia speciosa major.—This is one of the finest greenhouse flowering plants, and is very easy to cultivate. Sow the seeds in heat, and when large enough prick out the seedlings two or three together in a 3½-inch pot. Later they may be potted into 5-inch and 6-inch pots, in which they will continue flowering for two or three months. This subject will also flower freely during the winter if cut back slightly during the autumn and watered with care until new growths are well advanced.

Fruit Under Glass.

Melons.—Seeds should be sown to produce plants to succeed the early batch. As mice quickly discover the newly sown seeds, precaution

must be taken against this. Sow singly in 2-inch pots and place in a case with a brisk bottom-heat. As soon as the plants appear, remove to a shelf near the glass, so as to encourage a sturdy growth. Two very reliable free-setting varieties are Hero of Lockinge and Eminence.

Vines.—Such Grapes as Muscat of Alexandria and Mrs. Pince, which require a long season of growth; should now be started by closing the houses in which they are growing, so that the berries may be allowed to colour well before the sunshine of August and September is over. A little fire-heat at night and during dull days will be sufficient until growth is visible.

The Kitchen Garden.

Turnips.—A small sowing of Turnips may be made in a warm, sheltered border; but as there is much risk yet from frost, it should be followed by another sowing, as early sowings are not to be relied upon. Both Snowball and Early Milan are good early varieties.

Onions.—The main crop should be sown as soon as the ground is in fit condition. The ground having been dug or trenched some time ago, it ought now to be raked over roughly first, removing any large stones; then be made firm by tramping, and finally raked over with a fine steel rake. The drills should then be drawn out 1 foot to 15 inches apart. After the seed is sown and covered, the ground may be made even and level by using the back of a rake.

Parsnips.—To get large roots, special preparation of the ground is necessary. The lines should be 18 inches apart, and holes made every 9 inches with a crowbar; these can be filled with some light sandy soil, and four or five seeds may then be sown on each.

Lettuce.—If seed is sown now in boxes indoors, plants will be forthcoming ready to plant outdoors towards the end of this month. The base of a wall or glass-house with a south aspect should be reserved for this crop.

The Flower Garden.

Roses.—Teas and Hybrid Teas which have been protected during the winter with Bracken or straw should now have the protecting material removed without further delay. If this is neglected, some of the lower buds advance prematurely, and so waste the energy of the Rose bushes. Any blanks which occur ought to be made good at once.

Sweet Peas.—Trenches which were thrown open early in the winter should now be filled in, so that the soil may be in a firm, settled condition before planting-time arrives. Too much farmyard manure ought not to be used, and all that is employed must be broken up and well mixed with the soil during the filling in of the trench. Bone-meal, soot, leaf-mould, lime, chopped turf and some reliable Sweet Pea manure should be included. See that all the ingredients are thoroughly incorporated one with another. This can only be brought about by repeated turnings of the mixture in the trench. The young plants at present in pots must be kept cool and well ventilated, so as to encourage a firm and sturdy growth.

Ivy Clipping and Laurel Pruning should be finished during the early part of March. Choose calm weather if at all possible for this work. Laurels are best pruned with a hand-knife and not clipped.

Violas.—The lights having been removed from the Viola frames for the past fortnight or more, a start should be made to clear the frames in readiness for occupation by other bedding plants. A border is most convenient for the Violas, which ought to be planted closely together in lines. If a quantity of leaf-soil and sand is added, the plants will root very freely, and so make good material for bedding out later on.

East Lothian Stocks are now ready for pricking out into cold frames. Being fairly hardy plants, they should not be coddled in any way. Stocks resent a free use of the watering-pot, so when pricked out an occasional spray with the syringe will be all that is needed if the frames are kept shut until the plants have recovered from the check.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

SOME GOOD LIGHT-COLOURED FOLIAGE PLANTS.

LOOKING round the alpine-house on a cold, damp winter day reminded one of the usefulness and beauty of many of the plants with light-coloured foliage. Enumerated below are a few of the most striking, beginning first with *Achillea Kellneri*, which has long, narrow serrated leaves. Its beauty of foliage is only rivalled by the pleasing white flowers borne on stems a few inches high over the greater part of the summer months. The *Milfoils* include many varieties indispensable to every rock garden, not only on account of their pretty foliage, but also for their profusion of bloom. A few of the most noteworthy are *A. argentea*, *A. Clavennæ*, *A. Grisebachii*, *A. Huteri*, *A. serbica* and *A. Wilzeckii*.

Anthemis Aizoon, from Northern Greece, has lanceolate leaves covered with down, and bears white Daisy-like flowers in the summer. *Anaphallis formosa*, sometimes called *Achillea Aucheri*, is quite distinct from the foregoing, its flat, delicately formed leaves being of a lavender grey tint and emitting a very pleasing scent; it reaches a height of about nine inches and has snowy white flowers.

Artemisia argentea.—This species grows to about eighteen inches high and has very freely divided leaves covered closely with minute silvery hairs, and bears pale yellow flowers in July. *A. pedemontana* has handsome silvery foliage, grows about six inches high and bears white flowers from June to August. *A. stelleriana* is taller and larger in all its parts than the foregoing. Though of a somewhat untidy habit, it is, nevertheless, a useful foliage plant. It has large lobed leaves of a striking silvery white colour, 2 inches in length, covered on both sides with down.

Corydalis Wilsonii is truly a plant that ought to be in every collection. Of noble and graceful habit, it is deserving of wider culture. The leaves are Fern-like, smooth and silvery. Towards the end of the summer the plant bears a graceful spike of rich golden yellow flowers. It is beloved of slugs, and needs protection here in winter from both slugs and weather.

C. tomentosa is a new and little-known variety, with foliage and habit slightly different from the preceding. The leaves are not quite so erect as those of *C. Wilsonii*, also both stem and leaves are covered with minute hairs. The spikes of pale yellow flowers are produced freely, and have set seed in generous fashion here in the early summer. It is better for protection in winter, either by placing a piece of glass over the crowns or by lifting and placing them in the alpine-house.

To further swell the quota we have *Helichrysum lithospermæfolium*, a neat, shrubby "everlasting" with long, narrow, pointed, white leaves. *H. frigidum*.—This little native of Corsica is a perfect gem of not more than an inch high; its minute, shining silvery leaves are surmounted in May and June by dazzling white flowers. This, without doubt, is one of the choicest of the family.

Origanum Dictamnus (Dittany of Crete) is an uncommon sub-shrubby species 1 foot high, its thick ovate leaves covered on both surfaces with heavy woolly down. A pleasing contrast to the foliage is the slightly drooping heads of pink

flowers in July and August. *Santolina minima elegans*, a little member of the Lavender Cottons, grows about nine inches high, and is of compact habit. It has small silvery grey leaves crowded on upright stems, and is very effective planted in large masses either in the rock garden or border. Lastly, *Teucrium aureum* (syn. *Polium*), a very beautiful prostrate grower with small, pointed, silvery leaves and golden flowers.

In addition to the modest praise given to the foregoing, one ought to mention an additional charm, viz., that of scent, which is possessed by most of those mentioned. For all some slight protection from the heavy rains in the winter months is a great benefit; for some, such as *Corydalis Wilsonii* and *Helichrysum frigidum*, it is here a necessity. Pieces of glass suspended by wires answer the purpose quite well, but the alpine-house has distinct advantages over this latter course. One of them is that of being able to admire some of the choicest of one's treasures in dry comfort when lingering in the rock garden is out of the question owing to the vicissitudes of the weather. To get the best results from the alpine-house, it is essential to give ample ventilation when the weather is at all fine. JOHN G. BROADHEAD.

Wooldale, Thongsbridge, Huddersfield.

TREES AND SHRUBS AS SCREENS.

A VERY frequent necessity in these days is the establishment of a screen of vegetation between the house and one or other of the numerous eyesores with which modern civilisation and an industrial age deface the earth.

Lucky are those whose lot is cast in the outer suburbs, for instance, if they have escaped the doleful experience of waking some morning to find a row of jerry-built cottages, a factory, or a smoke-stack showing its unwelcome beginnings, where previously a pleasant landscape spread before the eyes. The same problem, however, very frequently presents itself in quite rural districts; there is, perhaps, no subject connected with the planting of trees and shrubs on which expert advice is more often sought. The ideal tree for the purpose of blocking out unsightly objects would be one that is of close habit, evergreen and quick growing. But although there are plenty of evergreens that make perfect screens, such as *Holly*, *Holm Oak*, *Box* and *Yew*, they grow too slowly to meet the wants of many people. Life is short and the modern builder is quick, and the middle-aged man is not content, as a rule, to wait twenty, it may be thirty, years for such trees to grow high enough to fulfil their purpose. In such a case, if an evergreen vegetation be insisted on, reliance will have to be placed on the conifer family exclusively. So far as I know, there is no evergreen broad-leaved tree which, in our average climate, will compete in rate of growth with such things as *Douglas Fir*, common *Spruce*, *Corsican Pine* and its varieties, or *Picea excelsa*. In country places a plantation of these with *Scots Fir* added will make as quick growing and high a screen as anything. In hot, dry districts, however, neither *Douglas Fir* nor common *Spruce* is reliable; and *Pinus excelsa*, although it grows a yard a year in suitable places, is not suited everywhere. On the whole, the *Corsican Pine* is, perhaps, the most reliable and unfailing of big, quick-growing evergreens, especially on the outskirts of cities.

Where space is limited, especially as regards width, nothing, I believe, in the conifer family will prove better than the *Servian Spruce* (*Picea Omorica*) or *Lawson Cypress*. The first of these is proving remarkably well adapted for suburban cultivation; it grows quickly, is of dense growth, and it has a slender pyramidal habit which enables it to be planted closely, say, three rows deep, where a single row only of the conifers previously mentioned would have room to develop. In regard to close planting, the same may be said of the *Lawson Cypress*, although it does not grow quite so quickly. But when all is said, none of these quite meets the case near towns, where buildings are apt to spring up, so to speak, in a night. Unless the planter is content to wait (and then *Holm Oak* and *Holly* together, with the two conifers just mentioned, should be planted), recourse must be had to deciduous vegetation. And that I consider will be found nearly always the best, cheapest and quickest; for a deciduous belt, if wide enough and thickly planted enough, makes a very effectual screen in a few years.

In considering deciduous vegetation, one's thoughts immediately revert to the *Poplars*, and it is on them, indeed, that one must chiefly rely. The very mention of *Poplars*, however, will, no doubt, cause some interested in this matter to make a wry face. So I hasten to put myself right by saying I do not include those hybrid *Poplars* which abound to such an extent in the London district and go by such names as *Canadian*, *Black Italian* or *New Canadian Poplars*. "Lout" is perhaps an unseemly word to use in connection with any tree, but I know none that quite so well describes these *Poplars* in the young and half-grown state—their coarse, ungainly growth, their grossness of appetite. For the present purpose their one recommendation is rapidity of growth, which amounts to anything up to 6 feet a year. If a screen must at all costs be obtained in the least possible time, and the width of space for planting is not limited, then the *Black Italian* or *Canadian Poplar* (*Populus serotina*) will fulfil the purpose as adequately as anything. But there are other *Poplars* of better breeding and greater distinction than this that may well be used.

In selecting deciduous vegetation, regard must be had to density of branching as well as to quickness of growth. Many trees would serve our purpose when in leaf or, say, for seven months in the year, but fail when in the leafless state through the thinness of their branching. The *Black Italian Poplar* is one of them. For a narrow belt there is nothing that surpasses the ordinary *Lombardy Poplar*, either for density of branch in winter or quickness of growth. The tree itself is cheap and readily propagated by leafless or winter cuttings, and it may be planted in double or triple lines as near as 8 feet apart. In passing, it may be noted that a double row planted diagonally (or alternately) is always needed for the formation of a good screen, whatever the species used. *Bolle's White Poplar* (*P. alba pyramidalis*) is also a useful tree for a narrow belt, scarcely so fast growing as the *Lombardy*, but broader in proportion to its height and more pleasing to the eye in summer through showing swift flashes of the silvery under surface of the leaves in a breeze.

The comparatively new *Balsam Poplar* (*Populus trichocarpa*) from *Vancouver Island* and other parts of Western North America is likely to prove of great value in this connection. A very handsome tree, with foliage bright green above and bluish white beneath, diffusing a balsamic odour

in the spring, it is also of splendid vigour. I know a tree that in fifteen years was well over fifty feet high. Then there is that interesting form of Black Poplar with downy shoots (*Populus nigra* var. *betulifolia*), much denser as well as neater in habit than the Black Italian or *P. nigra* itself. There may also be mentioned the Berlin Poplar (*P. berolinensis* or *P. certinensis*), a tree of slender columnar growth, very popular in the outskirts of the Prussian capital. Although a hybrid, it exists in both sexes, the male being preferable and growing 3 feet to 4 feet yearly. The grey Poplar of the British Isles, a vigorous and handsome tree, is worthy of more notice than it gets, and there may be others, but sufficient has been said to show that the ousting of every other Poplar by the Black Italian is not justified.

From their nature, trees with small leaves make a better winter screen than do large-leaved trees, because their branching is closer. A Catalpa, for instance, or a Magnolia, a Walnut, Hickory or Ailantus are of little use for a winter screen, because their leafy canopy needs proportionately fewer supports. One of the best small-leaved trees is the Wheatley or Jersey Elm (*Ulmus sarniensis*), a tree of pyramidal growth, densely twiggy, and if not rampant like the Poplars, still, a quick grower. Its habit makes it suitable for close planting. The common Birch again has the same merit of density in winter, added to which its unsurpassed grace of habit and its silvery trunk should gain it a place in any screening belt of medium height.

In the foregoing notes the chief consideration in view has been to suggest the best trees for a high screen of vegetation—anything, say, from 35 feet to 60 feet high. If one of only half that height is needed, the object can be attained not only more quickly, but with much greater choice of material. Some of the first-class nurserymen can, as a matter of fact, supply deciduous material quite safe to plant up to 12 feet or 15 feet high. It is only necessary to mention a few to indicate sufficiently the class of tree to plant. In the *Prunus* tribe the fastest growing is *P. Mahaleb*, but the double-flowered Bird Cherry may also be recommended. Mountain Ash is useful, and, as uniting attractiveness with quick growth, the following may be noted: *Pyrus baccata* and *P. pinnatifida*, *Acer dasycarpum* and *A. platanoides*, *Æsculus carnea*. In places with a climate of moderate mildness, *Cupressus macrocarpa* and *Eucalyptus Gunnii* are useful evergreen trees, because of their rapid growth. Of a more shrubby type and adapted for outside or front places, the following list is offered: Deciduous—*Cotoneaster frigida* and *C. bacillaris*, *Genista virgata* and *G. cinerea*, *Philadelphus grandiflora* and other species (very useful in the dense interlacing mass of branches up to 12 feet high), *Berberis aristata*, *Cornus alba*; evergreen—*Cotoneaster buxifolia* (a splendid "block" up to 8 feet or 10 feet high), *Escallonia exoniensis*, *Ligustrum lucidum*, *Rhamnus alaternus*, *Elæagnus pungens*.

It sometimes happens that where big trees exist on the outskirts of the garden, their lower branches have disappeared, and thus leave open to the view beneath them mean buildings, outhouses, or other unsightly objects beyond. One of the most difficult problems in gardens is the filling up of vacant spaces beneath large trees, especially greedy-rooting ones and those whose canopy is so close as to make heavy shade during the summer. Few shrubs can withstand the lack of moisture and of light. Best of all, undoubtedly, is the *Aucuba*,

a plant whose capacity for thriving beneath such trees as Horse Chestnut and Lime is astonishing. The common Privet is good, but better is the oval-leaved one, because it retains its foliage longer. Of dwarf things the Butcher's Broom is about the best in very dense shade. When the shade is not so deep, as, for instance, under trees like Oak and Elm (it may sometimes be advisable to remove a lower branch or two to let in light), a greater variety may be got to grow, such as Holly, Box, Pontic Rhododendron and common Mahonia. But on the whole there is little choice. Such a position is about as evil a one as a shrub can be doomed to live under. If a presentable front of greenery on the garden side can be attained, the planter may well be satisfied.

W. J. B.

HARDY FERNS FOR SHADY PLACES.

IN a great many gardens there are numerous situations where, owing to the shade of adjoining buildings, walls, or overhanging trees, the majority of flowering plants refuse to thrive, and consequently these places are, more often than not, far from attractive for the greater part of the year. This ought not to be. In the many and varied families of hardy Ferns we may find beautiful and interesting plants that can, with a comparatively small amount of trouble, be induced to grow well in such places and give us their graceful fronds in abundance for many months of the year. Apart from their usefulness in transforming erstwhile ugly spots into dales of beauty, these hardy Ferns are well worth a place in the best gardens, because no other plants will provide us with such an atmosphere of refreshing coolness on a scorching hot day in midsummer. Nor must we forget their winter beauty. If the dead fronds are allowed to remain *in situ*, as they should be, until well into the spring, they provide quite a study in russets and varying shades of brown during the dull days of winter, when interesting features in the outdoor garden are none too plentiful.

Another feature that ought not to be overlooked when hardy Ferns are under consideration is their almost unique suitability for association with flowering plants that either appreciate fairly dense shade in summer or which flower early in the year, when the biting blasts of the slowly lengthening days sweep over the land, and when the shelter of the dead fronds is so welcome to their floral neighbours. One has vivid recollections of the companionship of a riotous mass of hardy Ferns and stately Foxgloves in a woodland glade, where shade and moisture, with an abundance of decaying vegetable matter in the soil, were evidently highly appreciated by the twain. But even more vivid is the recollection of a woodland scene in the cold, almost cheerless days of January and February, when Snowdrops, Scillas, Christmas Roses, hardy Cyclamen, the dainty little *Narcissus minimus* and its larger, though almost equally early, *confrère*, *pallidus præcox*, were nestling their flowers contentedly in the curled russet fronds of the Ferns. Such a scene is possible in every garden where tall trees, excepting Beeches and those of an evergreen character, are present. A splendid object-lesson in this style of growing hardy Ferns may be seen any day at Kew, at the foot of the mound whereon the storks make their nest and which is hard by the Cumberland Gate. There always

appears to me to be something akin to the best traits of Nature in this association of winter flowers and summer Ferns. The one provides protection for the others at the season when it is most needed, and both seem to derive some benefit from the association, though the flowering plants, I think, score the most points.

However we may decide to group or associate our hardy Ferns with other plants, a few points are essential for successful cultivation. It will have been gathered, from what has already been said, that the majority of hardy Ferns suitable for growing in our gardens like a cool situation and soil that is reasonably moist and contains a good proportion of decaying vegetable matter, generally in the form of dead leaves. This is not always easy to arrange, particularly where the plants are to be grown under the shade of trees; but even though the soil there is not so moist as we would like, many of the Shield Ferns or *Polystichums*, the Broad Buckler Fern (*Lastrea dilatata*) and the Lady and Male Ferns will thrive. But previous to planting, the soil should be well and deeply dug—as deeply as the roots of the trees will allow—and if poor, some good fibrous loam, old decayed leaves and some short, well-rotted manure thoroughly mixed with it. Hardy Ferns that are grown under trees in this way *must* have generous supplies of water during hot weather, but this is not, in most gardens, difficult to arrange, and the results will certainly more than compensate the owner for the outlay.

Where the shade is supplied by surrounding, not overhanging, trees, boulders of rock, buildings or walls, and where the soil is naturally moist, the many beautiful forms of the Hart's-tongue Fern will thrive to perfection. The variation among these is really wonderful, yet I must confess that few appeal to me more than the plain-fronded type. In too many the foliage seems distorted and far from what Nature intended this beautiful Fern to be. With its roots almost in water, that most noble of all hardy Ferns, the Royal Fern, *Osmunda regalis*, and its dwarfer variety *gracilis*, will make a stately feature in the shaded garden. One of the most pleasing features of a rock garden in summer is its moist corner bedecked with hardy Ferns, or the tumbling cascade, the sides of which are fringed with swaying, graceful green fronds of perhaps that gem of hardy plants, the Killarney Fern, the foliage of which must ever be covered with a film of moisture to preserve it from the least suspicion of a drying wind. The subject is one that could be pursued indefinitely, so numerous and varied are the Ferns which are hardy with us; but enough has been said to draw attention to their usefulness and attractiveness at all seasons.

W. F.

The Birmingham Flower Show, 1915.—The committee of the Birmingham Horticultural Society are an enterprising body of men who are not content with their exhibition merely at usual. They are issuing this year the most attractive schedule of prizes the society has yet issued, and in it is announced that as an appreciation of the society's progress the Council of the Royal Horticultural Society are sending a deputation to the Birmingham Flower Show, which is to be held on July 16 and 17, when the much-prized additional Royal Horticultural Society's awards will be made to meritorious exhibits. The secretary is Mr. William G. Carradine, 36, Hamstead Road, Birmingham.

THE GARDEN.

No. 2260.—VOL. LXXIX.

MARCH 13, 1915.

NOTES OF THE WEEK.

The Earliest Large-Flowered Daffodil.—On Friday of last week we were pleased to find some open flowers of *Narcissus pallidus præcox*, which is the earliest of all the large-flowered set to blossom outdoors. Its pale yellow flowers are very welcome as an earnest of other and bolder forms, and one can only regret that it does not increase more rapidly. In many gardens it actually deteriorates, but, even so, it is worth while expending something on a few fresh bulbs each autumn.

Maidenhair Fern Fronds from Queensland.—A movement is on foot for the importation of large quantities of dried fronds of *Adiantum formosum* from Queensland. This plant, we understand, is found in large quantities in the scrub of Northern and Southern Queensland. As Maidenhair Ferns can be so easily grown in quantity in this country, we do not think there is likely to be any great demand for dried fronds.

Trial of Spray-Nozzles at Wisley.—The attention of makers of, and dealers in, spraying machinery is drawn to the trial of spray-nozzles to be carried out at Wisley this year. Nozzles to be tried must be sent to Wisley by March 31. Entry forms, one of which must accompany each nozzle, may be obtained on application to the Director. Awards may be granted by the Council to meritorious nozzles, and a report of the trial will appear in the Journal of the society.

Alpines Under Glass.—One of the most interesting features at Kew just now is the little span-roofed house at the north end of the herbaceous ground. This is devoted to plants of lowly habit, many of them natives of mountainous regions, and under the shelter thus provided they are able to develop to the full the exquisite beauty of their blossoms. Mr. Irving, who is in charge, has this year been particularly successful with many choice plants, notable among them being the rose-coloured Saxifrage that was shown before the Royal Horticultural Society last week as *S. burseriana rosea*. As it is a hybrid, we believe that it will in future be named *S. Irvingii*. Saxifragas *Faldonside* and *Boydii* (yellow) and *S. bursiculata* (white), with the glorious white

varieties of *S. burseriana*, are other gems to be seen in this house just now.

Russian Kale: A Choice Vegetable.—On more than one occasion we have drawn attention to the value of Chou de Russie, or Russian Kale, at this season. Now that everyone is making an effort to grow more vegetables, we strongly recommend them, when making up the seed order, to include a packet of seed of this Kale. This need not be sown until the end of the month, or at any time during April, the plants being subsequently set out 18 inches asunder in rows 2 feet apart. It is a peer among Kales, and as it comes in for use now, before the

common Snowdrop are numerous, some of the best being *flore pleno*, the well-known double kind which grows so freely; *Imperati*, a strong-growing, early flowering form with erect leaves and larger flowers than the type; *octobrensis*, which only differs in flowering in the late autumn; *poculiformis*, remarkable in having both the outer and inner segments nearly equal in size; and *Sharlockii*, a curious form, the outer segments of which are tipped with green, while the spathe is very long and divided into two parts.

An Easily Made Rustic Support.—A few days ago, when visiting the garden of a friend, we were interested in a simple rustic support that he had

erected for Loganberries and similar fruits. This consisted of ordinary agricultural wooden hurdles, such as farmers use extensively. These are about five feet high, and to give them additional height they had been raised 1 foot from the ground and supported by stout wooden posts. The foot of space left at the bottom was no detriment, as the long rods of the fruits do not need supports at that point. A rustic fence or support such as this is easily made, and could be utilised for rambler Roses or any other strong-growing plants. If treated with creosote a few weeks before the canes were fastened to them, the hurdles would last for years.

A Message from French Horticulturists.—In reply to the resolution passed at the annual general meeting of the Royal Horticultural Society, and reported in a recent issue, the following has been received by the Council from the

Société Nationale d'Horticulture de France: "Your kind letter of February 5 has been read at the meeting of the Conseil d'Administration, and also at the last general meeting of members of the society. It was very encouraging to our horticulturists to know that our colleagues of Great Britain took such a keen interest in their misfortunes, and that they even proposed coming to their assistance when the time arose for re-establishing destroyed horticulture. Kindly ask your society to receive our most sincere thanks and accept same for yourself, for this expression of brotherhood, with whom we are happy to enjoy such amicable relationship."

A GROUP OF THE COMMON SNOWDROP (*GALANTHUS NIVALIS*) GROWING IN GRASS, WITH IVY IN THE BACKGROUND.

spring Cabbages, it should find a place in every garden.

Snowdrops in Grass.—Such flowers of the early spring are always attractive, whether grown in the rock garden or border, and especially in the grass. One of the best kinds for the latter purpose is our native plant, *Galanthus nivalis*, a group of which is shown in the accompanying illustration. Where the grass is too strong, they will not thrive so well; but under and in between trees, where the grass grows thinly, the bulbs increase rapidly, and soon form large tufts. When planting, the bulbs should be buried deeply, especially in light soil. The forms of the

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Home-Grown Vegetables and Our Food Supply.—I have read with very great interest the articles on "Home-grown Vegetables and Our Food Supply" which have appeared in your recent issues, and should like to take the opportunity of saying how thoroughly I endorse the excellent recommendations put forward. Specially to be commended is your suggestion as to how local horticultural societies could help. By members increasing their own vegetable cultivation, a good example is set to others who may have available ground, but who are somewhat uncertain as to what should be planted.

I have for some time endeavoured to point out to gardeners and farmers how they may do their country invaluable service, and, incidentally, earn additional profits for themselves, by sowing and planting such additional crops as will increase the country's stock of food during the summer and autumn, as well as during the next winter.

Such crops as I allude to will necessitate extra labour, but the general opinion now prevails that the economic conditions already existing in Germany must—apart from naval and military successes—bring the war to an earlier termination than was anticipated four or five months ago, and if that proves to be the case, there will be a vast number of men on the labour market for whom no regular employment can be procured immediately. I would urge, therefore, that the question of labour should not itself be considered a sufficient reason for neglecting to take such steps as are necessary to secure an ample supply of all such green crops as may prove invaluable for supplementing the food supply of the country. Those living in towns and the suburbs of great cities know to their cost that vegetables of all kinds have greatly risen in price, not perhaps due to any actual scarcity so much as to the inevitable rise in value which must follow when the main articles of food command a greatly higher price, for when such is the case all articles of food rise sympathetically.

We have, however, to remember that whatever ground there is for expecting an earlier termination of the war, there still remains the possibility of unforeseen contingencies leading to a continuation of the war throughout next autumn and winter, and in that event the price of "green crops" must rise far more than has yet been the case.

If prices continue to rise, or if they maintain their present value, there is still a good margin wherewith to pay an increased price for labour, and though labour is scarce, especially in rural districts, a high wage will command sufficient labour when that labour is most needed by the farmer. I consider, therefore, that in laying themselves out to help their country in her time of need, gardeners and farmers will have every prospect of very considerably increased profit accruing to themselves. Many have thought and hoped that the Government would offer some financial encouragement to farmers and market gardeners to extend their crops of vegetables suitable for general food, but I think the prospects of increased profits are in themselves so good that it is unnecessary to wait for Government aid. Such crops as I refer to are the following:

(1) Culinary Peas.—If long-strawed kinds are sown, little expense need be incurred in weeding

the crops, as the land is soon covered and the weeds have little chance of making headway. The picking is laborious, but it is done by piecework, chiefly by women and children, and if prices rule high, as seem inevitable, large returns are certain. But if the market is low, the crops may be left to ripen, and then there is the market open for Peas for boiling, &c.

(2) Dwarf French Beans.—Many thousands of acres of these are annually grown in France and other Continental countries, and large quantities might well be grown in our Southern Counties. Here, again, the picking can be done by women and children.

(3) Runner Beans.—Every allotment holder knows the value of Runner Beans, and in a year when food prices are high, a good return to the farmer or market gardener may be safely reckoned upon. Here, again, the women and children can easily do the picking for market.

(4) Broad Beans.—As the seeds of these Beans are eaten rather than the pods, they provide an invaluable farinaceous form of diet, and would be an excellent substitute (in part) for bread.

(5) Turnips, Swedes, Carrots, Onions, Leeks, Cabbage, Cauliflower, Brussels Sprouts, Vegetable Marrow and Parsnips have only to be mentioned to be recognised at once as extremely valuable substitutes for a portion, at least, of the meat diet which now forms the staple food of so large a proportion of our population.

(6) Potatoes.—Although in a normal season—and when meat and bread are not at war prices—the usual acreage of Potatoes planted in Great Britain may be nearly sufficient for our requirements, yet when it is possible the prices of meat and bread may continue to rise, or even to maintain their present high values, it is obvious that Potatoes may have to play a far more important part in the nation's food than is at present the case. It is, however, necessary to point out that within recent years Potato-growers have had to fight not only against the dreaded Potato disease, *Phytophthora infestans*, but the new and still more destructive wart disease, *Synchytrium endobioticum*, and the Board of Agriculture has rendered invaluable service by tabulating and issuing a list of those varieties which are absolutely immune to this new enemy of the Potato. [This list was published in our issue for Feb. 20, p. 93.—ED.]

I must apologise for the length of this letter, but the subject is one that cannot be dealt with in a few words only, and I have no hesitation in saying that it is one that demands the immediate attention of all who have it in their power to aid their country by taking very simple and easy steps to increase the nation's food supply.—ARTHUR W. SUTTON.

—Respecting the question of increasing our vegetable supply, the Royal Horticultural Society sent out a circular-letter some months ago advocating the same plan, which, I think, horticultural societies acted upon, more or less; and I might mention that this society received a letter some time ago from the Vegetable Products Committee asking for vegetables and fruit that could be spared for the use of the Navy. We are sending packages as often as we can for that purpose, but, owing to the great number of troops billeted in this neighbourhood, there is a large call upon our supply. This society is thoroughly in agreement with your suggestions for increasing our vegetable supply, which is now so much needed.—SAMUEL BROGDALE (Secretary), Saltwood Cottage Gardeners' Society, Saltwood, Hythe, Kent.

A Hint on the Cooking of Cabbage and Spinach.

Being no longer young, I have acquired a good many "wrinkles," and send this little one for cooking Cabbage and Spinach at this time of the year. Put the leaves of Cabbage, Kale, winter Spinach or Spinach Beet through the mincing-machine. It will retain the tough, fibrous midribs and let all the more tender and edible portion pass through. This, when cooked, can easily be rubbed through a sieve, and, with a little butter added, will make a tender and delicious dish of green vegetables.—ANNE AMATEUR.

Manure for Annual Flowers.—For some years past I have been convinced that most kinds of hardy and half-hardy annuals do better when the soil is not heavily manured. Owing to the ever-increasing difficulty in obtaining natural manures, a result of motor vehicles ousting to a large extent those drawn by horses, I, in common with many others, had to set about finding as good a substitute as possible. An enquiry addressed to the Editor several years ago elicited the information that Wakeley's Hop Manure had better be tried, as the spent Hops, in the process of decaying, gave to the soil the humus that forms such an essential part of natural manures. This manure I have tried for nearly all kinds of crops, and found it to answer admirably; but with annual flowers and Roses I have found it to give the best results. It seems to give just that amount of nourishment to the soil that annuals require, producing hard, sturdy stems that flower much more profusely than the more succulent ones that result from natural manures. I dig it into the soil during March, a week or two previous to sowing the seed, or, in the case of half hardy annuals, during May, a few days before planting. For Roses I fork it just under the surface when pruning is completed, and find that it imparts a fine colour to the flowers. I have no financial interest whatever in this manure, and my only object in writing is to bring it to the notice of others who, like myself, may be unable to obtain natural manures.—GEORGE OCKENDEN.

Undesirables for the Rock Garden.—The February 13 issue of THE GARDEN contains an article by "E. H. J." on undesirable plants for the rock garden. His list is useful and interesting, but the inclusion of *Cerastium tomentosum* as an undesirable plant calls, I think, for a little comment. I have several small bits of rockery here, and, to my mind, *Cerastium tomentosum* is not a plant to be despised in the garden. True, it will grow anywhere and everywhere—grow strongly, too—but I think he makes a mistake in saying it is undesirable. The way I grow it here is to plant it where it can have nice room and scramble down over some of the stones. Of course, it wishes to cover up a few neighbouring Saxifrages, but I find it quite easy to deal with. What I do is to cut it back rather severely twice a year, or perhaps oftener; cut it back to a safe distance from my plants. It looks untidy for a time, but not for very long. I do not think townsfolk (who often attempt a bit of rock garden), nor some of the country rock gardening folk who have no large gardening pockets, could do without this plant. Its silvery foliage and white flowers (which are given with such generosity), to my mind, form a pretty and, if the patch be large, a striking addition to the rock garden; and as I find I can keep my plants fairly easily within bounds, I should be the last to admit that *C. tomentosum* is an undesirable plant for the rock garden. I hope Mr. Jenkins does not mind my pointing this out.—E. T. E., Sheffield.

Under this heading, on page 77, "E. H. J." seems to have written somewhat too drastically regarding some things. I quite agree with him that all those plants with roots that ramify in all directions beneath the soil surface, and which in small pieces survive any treatment short of burning, producing fresh plants anywhere if accidentally distributed, are the veriest nuisances; but two things he mentions—*Sedum spurium* (I assume he includes all varieties) and the Vincas—are only abominations if allowed to become so, that is on account of neglect. They may be cut back and not allowed to overgrow other things. There are many rampant-growing plants that will soon, like them, become weeds unless kept by regular attention within the limits assigned to them, such as *Acænas*, *Tiarella cordifolia*, many *Sedums*, *Thymes* and *Veronicas*; yet in some rock gardens, where there are spaces beneath trees which have to be covered, some of these nuisances can be very well employed, though, of course, debarred from any positions where choicer plants will flourish. A list of all "root ramifiers" would be very useful to rock gardeners. In addition to those "E. H. J." mentions, there are *Achillea Ptarmica* and other varieties, *Hypericum calycinum*, *Linaria repens*, *L. r. alba*, *L. vulgaris* and others, and *Zauschneria californica*. These (rightly or wrongly) are commonly found in rock gardens, while the list might be extended to cover shrubs and border plants.—G. R. PHIPPS, *West Sussex*.

Beautiful Annual Flowers: The Malopes.—

The Malope belongs to the bold-growing class of annuals, and so should be grown in fairly large beds or borders to get a true idea of its worth. The illustration shown is of a 30 feet by 4 feet bed, in which the sowing was made in April. On lighter soils (ours is rather heavy) sowing might well be done in March. If the soil is given a good dressing of manure and well dug, little, if any, after assistance in the way of watering and feeding will be needed in normal years. Of course, in seasons like last year and 1911 several heavy waterings with clear water and manure-water would have to be given to maintain a good show of bloom. As the Malope is of a branching habit, besides being of an average 2 feet high, the seedling plants must be well thinned out; and to save later disappointment through sudden thunderstorms, place stout, twiggy sticks here and there between the plants when they are about a foot high. I only know of three colours among the Malopes—alba, blush, and a deep glossy rose colour. All are good, the latter particularly so, and perhaps this is the one called *grandiflora* by some growers. Some people confuse the Malope, the Malva and the Lavatera; but they are quite distinct as garden plants, though belonging to the same Natural Order of *Malvaceæ*.—C. TURNER, *Ken View Garden, Highgate*.

Shows, Schedules and Judging.—"Caledonia" touches upon an important point on page 99, issue February 27, when he chides judges for not withholding first prizes when exhibits are unworthy of such an award. In this direction, however, the Perpetual-Flowering Carnation Society invariably adopts a strong stand, for the simple reason that the appointed judges are all men who know the Carnation from A to Z, and therefore adopt a high standard. For this reason we invariably find that when competition is slack, a number of the leading awards are withheld, even in the special classes where traders actually offer the prizes. As might be expected, one or

two competitors grumble, but I have never known the judges to go back on their original decisions.—T. A. W.

Thanks are due to you for opening your columns to this interesting and, I hope, profitable discussion. I am in full agreement with "Exhibitor." I have seen glaring instances of incompetent judging at shows by men of "position" in the gardening world, instances which were a disgrace to the show. I also agree with him as to the lack of attention to trade exhibitors by show committees, and nothing could be better than the proposed Trades Show to teach them a lesson; for where would any of the "big" shows be without the trade? I agree with "Caledonia" to some extent, though, generally speaking, the prize money is none too liberal, and the exhibit is mostly worthy of the amount offered. As to schedules, these are mostly getting to be budgets of advertisements, which is unfair to both exhibitor and advertisers. Here, again, committees prey upon

judge." While this would undoubtedly be a most desirable innovation, the trouble is how to carry it out. Certainly at some of our large shows it is possible to have a dozen or so experts, who between them would be able to adjudicate the various classes satisfactorily; but how is this to be carried out in the case of the small provincial shows? During the last twenty years I have annually attended a number of local shows and, speaking generally, the positions I have taken part in awarding have given satisfaction. The most difficult people to satisfy are the Pansy growers. Very few professional gardeners nowadays cultivate the show and fancy Pansies, so that a large number of them know little about the points of these flowers. At many small country shows in Scotland the Pansy class is very strongly contested, and this is where trouble crops up for the average judge. Personally, I always endeavour to make a dead set against "overdressed" flowers, and then the keen Pansy man gets on the

A BORDER OF MALOPES. THESE ARE HANDSOME ANNUALS EASILY RAISED FROM SEED.

the nursery and seed trade, and exact amounts out of all proportion to the actual value of the media. For two or three pages of prize classes you find ten or twelve pages or more of advertisements, besides insets, making a bulky volume, and the many advertisements and small number of schedules actually issued renders the medium almost valueless. [Surely the trade are to blame for this.—ED.] Committees might profitably take a lesson from such schedules as York in this respect, and, above all, let them realise that more consideration must be given to exhibitors. Encourage exhibitors, especially the trade exhibitor, and the public will follow.—HAD SOME.

I am in full agreement with most of the views expressed by "Exhibitor," page 26, January 16 issue, but I fear his proposed remedy is scarcely practicable. He says: "It is essential, nay, it is but justice, that a judge should be selected who knows and has practical experience of the classes he has to

warp. Last year I got into trouble with one man for passing over his overdressed Roses. One thing for which the show committee ought to be responsible, but which is usually placed on the shoulders of the judges, is ascertaining that the correct number of blooms, fruits or vegetables, as the case may be, is in each exhibit. Take the case of Sweet Peas. Is it not absurd that a judge has to count the spikes or stems in perhaps a dozen or more exhibits in one class? (I have judged where several hundred vases of Sweet Peas were shown.) This is one reform that is certainly overdue.—C. BLAIR, *Preston Gardens, Linlithgow*.

FORTHCOMING EVENTS.

March 16.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1 p.m. to 6 p.m. Lecture at 3 p.m. by the Rev. Professor G. Henslow, M.A., V.M.H., on "The Passing of Darwinism." Royal Horticultural Hall, Westminster.

SOME ANNUAL FLOWERS FOR SPRING SOWING.

FORTUNATELY, the merits of many of our best annual flowers are now much more fully recognised than they were a decade ago. In a number of the best gardens of to-day, borders or beds are entirely devoted to these flowers, and the charm of the garden as a whole is considerably enriched thereby. The wide range of colour and form that we find in annual

and need fairly dry soil and a sunny position. Seed of a new race of hybrids of this plant, embracing a number of beautiful art colour shades, is also now obtainable.

Among annual Asters, a new variety that I grew last year, and which was generally admired, was named Sada Yakko. It belongs to the beautiful Comet section and has large, graceful flowers of an exceptionally pleasing shade of delicate pink. Among the annual Japanese Pinks, flowers that are not known nearly so much as they deserve to be, Rosalind and Harlequin gave a good account of themselves during the scorching

lings subsequently pricked out and hardened off for planting out about the second or third week in April. Quite a number of beautiful varieties have been introduced during recent years, a few of the best being Sunset, a dwarf plant with orange scarlet flowers; Crimson King; Moonlight, apricot yellow with red flush; Cottage Maid, white and pale rose; Gold Crest, rose pink tinged salmon and orange; and Golden Chamois, soft pink and gold.

A new Stock that I grew last year in quantity, and one which gave us hosts of flowers during the scorching days, was Webb's Crystal White. This was sown in early March in a cold frame, and the young plants put out the first week in May. Quite 95 per cent. of the plants gave double flowers. It is a dwarf-growing variety, specially suitable for bedding, the plants branching into as many as ten or twelve compact shoots, each of which is surmounted by a spike of white flowers which last well.

D. D.

PRIMULA CAPITATA.

WHILE quite one of the most distinct and desirable of the hardy species of the genus, this handsome Himalayan kind is not one of the most tractable from the gardening point of view. In other words,

it is not reliably perennial or calculated, even if so inclined, in some instances to do itself a full measure of justice. Another peculiarity—a drawback, too, if it be not rightly appreciated and catered for accordingly—is in the fact that it is, unlike the majority of its tribe, an autumn-flowering species. Hence from two points of view it requires to be well understood by the gardener. There are other species of the genus not reliably perennial, and which acquit themselves much better when treated on the biennial plan; but these are spring or early summer flowering, and may all come under the general recommendation to "raise them periodically from seeds." The subject of the present note, in being autumn flowering, differs, and its treatment should be on a more rule-of-thumb method.

It is usually recommended to sow *Primula* seed almost as soon as it is ripe, and if this be adhered to with *P. capitata*, and the seedlings grown on quickly, all will be well, and a good late summer flowering ensured. To sow in "spring"—an elastic term, by the way—would be quite wrong in many instances, inasmuch as the plants would be endeavouring to flower at the time of the autumn frosts. Like other Himalayan Primroses, this is of a bog or moisture loving nature, and only reaches its fullest development under such conditions or with those near equivalents—rich soils and shade. Like other vigorous-growing sorts, it is somewhat partial to cow-manure, and given this, with light loamy soils and shade, it appears as happy as in moister ground in fuller sun. The plant attains to 15 inches or so high, the deep Tyrian purple flowers in roundish heads in marked contrast to the silvery white meal with which both stems and calyces are endowed. The species comes freely and quite true from seeds, and is admirably suited to grouping, as the accompanying illustration demonstrates so well. Seed is best sown in early autumn, say, during August, as by so doing sturdy young plants are obtained before winter sets in.

E. H. JENKINS

A COLONY OF PRIMULA CAPITATA IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY.

flowers, together with the usefulness of many for cutting when well grown, demand that they shall be given their due, while their cultivation is so simple, and seeds are so inexpensive, that there is really no good excuse for omitting them from even the smallest garden.

Unfortunately, the very simplicity of their cultivation is a stumbling-block to many. We have been so accustomed to the voracious characteristics of our perennial plants that it is difficult always to remember that annuals do not need the same amount of stimulating food. Indeed, to get the best results from most kinds, soil that errs rather on the poor side is essential.

Undoubtedly the best and most useful of the new annuals is the Namaqualand Daisy, *Dimorphotheca aurantiaca*. The hot weather of last year suited this to perfection, and plants that were raised from seed sown in a cold frame in March commenced to bloom in May and continued to do so until the end of September, a feat that no other annual that came under my immediate notice accomplished. The flowers are of the best Marguerite shape, rich orange in colour, with a shiny black ring round the central disc. The plants grow about nine inches high, branch reely,

days of last summer. The seeds were sown in shallow boxes of sandy soil in a cold frame early in March, the seedlings subsequently pricked off, and finally planted out in ordinary loamy soil the second week in May. Both varieties have a good branching habit and double flowers, those of Rosalind being soft pink as they open, changing to a sort of rose colour with age, while Harlequin has white flowers streaked deep crimson.

Annual Larkspurs of the ordinary blue colour are favourites with most flower-lovers, but the various shades of red are as yet but little grown. These are listed by different seedsmen under diverse names, such as rosy scarlet, superb rose and carmine rose. All that I have seen are good, and there is really but little difference in their colours. Some strains are, perhaps, a little better than others. They need precisely the same treatment as that accorded the old blue Larkspurs, *i.e.*, sow them early in April where they are to flower, and thin them freely at an early stage of their growth.

Snapdragons, or *Antirrhinums*, although not strictly annuals, are more often than not treated as such, the seeds being sown during February or early March in warm frames or greenhouses, and the seed-

DAFFODIL NOTES.

Dimensions of Flowers.—I believe the custom of measuring flowers originated with the late Mr. Robert Sydenham and myself. At all events, once upon a time I never used to see anyone else at the game. Now it is becoming more common, as it has been found to be a useful addition to the description of a flower, and to be much appreciated by those who are not able to see the blooms themselves. I am afraid I have not thought much about how or on what plan these measurements were made until recently, when, on consulting "All About Daffodils," by Robert Sydenham, as to the size of certain varieties, I became aware that the several dimensions are given in a different order there from what they are in the "Daffodil Year Book."

Whether every tailor in every shop measures his customers in the self-same order I know not, but it is obvious that in the same shop everyone must do so, or otherwise the cutter-out would have a very perplexing time. Just so with regard to Daffodils; all who measure should do so in the same order. What that should be is relatively of little importance. The essential point is that everyone should adopt the same practice. I am going to ask the Royal Horticultural Society's Narcissus committee to adopt an official one, which, if it did, would, I feel sure, be very generally followed. I will refer to this again as soon as I know what has been done.

Technical Terms Used in Descriptions.—As a "bird of a feather" with measurements, the accurate use of such terms as "hooded," "starry," "imbricated," "claw-shaped," &c., seems an appropriate subject to introduce here. I am quite sure all do not mean the same thing when they use these words. The fact is that as the Daffodil is a parvenu as a "show" flower, sufficient time has not yet elapsed for a generally recognised vocabulary to have been evolved, as has been done in the case of the Tulip and Carnation. Time will remedy this, we may be told, or some might say that if only we would become botanists and adopt their universal language, much of the uncertainty would disappear. But we are not botanists and time is slow. The "line upon line" pace needs accelerating, and as a florist's and a garden flower the Daffodil seems important enough to-day to have a language of its own. A good many years ago I had some correspondence with the late Rev. G. P. Haydon on this subject, in the course of which he referred to the "necessity of plainer language in the description" of Daffodils. The following suggestions are partly his and partly mine. I hope in my notes of this season to get into the way of using them and any others that commend themselves, and which I will explain as they crop up. I have quite an open mind about most of them, so if readers can suggest better terms or will point out any impropriety in the usage of any technical term, I am quite ready to amend my ways. It would be most helpful to have standard words for our descriptions, and so avoid the same variety being described by R. H. Bath

of Wisbech in one way, by Cartwright and Goodwin in another, and by Bourne in a third.

Of the Flower.—"Drooping."—A drooping flower is one like William Goldring, where the face of the bloom points to the ground.

"Hooded."—When the perianth forms a less angle than a right angle with the corona tube, a flower may be said to be hooded. Example: Lucifer.

"Claw-shaped" or "elliptical."—When the segments curve in a greater or lesser degree towards the corona and form part of a circle or ellipse, the flower may be said to be claw-shaped or elliptical. Examples: Peter Barr, Golden Spur and Gem.

"Rectangular."—When the segments stand out at right angles to the corona or tube, a flower may be said to be rectangular. Examples: Tenby Daffodil and Easter.

"Imbricated."—When the divisions of the perianth overlap each other, a flower may be said to be imbricated. Examples: Whitewell, Victoria, Empire and Tenby Daffodil.

"Loose" or "loosely built."—When the segments of the perianth do not overlap or only a very little at their extreme base, a flower may be called loose or loosely built. Examples:

round. Examples: Easter, Empire, Circlet and Ring Dove.

"Rough."—When the segments are not all in the same plane or ellipse, but stand at various angles, or when the surfaces are ribbed and uneven, a flower may be called rough. Examples: Olympia, Torch and Mme. Plomp.

"Smooth."—When the surfaces of the segments are all smooth and in one plane or ellipse, a flower may be said to be smooth. Examples: Challenger, Steadfast and Michael.

"Reflexed."—When the perianth bends back towards the corona, e.g., cyclamineus, Queen of Spain, Dawn and Seville (slightly).

"Twisted."—When the segments of the perianth are curled or twisted between their base and apex, a flower may be said to be twisted. Examples: Princeps, maximus and Frank Miles.

Of the Corona.—"Trumpet-shaped."—When the corona is longer than, or quite as long as, the segments, it may be called a trumpet.

"Cup-shaped."—When the corona is shorter than the perianth segments, it may be called a cup.

"Eye-shaped."—When the corona is very much flattened out, or when, as in ornatus, it hardly stands up at all, it may be called an eye.

A BEAUTIFUL AUTUMN BED COMPOSED OF PALE BLUE AGERATUM AND PINK SINGLE ASTERS.
(See page 126.)

Frank Miles, Countess of Southesk and Santa Maria.

"Starry."—When the perianth segments are pointed and, being free from one another for a considerable portion of their length, stand out more or less at right angles to the corona, the flower may be called starry. Examples: Blackwell and Glory of Leiden.

"Round."—This is the opposite to starry. When the segments overlap from base almost to apex, so that their outer extremities or edges practically form a circle, and when those extremities are themselves rounded, a flower may be termed

"Expanded."—When the top is decidedly wider than the bottom, e.g., Sir Watkin, Bulbocodium, conspicuus and Diana.

"Straight."—When the top of the corona is practically the same width as the bottom, e.g., Queen of Spain, Nelsonii major and Mrs. Robert Sydenham.

"Spreading."—A very pronounced form of expanded, e.g., Whitewell, St. Olaf and Seville.

"Flanged."—When the top of the trumpet bends back, it may be said to be flanged, e.g., most trumpets. Queen of Spain is flanged; King of Spain is not.

"Fluted."—When the sides of the corona appear ribbed, it may be called fluted, *e.g.*, Bernardino and White Lady.

With these and similar words of definition may be joined qualifying adjectives, such as slightly, broadly, very, much, &c.

Conclusion.—"To everything there is a season, and a time for every purpose under the sun." Hence at the beginning of another season there seems an appropriateness in introducing the questions of measurements and technical nomenclature. If only there could be anything like an agreement come to among those who write of the Daffodil in papers and books, and those who compile lists from which the public are invited to buy, it would be a step in the direction of an ideal which would draw all of us into its net—perhaps even "Somerset," although I fancy the smart salesman will always do what he can to make the best of what he has to dispose of. If, on the other hand, a purchaser will take the trouble to keep in his noddle these two little proverbial bits of advice, "Look before you leap" and "Once bitten, twice shy," it will only be himself that he has to blame if he has reluctantly to place any of his purchases in the category which "Somerset," on page 99, described in Hebrew fashion by consonants only. JOSEPH JACOB.

P.S. — My apologies to my readers who want notes on individual varieties. These will begin next week.

A CHARMING AUTUMN BED.

THE illustration on page 125 represents an irregular-shaped flower-bed in the kitchen garden at Westwick, near Norwich, Norfolk, the residence of Colonel Petre. The photograph was taken quite late in September, when the effect was exceedingly pretty. To the left of the picture, and at the back of the bed, pale blue *Ageratum* was massed, so as to form quite a haze of pale lavender blue; while in front, near the pathway, single *Asters* of soft pink shades created quite a good colour picture and, incidentally, provided plenty of flowers for cutting. The bed on the other side of the pathway, and a portion of which is seen on the right of the illustration, was filled with some of the newer pink shades of *Antirrhinums*, and so was perfectly in keeping with the *Asters* and *Ageratum*. As all these plants can be easily raised from seeds sown at the present time, this note and illustration may, perhaps, suggest some simple colour combinations to other readers. It would, I think, be interesting if other readers would send notes and photographs of good colour effects, as these would prove a useful guide to amateurs when planning their gardens,

T. S. H.

THE CULTIVATION OF ANNUAL STOCKS.

IT would be difficult indeed to find any annual flower that is more highly appreciated than the sweet-smelling Stock. Its appearance always brings vividly to mind an old-world garden that existed in one's childhood days, when spare pennies were expended on packets of seed from the local seedsman, the chief merits of which were the brilliant coloured illustrations that nearly covered the front of each. Ten-week Stock always had to be included, and the instructions on the back of

ADMIRATION STOCKS GROWING IN A BORDER BENEATH A DINING-ROOM WINDOW. SEED MAY BE SOWN DURING MARCH.

the packet told us that the seed must be sown thinly in pans or boxes of friable soil, placed in a warm frame or greenhouse, and the seedlings subsequently pricked off into other boxes or pans of light soil.

Alas! these instructions were seldom followed. "Friable" was not included in childhood's vocabulary, and "pans" called up visions of an irate cook who threatened our invasion of her domain with a deftly wielded kitchen utensil of that name. But still, a few fragrant Stocks, although mostly singles, were reared, with the aid of a broken pane of glass laid over a fairly deep box.

In more recent years annual Stocks have undergone considerable change, and one must admit that it has been a change for the better. In place of, or rather in addition to, the stiff, short-lived Ten-week varieties, we now have the set that seedsmen list as Intermediate, a race of plants that, it is true, commence to flower a little later, but make up for this by continuing the display well into November. And they are much more graceful than the annual Stock of our childhood. Bold plants they are, attaining a height of nearly eighteen inches, and branching so freely that one needs to plant them quite a foot apart.

Those shown in the illustration are a strain that Messrs. E. Webb and Sons send out as Admiration Stocks, a fitting name for some very beautiful flowers. In separate colours, such as almond blossom, white, rosy lilac, flesh colour and violet, these Stocks can be had, but personally I prefer them all mixed. Shocking bad taste, no doubt; but, after all, what is the use of having a garden of one's own if one's likes and dislikes cannot be pandered to! I think the craze for separate colours is being much overdone, and where the flowers are of quiet hues, such as those enumerated above, a mixture of them all gives me, and, incidentally, most of my gardening friends, far more pleasure than a mass of, say, white or violet. But everyone to his own taste.

The plants illustrated were raised from seed sown in boxes of sandy soil towards the end of March last year, and placed in a cold frame that was well ventilated on all favourable occasions as soon as the seedlings were above the soil. When about an inch high, these were transplanted 3 inches apart into other boxes, and planted out in the border the first week in June. Quite simple, and a good use to which to put the cold frame.

Respecting the soil in which to grow and flower these Stocks, I find that they are not at all particular, so long as it is well and deeply dug and contains a fair amount of well-decayed manure. This latter is essential, not perhaps so much for the nourishment it

yields as for the coolness that it imparts to the soil during very hot weather. As to situation, anywhere that is open will do, though I must confess that I like to have them round the dwelling-house, so that their delicious, old-world fragrance can be inhaled through open windows and doors. The little border illustrated is situated immediately beneath the dining-room window. If additional fragrance is needed around the house, and it is almost impossible to have too much, sow Mignonette, Night-scented Stock, and p'ant Sweet-scented Tobacco. The last two are so good during the evening, when their flowers open.

C. O.

HARDY ANNUALS AMONG SHRUBS.

AMONG the varied positions in which hardy annuals may be effectively planted, the accompanying illustration of Godetias depicts a valuable instance. When planting a new shrubbery border, or remodelling an old one, the operator may choose to do one of two things. Many cultivators plant the trees and shrubs fairly close together to secure an immediate effect, cutting out or transplanting a few from time to time as they become crowded. To this method we have the alternative illustrated, namely, planting the shrubs or trees which are to remain permanently, and growing hardy annuals for a few years among them till they are large enough to occupy practically the whole of the ground.

It will at once be seen that by this method the permanent shrubs are able to grow and develop their full beauty unhampered by others close by. Another consideration is that from July to September, when the annuals are flowering freely, the season for blooming of most trees and shrubs is past. Besides providing plenty of colour in the pleasure grounds, most of the hardy annuals, when used in quantity, will supply armfuls of flowers to cut for indoor decoration.

Soil Preparation.—Having prepared the ground well for the shrubs, beyond raking the surface soil fairly fine and level previous to sowing, little or no preparation will be necessary the first year. In succeeding years, or in alternate years, it is worth while digging in decayed farmyard manure some time during the winter, or in the autumn, previous to sowing. This will benefit both the shrubs and annuals. Whether the seeds of the annuals are sown in the autumn or the spring is a matter of convenience and opinion. When ample space permits, both methods may be practised; but if only one is chosen, sow in spring when the weather is favourable about the end of March or early in April. Plants from this sowing naturally flower later in the season than those sown in the autumn, at a time when there are fewer trees and shrubs in blossom. With this method of growing annuals it is usual to sow where the plants are to flower, the work of transplanting in such large quantities being out of the question. Thinning is very necessary, though one need not be quite so thorough here as in the herbaceous borders. Always leave ample space round the shrubs to prevent the annuals interfering with their growth.

The Best Kinds.—A selection of the best hardy annuals to grow in this way should include Godetia Double Rose (illustrated), producing long sprays of rose pink flowers on plants 2 feet to 3 feet high; Double Crimson, and Lady Albemarle (white). *Clarkia elegans* Firefly (rosy crimson), Double Salmon Scarlet, Snowball (white) and Double Salmon; all these sorts grow 2 feet to 30 inches high, producing a profusion of double

flowers. Most annual Poppies are suitable for the purpose in view, the best being the Shirley Poppy, *Papaver commutatum* (umbrosum), the scarlet and black Poppy and the Double Opium Poppy. The single Chinese Aster, *Callistephus sinensis*, when grown in quantity, is a lovely sight during September and October. Growing about eighteen inches high, the plants produce quantities of flowers in numerous shades of mauve, blue and pink, as well as pure white. One of the richest effects with annuals is produced by an extensive planting of the double Pot Marigold, *Calendula officinalis* Orange King. The plants grow a foot high, thrive in comparatively poor or rather dry soil, and last in flower for a lengthy period. To this Lemon Queen, a lemon yellow variety, provides a pleasing contrast. In mixture or distinct colours the annual Candytufts deserve attention. *Salvia Horminum*, the Blue Beard Salvia, is very showy with rich purple bracts, and grows 18 inches high. The Sweet Alyssum, Mignonette, Larkspurs,

I do not feel that the trial was satisfactory, and shall endeavour to give them a fairer trial this year. The pieces taken off were the first or main growths, which were removed when the basal buds began to develop. A better plan would be to take some of the basal growths when sufficiently long, as the older growths do not seem to get away well.

The cuttings were rooted in a box of sandy soil stood on the open staging of a cool greenhouse. After rooting, the top buds broke out first. Whether this would be the case if younger growths were selected as cuttings I have yet to learn. I do not feel very confident that plants from cuttings would rival, or even equal, those procured from seeds, but the subject is one well worthy of trial, and if others will grow a few plants from cuttings—without, of course, depending on them—we might find out what advantage, if any, there is from this method of propagation.

Another trial which I made last year, but which,

DOUBLE ROSE GODETIAS GROWING BETWEEN YOUNG SHRUBS.

Collinsia bicolor, *Eschscholtzias* and *Cornflowers* are also adapted for the purpose in view.

In the illustration it will be noticed that some of the plants have single flowers. This is due to the fact that seeds have been saved for several years from the plants, no effort having been made to secure only double flowers. It is worth recording that there are sufficient self-sown seedlings at the present time in the position illustrated to provide a display of Godetias this year. A. O.

SWEET PEAS FROM CUTTINGS AND AS STANDARDS.

HAVING heard that Sweet Peas may be easily propagated from cuttings, I made the trial last year, and although I was successful in rooting the pieces put in, they did not become good flowering plants. As, however, Sweet Peas did not do well with me last year except with autumn-sown plants, which flowered well for a brief period.

on account of the bad season, was only partly successful, was to grow the Sweet Pea as a standard plant. I see no reason why any plant which is of a tall-growing habit and makes free growth should not be capable of being (shall I say?) standardised. I have it in my mind in a modest way to emulate the beauty of a weeping Rose by the use of the Sweet Pea. I selected some strong-growing plants of *Hercules* and forwarded them in 6-inch pots in the greenhouse, picking out all the side growths until they were 4 feet high, when they were planted out. They certainly made a head, but not sufficiently to train them loosely over a framework, as I had intended. Here, also, I shall endeavour to try again, and I invite other readers to do likewise. But instead of confining myself to one plant, I shall grow two and train the growths up together, as I have successfully done with *Heliotropes*. A clear stem of 4 feet to 5 feet will be as high as I shall take the plants until I am assured of the success of the venture.

WILLIAM F. ROWLES.

SOME HINTS ON POTATOES.

THE Potato crop is one of the most important, whether grown in garden, allotment or field. Many cultivators simply dig up the soil, which has been left undug all the winter, and then put in the sets without any manure or other preparation. Others go to the opposite extreme, trenching in the autumn, forking up the soil in the spring or late winter, applying manure in the autumn and again at planting-time, thus making the soil too rich. The aim should be to obtain a strong, healthy haulm, but not too luxuriant.

The Treatment of the Tubers.—Many cultivators select the seed tubers from the general store, and very often they possess sprouts 6 inches long. This means a loss of strength. Tubers so much weakened cannot produce crops equal to those boxed early and possessing one or two short, sturdy sprouts—the first that has grown from the tuber. Much can be done to improve the sets during the few weeks prior to planting. It is not necessary to box them all if this is inconvenient, but all the early kidney varieties should be placed on end in single layers in a cool, dry, light shed or store. The maincrop tubers will benefit if spread out thinly in a similar place; but if several tubers in depth, they must be gently turned over once every week. Many bushels can be thus dealt with in a short time. I remember being shown over the seed stores of the late Mr. James Clark, the raiser of the well-known Magnum Bonum Potato, and it was an object-lesson of great value. He gave keen attention to the smallest details, and cool storage in thin layers was one; abundance of air and light another. He obtained wonderfully good crops as a result, but never owing to excessive manuring. While chatting with him, he remarked that yellow-fleshed Potatoes were generally the best flavoured, but owing to their colour many persons objected to having them on their tables. If we can get heavy crops of sound, yellow-fleshed tubers, I think it would be folly to object to the colour.

Planting and Interplanting.—Many maincrop varieties could with advantage be planted earlier than they often are, and in light soils a little deeper, too. Cultivators who possess small gardens, and others who have fairly large ones, make a practice of planting Cabbages or other plants of the Brassica family between the rows of Potatoes, thinking to make use of the ground to the very best advantage; but do they? I think not. Judging from experience, I have noticed that the Potatoes have suffered considerably. Cabbages, &c., absorb much moisture and nutriment from the soil in a short time, and the loss in the Potato crop is not compensated for by those plants. The wisest course is to allow the Potatoes to have possession till they are harvested. Following the early varieties, Cauliflowers, Savoys and winter greens may be the rule. After late Potatoes a crop of Turnips may be secured, and the general result will be more satisfactory.

Newly Broken Ground.—Probably owing to the lead given by the Editor in his admirable article, hundreds of cultivators will break up grass land and land that has been untilled practically for a number of years. Now, in such cases no other crop can surpass that of Potatoes as a first-crop. Cabbages, &c., would not make such progress as Potatoes would. Furthermore, the cultivator, in paying the necessary attention to the Potatoes, will be enabled to thoroughly clean, it may be, much land that is now in a bad state and infested with weeds. SHAMROCK.

A GOOD NEW MAINCROP POTATO.

The accompanying illustration represents a crop of what I consider to be one of the best maincrop Potatoes of recent introduction. It was sent out a year or two ago by Messrs. E. Webb and Sons

A GOOD CROP OF POTATO PROSPERITY, A NEW MAINCROP VARIETY OF GREAT PROMISE.

of Wordsley, Stourbridge, and named Prosperity. It is a robust variety, and with me very free from disease, the tubers leaving the soil in a beautiful, clean condition. These are almost round, with partly netted skins. The flesh is very solid, and consequently the tubers weigh well. The crop illustrated consisted of just over two and a-half bushels, and was the result of planting 14lb. of seed tubers. No doubt the crop would have been considerably more, but owing to the fact that I did not know it made such robust haulm, the sets were planted too closely together. It is a Potato that ought to have at least 3 feet between the rows and 18 inches between the plants in the row. The tubers have kept well, and now, early in March, cook nice and floury and keep an excellent colour, H.

NOTES ON VEGETABLES FROM SEED.

THE month of March is probably the most important of all periods to the kitchen gardener who relies on the bulk of his crops from seed. With the prospect of dear food, it behoves all to obtain the heaviest crops of vegetables possible, aiming rather at quantity than quality. My advice, then, is to generally arrange the rows closer, but not to sow the seed thicker in the rows, as nothing but harm results from the latter practice, which is all too common. So many persons seem to forget that the haulm of Peas, the leaves of Turnips and the tops of Carrots require room for development and maturity, which, under certain wrong methods of culture, they do not obtain, and thus we see so many moderate results.

Onions, usually sown in rows 14 inches apart, will succeed if sown an inch or two nearer. It is important that the surface soil should be fairly dry at sowing-time, or it is liable to knead and afterwards crack on the surface. In heavy soil Onions succeed admirably with a thorough preparation—deep digging or trenching in the autumn. Previous to sowing, give the surface a thick covering of wood-ashes, soot, old potting soil and roadside refuse. This, if lightly forked in not more than 6 inches deep, will form a capital rooting medium and greatly help to ward off mildew attacks, which, in a wet season, are occasionally troublesome. The large-growing types of Onion, like Ailsa Craig, are not so desirable for sowing in the open. What is most required is a variety that will give a heavy crop without much thinning, the bulbs of which will keep until Onions are ready the following year—varieties like Ar, Brown Globe, Bedfordshire Champion, James' Long Keeping, Southampton Champion and Nuneham Park. If a pickling variety is required, Small Paris Silver Skin or Improved Queen should be selected, sowing the seeds in rows 10 inches apart, not thinning the plants at all.

Carrots for the main crop should be sown at the end of March, or even a week later if the soil is not then in a suitable condition. Large-growing varieties, like New Red Intermediate or Long Red Surrey, make more foliage than some others, and should, therefore, be sown in drills 14 inches apart; Favourite, Scarlet Intermediate and Prizewinner, in drills 1 foot apart. Nantes, Early Gem, Model, Market Favourite and New Wonderful, all desirable, short-growing types, will succeed in drills 10 inches apart. Previous to sowing, and also at the time, a free use of wood-ashes and soot may prove most beneficial later on in warding off attacks of grubs, which in some soils play havoc with the Carrot crop.

Parsnips should be sown without delay in drills 14 inches apart. Hollow Crown, Student, Tender and True, and Elcombe's Improved are all desirable.

Peas may be sown now, choosing principally second-early and maincrop varieties. Of all vegetables, none is more hindered in cultivation by thick sowing of the seed than Peas. Too often double the quantity is used that is really necessary.

If the Peas were arranged 3 inches apart in the rows, instead of sowing nine seeds in the same space, the result would be different. The haulm would thicken naturally and the leaves would develop properly, giving longer and better-filled pods of finer Peas, possessing much more flavour. Not only do Peas require more space in the rows, but they need a corresponding amount between the rows. Instead of sowing the rows within 4 feet of each other, it is much better to allow double the space and, between, grow Potatoes, Turnips, Broad Beans, Cauliflowers, Spinach and other crops; and always, where possible, arrange the rows to run north and south, so that both sides of the row obtain an equal amount of sunlight. Among some hundreds of sorts it is difficult to satisfy all in making a selection. No one can err in sowing the following: Edwin Beckett (4 feet), perhaps the finest-flavoured Pea in cultivation; Duke of Albany (5 feet), too well known to need description—this Pea has probably held its high reputation longer than any other variety; and The Pilot (3 feet), quite one of the best of second earlies. Giant Delicatessé (4 feet) is another that deserves attention, being a heavy cropper of large Peas; Harvestman (5 feet) belongs to the same section. Maincrop varieties to sow now are Peerless (3 feet), robust in habit, heavy cropper of large Peas; Maincrop (3 feet), robust haulm, bearing an abundance of huge pods of large Peas; Quite Content (6 feet) is perhaps the largest-podded Pea in cultivation; Stourbridge Marrow (5 feet) produces huge pods, well filled with extra large Peas; and Veitch's Perfection (3 feet), which still ranks high for fine flavour.

Broccoli, Cauliflowers, Savoys, Kale and Brussels Sprouts should be sown at the end of the month in drills an inch or so deep which have been previously watered should the weather be dry at the time of sowing, which ensures quick germination much better than watering after sowing. The sowing of such seeds in drills 1 foot apart is better than in beds, as the soil between the drills can be frequently stirred, which aids growth very much, especially if fly is troublesome when the plants appear through the surface. Among many varieties the following will be suitable for general use—Broccoli: Michaelmas White, Walcheren, Winter Mammoth, Christmas White, Leamington, Knight's Protecting, Late Queen and Model, with the purple and white sprouting forms which are useful late in spring. Brussels Sprouts: Matchless for the main crop, and Scrymger's Giant for those who prefer quite small button-like Sprouts for their high flavour. Of Borecole or Kale, Ar and Favourite with Cottagers' Kale are reliable sorts. Of Savoys, Early Ulm and Drumhead are desirable for late use. Early Savoys in, say, October are really not much in demand. Cauliflowers Magnum Bonum, Early Giant and Veitch's Autumn Giant are sufficient for all ordinary purposes. Early

autumn Cabbages or Coleworts sometimes come in useful in September. Sow a pinch of seed in gentle heat about the middle of the month, prick out the seedlings in boxes, harden off, and plant in rows 15 inches apart. The Rosette Colewort is a useful sort.

Celery.—Aldenhams Pink and Solid White may be sown about the middle of the month in gentle heat to give early heads in September and October. Directly the plants appear above the soil, gradually harden them off, and keep near the glass to induce a stocky growth.

Couve Tronchuda or Portugal Cabbage is appreciated by some. Sow a pinch of seed about the middle of March on a warm border, and put out the plants later in rows 2 feet apart.

desirable; while the Cos section is well represented by Nonsuch, Superb White, and Mammoth White.

Radishes are much appreciated, and it is surprising what a quantity can be grown in a small space and without interfering with other crops, or even occupying separate ground, if, when sowing seeds of crops like Onions, &c., a little Radish seed is scattered with these. Sow little and often. Of all varieties, none is more popular than French Breakfast.

Spinach.—Long-standing Round and Victoria should be sown at intervals of three weeks, to maintain a choice supply of leaves.

Tomatoes for the open walls should be sown at once, to ensure the plants being strong and

sturdy by the end of May. Too often the plants are only 3 inches high when put out. In this case three parts of the summer is over before growth is sufficiently advanced to ensure a full crop of fruit; whereas, if the plants are at least 1 foot high and sturdily grown, they will quickly lay a foundation for fruit. Sow in gentle heat, pot off when large enough to handle, and grow on in a cool house close to the glass. Sunrise and Up-to-Date are good sorts.

Turnips should be sown often and in small quantities. Early Snowball, White and Red Milan, with All the Year Round are sufficient to provide all that is required in any garden.

E. MOLYNEUX.

Swanmore Park, Bishop's Waltham

THE NEW BRASSO-CATTLEYA SHOWN BY MR. F. M. OGILVIE, AT VINCENT SQUARE LAST WEEK.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Brasso - Cattleya Schröderæ Shrubbery Variety (Brassavola digbyana × Cattleya Schröderæ alba).—The sepals and petals of this handsome hybrid novelty are pure white, narrow and of considerable length. The heavily fringed lip is suffused with delicate pink, particularly near the sides, the yellow-stained throat throwing all into good effect. From F. M. Ogilvie, Esq., The Shrubbery, Oxford.

AWARDS OF MERIT.

Cattleya Olympus (Cattleya Octave Doin × C. Warscewiczii).—In this the sepals and petals are of rosy pink hue, the purplish lip somewhat heavily fringed with markings of yellow on either

side. From Messrs. Flory and Black, Slough.

Shortia uniflora grandiflora rosea.—The varietal names are fairly descriptive of what is undoubtedly the richest-coloured form of this species we have seen, the warmth of the rose, as well as its depth, surpassing anything hitherto seen in this singularly small genus. The newcomer is at once a beautiful and choice plant, destined to rank high among first-class alpinists. We hope it will be forthcoming in plenty. From Mr. Amos Perry, Enfield.

The foregoing were shown before the Royal Horticultural Society on the 2nd inst., when the awards were made.

Cucumbers for frames should be induced to grow sturdily by sowing the seeds singly in small pots in a brisk heat at the end of the month, transferring the plants to larger pots, so as to have them quite large, yet vigorous, at planting-time. Telegraph is still one of the most reliable varieties to grow.

Lettuce, both Cos and Cabbage, should be sown at intervals of a fortnight in drills 1 foot apart; then, should the weather be unfavourable for planting out, the plants can be thinned, leaving them a few inches apart, when they will quickly be ready for use. This plan is a great saving of time. Of Cabbage varieties, Earliest of All, Golden Ball and Favourite are

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Watering Fruit Tree Borders.—No hard-and-fast rule need be laid down as to watering fruit borders inside. Indeed, it is very dangerous to do so, especially when the borders are unusually deep. First ascertain if they are really in need of it; then give them a thorough soaking. Vines or Peaches which have just been started into growth should not require any water till growth is active. At this period lukewarm water must be given.

Peaches.—The final thinning of the fruits in the early house should not be delayed when stoning is finished. One fruit to a square foot of space is generally considered a fair crop to leave on trees which are in good fruit-bearing condition. All surplus growth must be removed so that the fruits have plenty of light, and also that the remaining growth has ample room to develop. One shoot at the point and one at the base of the fruiting wood will be found enough to furnish the trees with young wood. During the final swelling of the fruits plenty of stimulants must be afforded, and if not already done, the roots should be mulched with farmyard manure.

Plants Under Glass.

Carnations.—The plants which were propagated in December should now be sufficiently well rooted to be repotted into $4\frac{1}{2}$ -inch pots. Pot fairly firm and use a compost of loam, naturally decayed leaf-mould and coarse sand. Place them near to the glass and keep rather close for a few days, syringing them twice daily with rain-water during bright weather. Pot on cuttings as soon as they are rooted, but they must not be exposed to the sun or cold draughts till they have recovered from the shift. A few of the most forward of the Malmaisons may be placed in a warm house if a few early flowers are desired, but the main batch must be kept as cool as possible.

Cinerarias.—These will now have their pots well filled with roots, and must be frequently examined to see if they need water. Stimulants must be frequently given to assist the flower-buds which are now expanding. If the leaf maggot is present on the leaves, they must be picked off, or they will badly disfigure the plants.

Calanthe Veitchii.—The soil should be prepared for potting these, so that it may be in good condition when the pseudo-bulbs begin to emit roots. I find the plants thrive splendidly in a compost of fibrous loam, naturally decayed leaf-mould, dried cow-manure and coarse sand.

Euphorbia jacquiniæflora.—Plants which have been resting may now be placed in a warm, moist house to produce cuttings for propagation. They will require little water till growth is active, but they must be syringed frequently.

The Flower Garden.

Lawns.—The mowing-machines must be got ready for use, for it will soon be necessary to run them over the lawns. The lawns should, however, be well brushed with a Birch broom and rolled before using the mowing-machine. When the grass is poor, an effort must be made to improve it, either by dressing it with a mixture of fine soil and manure, or by using a special lawn manure supplied by the trade. The ground for new lawns should have its final preparation by making good any irregularities on the surface. The first favourable opportunity ought to be taken to sow the seed. The work of trimming the edges of lawns and grass verges should be brought to a close at once.

Edgings of Box.—Edgings of Box may be made now, either by cuttings or by young plants from the nursery. If cuttings are used, care should be taken to obtain them from trees of good habit and colour. Gaps in Box edges may be made good in the same manner.

Shrubberies.—The pruning of trees and shrubs should be brought to a close as soon as possible, so that the vacant ground in the shrubberies may be cleaned and dug. Trees which are supported with stakes must be examined, and the ties and stakes made good where necessary.

The Rock Garden.—Interest in this part of the garden will increase now that the growth of the plants is developing. Many bulbs and other

subjects are showing their flower-buds, and a careful watch must be kept for mice and slugs, or disappointments will be great. Any planting of hardy subjects not yet done should be no longer delayed.

The Hardy Fruit Garden.

Nuts.—These may now be pruned. Little need be done in the case of old established trees beyond a judicious thinning of the branches and the removal of suckers from the base. Younger trees must be carefully pruned, so that shapely, well-balanced trees may be grown. A point which needs emphasis is to have the centres of the trees open.

Figs.—The present is a suitable time for planting Fig trees outdoors. A warm, sheltered position must be chosen, such as a wall facing south or west, and a restricted rooting area is essential. In preparing the compost for the border, a good proportion of old brick rubble is necessary. Make sure also that the border is efficiently drained with broken bricks.

The Kitchen Garden.

Onions.—The plants that were raised in boxes for planting out will need pricking out into other boxes, in order to have strong plants by planting-time. Keep them rather close for a few days to encourage fresh roots; then gradually inure them to cooler conditions.

Leeks.—The earliest-sown plants may be treated as advised for Onions. A sowing may now be made outdoors for the main plantation.

Beet.—A small sowing of the Turnip-rooted kind may be made on a warm, sheltered border as soon as the soil is in suitable condition.

French Beans.—Make fresh sowings of these every ten days or a fortnight. Plants coming into bearing must be liberally fed with manures, and sprayed two or three times daily to keep them clean. A sowing may be made now in a cold frame.

Plants in Frames.

Cauliflowers and other plants which are being grown in cold frames for putting out in the open next month must not be coddled. During favourable weather the lights should be removed altogether. Pay particular attention to watering.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Fruit Under Glass.

Strawberries.—The later batches of Strawberries, after fruiting, should have any runners removed and be placed in cold frames. If red spider is at all evident, the syringe must be used freely. As the pots are likely to be required for other plants, it is an advantage to plant out as soon as the plants have become hardened to the cooler conditions. If the season is a good one, a second crop is very likely to be gathered during September or October from plants treated in this way.

Ventilation.—Exercise caution in admitting air to fruit houses at this season, especially if the top ventilators should be unfortunately facing the north, as is sometimes the case in the older structures. Close the ventilators fairly early in the afternoon, so as to retain as much sun-heat as possible.

The Hardy Fruit Garden.

Protecting Fruit Blossom.—Plums and Pears are very liable to be injured by frost and cold winds. Any extra work in arranging for their protection is usually well repaid by a better crop of fruit. Trees growing on walls are much more easy to protect than those growing in the open, for obvious reasons. Branches of evergreens, such as Yew or Spruce, are splendid for this work, as they can usually be made to remain on the spurs of the trees without much tying. Too dense a covering of any protecting material, however, is not to be recommended, as the blossom must be left exposed in such a way that it will receive the full benefit of the sun. If tiffany or any such covering is used, it will be necessary to remove it daily, and, whenever possible, keep it dry, as a dry covering will keep out much more frost than a wet one.

Plants Under Glass.

Salvia splendens.—If plants have not already been propagated, some cuttings should be got in and rooted in heat. If standards are desired, plants raised from seed will be found to make good long stems quicker than those from cuttings. The leading growth must be supported by a stake and disbudded until the desired height has been reached. Being a vigorous grower, *Salvia splendens* benefits from frequent applications of liquid manure.

Deciduous Calanthes.—With the exception of the very late varieties, such as *Regnieri* or *Sanderi*, all the *Calanthes* are sufficiently advanced to repot. When removing the old bulbs and soil, see that enough roots are left to secure the bulbs in the new compost. A good mixture in which to grow *Calanthes* consists of new leaf-soil, chopped *Osmunda* fibre, dried cow-manure, good fibrous loam, a little sphagnum moss, and a fair quantity of coarse silver sand.

Tuberous Begonias.—For a general summer and autumn display indoors, the tubers should now be started in gentle heat. Place them among leaf-soil in shallow boxes, in which they root very freely. Potting up can be carefully done after they are nicely started. Propagation of most varieties may be done by division of the tubers as soon as the small growths can be discerned.

Begonia Gloire de Lorraine.—This plant is now almost indispensable in every garden, being so useful for general decorative work. To have plants in various sizes, the propagation must be periodical; for instance, small plants suitable for table decoration should not be propagated until the middle of May. As plants become ready for potting, see that the soil is light, and do not pot at all firmly. Fumigate frequently to keep in check the various pests that these plants are subject to.

Campanula pyramidalis.—Both blue and white forms make handsome flowering plants for a display in July and August. Sow seed in heat to produce plants which will flower in 1916. Established plants may now receive some help from liquid manure as they commence to throw up their flowering stems.

The Kitchen Garden.

Rhubarb.—It is possible to have a good supply of Rhubarb quite three weeks in advance of the main crop, even without lifting the roots. To obtain this, any barrels or large boxes which have had the bottoms removed may be used. Place these over the crowns and surround them with some fresh stable litter mixed with a few leaves.

Peas.—More sowings must be made as the ground becomes ready. If possible, sow on ground which has been well manured the previous year; that which has been occupied by Celery will suit them well. Peas also do admirably on any new land, provided it is first well trenched.

Celery.—The main crop should now be sown in heat. Sow in boxes, and make certain that the plants never suffer from want of water, otherwise they are liable to run to seed later in the season.

The Flower Garden.

Pyrethrum aureum.—The sowing of this plant for bedding purposes should not be delayed after this date, as it requires a fairly long time to grow. Seed should be sown in boxes and put in gentle heat.

Mignonette.—To have this fragrant flower early, sow now in boxes, so as to have good-sized plants ready to put out in May, and which will commence flowering in June.

Pentstemons in frames, which have not been potted up, may be lifted carefully and dealt with in much the same manner as advised for *Violas*. Not being quite so hardy as *Violas*, they need more protection until they recover from the check caused by removal.

Calliopsis or Coreopsis.—The annual varieties are most graceful in whichever way they may be used for bedding. Sown outdoors, they do not flower until the season is far advanced; therefore, to get early flowers and better plants, seeds should now be sown indoors in boxes. Apart from being useful as bedding subjects, the flowers of most of the *Coreopsis*es are invaluable for cutting purposes.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

ROSE-GROWING IN TOWN GARDENS.

(Continued from page 113.)

Potash helps considerably in the formation of all plants. Its presence in the soil is essential to growth, for it combines with other elements in enabling the roots to assimilate food, and, as it were, promotes digestion. It also plays a considerable part in ripening the growths. Sulphate of potash is the most concentrated form generally used. Kainit is an impure form of the same salt (about one quarter the strength), and those who find difficulty in obtaining it should have recourse to wood-ashes, which form the best and cheapest substitute; or they can use nitrate of potash with caution.

Phosphates are chiefly instrumental in assisting in the production of fruit and flowers, and also aid in the formation of hard wood. It will be understood, therefore, that their presence in some form is indispensable to the Rose-grower. When forming the beds, bones are applied, and these form a lasting and slow-acting source of supply. Subsequent dressings of bone-meal in the autumn are very beneficial. In chalky soils dissolved bones should be given, as the presence of the lime retards decay very considerably. Guano, if of good quality, is particularly rich in phosphates, and is in itself a capital all-round manure, for it contains nitrate and potash in addition. It should be applied in the spring, about two ounces being given to the square yard. Superphosphate of lime contains a high percentage, and is perhaps the best form of adding phosphate in combination with other artificial manures. Basic slag is slow in action, and though sometimes advocated as an autumn dressing, other forms are preferable for Roses. It must not be mixed with sulphate of ammonia.

Lime, as is generally known, sweetens and improves the soil. It assists chemically in making other food available for the roots, besides forming in itself a part of the plants' nourishment. It helps also to retain nitrogen (ammonia) in the soil. Slaked lime should be added to heavy soils, pulverised chalk to lighter ones, when making up the beds. Sulphate of lime, otherwise gypsum, or plaster of Paris is the best means of adding it in conjunction with other fertilisers. Used with kainit, this has the effect of releasing the potash and making it available for the roots more quickly.

Iron assists in forming chlorophyll, the green colouring matter in the leaves, and its presence also intensifies the colour of the blooms. In many soils a sufficiency is present, but if it is desired to add it, sulphate of iron should be given.

Magnesia.—Roses contain a larger proportion of this than most plants, and its addition in the form of sulphate of magnesia, or Epsom salts, is generally advocated. Its main function is to assist in the formation of the protoplasm (the live part of the cells) and in the creation of fresh growths.

Perhaps the best formula for an all-round fertiliser for Roses is that known as Tonk's Manure, which is given below. Apply now at the rate of a handful to the square yard.

	Lb.
Superphosphate of lime	12
Kainit	10
Sulphate of magnesia	2
" " iron	1
" " lime	8
	33

It will be noticed that no nitrates are included, but if the foregoing is given now and, say, sulphate of ammonia is added in May, this will have the best effect. P. L. GODDARD.

ANNUALS AT READING AND SLOUGH.

FOR many years now we have had the privilege and pleasure during the summer months of inspecting that remarkable set of annual flower trials with which Messrs. Sutton and Sons make gay some fifty or sixty acres of their seed trial grounds near Reading, though never before do we remember wandering amid such a feast of colour—such flower pageantry, with all the colours of the rainbow in sumptuous array—as was witnessed on the occasion of a visit on July 31 last. And what is it all for? What does it all mean? Naturally, to take the last first, it means an enormous outlay of time and money, represented by the thousands of annuals that here find place, every one of which is labelled, booked in duplicate if not beyond, inspected over and over again during the season by the firm's own staff; these are among the items which go to make so gigantic and complete a trial. A "trial" as understood by Messrs. Sutton is an exhaustive as well as comparative test—a somewhat costly undertaking.

But what is it all for? Well, if we are to believe what we hear of the people we meet in the train, it is intended to be a flower show, though that is a low estimate indeed of the fact. That there is a flower show none will deny, but it is here as a consequence of the trials, and not for purposes of display alone. The one great object of this array of flower wealth is, as already hinted, a comparative test, and from out of it year by year Messrs. Sutton are enabled not only to select the most promising strains, but, while adding to the rich store of knowledge they already possess, impart this to their patrons and friends through the valuable medium of high-class seeds. Here, then, in nutshell form are the primary reasons for these wondrous displays, and if from the spectacular standpoint they are in the nature of a gigantic flower show, demonstrating high excellence in the flower garden and how it is obtainable at comparatively small cost, they are also intended for a much higher purpose of which the ordinary observer knows but little.

As to the display itself, or the items which go to make it, our remarks must of necessity be brief, since a volume as sumptuous as the display might well be written concerning it. To those interested in extensive ribbon borders of annual flowers we might at the outset refer to the borders at either side of the main drive at Reading, alike in view from the London Road and from the Great Western Railway. These borders are some two hundred yards or so in length, and their make up should interest gardeners, park superintendents and others who have to undertake such work. The borders are treated in five lines, and in this instance probably display was a first consideration. The first line at the margin was of *Alyssum maritimum*, a very good strain; the second, *Nasturtium The King*, of very intense colour; the third, *Godetia Dwarf White*; the fourth, *Godetia Scarlet Queen*; and the fifth, *Godetia Marchioness of Salisbury*. In this way fine colour

contrast, graduated height from front to back, and profuse flowering were all assured. In another direction a remarkable mosaic, created by the planting of the firm's special mixture of Dwarf Tom Thumb *Nasturtium*, attracted notice, so uniformly blended that almost every plant might have been put in its allotted place. As it was, the seeds were sown in the open, a fine tribute to the infinite care exercised in blending certain mixed strains of flower seeds. We have more than once been impressed by the beauty and truthfulness to colour of the Snapdragons, and we refer again to them because of their simple cultural requirements, their amenability to many classes of soils and their responsiveness to the gardener's art. Rich and pale apricot, Fire King, Orange King, Coral Pink, Rosy Queen, yellow of varying shades, bright and deep crimson—these are a few of the many that appear in each of the three sections—dwarf, medium and tall—of this unique, free-flowering race of hardy plants. Some of the more brilliant colour effects were created by the Malopes and Lavateras, and whether as hedges, lines or massed battalions, these plants made themselves conspicuous both by flower beauty and informality. *Lavatera Loveliness*, to name but one, was laden with its rich deep rose-coloured flowers on stems 3 feet high. It is a remarkable plant. *Calendrinias* and *Dimorphotiecas*, all sun-lovers, were finely represented, making gay pictures withal, the latter now seen in a variety of hybrid mixtures as well as in the handsome orange colour of the best-known species. A remarkable plant here among 3-feet-high growing subjects is *Datura ceratocaulon*, also known as Angels' Trumpet Flower. It has huge trumpet-shaped, white, shaded pink, exquisitely fragrant flowers, which are both picturesque and handsome. These, naturally, are but a fragment of the acres we saw at Reading.

At the Slough grounds we also found much to interest and instruct, and much food for thought. Sweet Pea flowers were in a decline; a very satisfactory crop of seeds—a heavy one indeed—in the ascendancy. Hollyhocks from February-sown seed were at the time of our visit (July 31) just beginning to show flower, a fine lot of plants that will prove invaluable for late work. We have rarely seen so healthy a batch, and, remembering the dryness of the early part of the year, progress had been remarkable. In the Slough soil, however, there is something for a plant to revel in, and obviously these Hollyhocks had discovered it. Quite one of the outstanding features here, however, was an acre or two of the new developments in annual Sunflowers, to which Messrs. Sutton are giving marked attention. Collectively they are a surprising lot, full of promise as a new race of garden plants of high merit, a veritable surprise packet to all who have yet to try them. The original cross (*Helianthus lenticulatus* var. *coronatus* × *H. annuus*), made by Professor Cockerell of the Colorado University, produced Sutton's Red Sunflower, a remarkably handsome variety of velvet brown, tipped golden yellow. Sutton's Bronze King, not yet absolutely fixed, is nearly self-coloured; it is almost wholly of brownish velvet hue. It is a selection from that first named, and quite unique. Langley Gem, Langley King, Langley Pearl, Langley Diamond (a cross between Sutton's Red and *H. cucumerifolius* Stella) and Langley Beauty, all distinct, serve to show the progress of the race at the moment. The plants, 5 feet or more high, are like a small edition of the annual Sunflower

(*H. annuus*) minus its greater coarseness, the flower-heads some 6 inches or 7 inches across. They are garden plants, however, and must be seen there; we cannot do them justice on paper. For the rest we were confronted by acres of Stocks, Asters, Lupines, Clarkias, Eschscholtzias revelling in the sunlight, Canterbury Bells, Iceland and allied Poppies (among which chaste and pretty art colours are now appearing), Marigold (*Calendula*) Orange King, and Cosmeas, than which none are more graceful and elegant, all giving of their splendour and, while affording pictures of varying and contrasting brilliancy to the landscape around, demonstrating their simple cultural needs by their responsiveness to field culture and the perfection to which they attain.

E. H. JENKINS.

BOOKS.

Gardening for Beginners.*—It has been frequently asserted that the publication of works on gardening has been too rapid for assimilation, and that a reduction in the output might with advantage be adopted. That this is not the case with books of a certain standard is, however, effectively proved by the publication of a sixth edition of the popular "Gardening for Beginners," written originally by Mr. E. T. Cook, and first published in 1901. It speaks much for the plan and execution of this book that it should have held the field for so many years, and that the publishers have found it necessary to re-issue it from time to time.

The sixth edition has been greatly revised and extended, and Mr. F. W. Harvey, to whom this has been entrusted, has carried out this troublesome task with rare ability and discretion. "Gardening for Beginners" retains all its first value, with the addition of many features which constitute it more than ever a *vade mecum* for the class for whose benefit it is written—a class difficult to provide for, inasmuch as the experienced gardener is apt to take for granted that the reader has much more knowledge of the subject than he really has. The result is that he too frequently writes above the level of the reader he hopes to assist, and the latter suffers accordingly. In this work, however, Mr. Cook struck an appropriate note, and in the process of revision and addition Mr. Harvey has acted in thorough accordance with the plan. This does not, of course, imply that "Gardening for Beginners" is only of use to the mere tyro in horticulture. It caters for him, but it also supplies much material of high value for those who are several stages more advanced, and, indeed, for many who have spent their whole lives in constant touch with horticulture and have practised it for many years.

In the sixth edition a very considerable improvement has been effected by the addition of some new chapters embodying instructions regarding several of the gardening features which have come into prominence since the earlier editions appeared. These have been admirably written, and the beginner will find in the book practically all he may require to ease his path in the formation and maintenance of his garden for many years.

* "Gardening for Beginners: A Handbook to the Garden," by E. T. Cook, sixth edition, fully revised, with additional chapters by F. W. Harvey. One volume, pages x.—350, including index, with many full-page and other illustrations and coloured plates. London: Published at the Offices of *Country Life*, 20, Tavistock Street, Covent Garden, W.C.; and by George Newnes, Limited, 8—11, Southampton Street, Strand, W.C. New York: Charles Scribner's Sons. Price 12s. 6d. net.

A careful perusal of these new chapters, which comprise such subjects as "The Heath Garden," "The Wall Garden," "The Paved Garden," "The Bog Garden and Its Formation," "Replanting or Renovating Borders," &c., reveals sound teaching conveyed in a manner which cannot be misunderstood, and rendering these pages of exceptional value.

The searcher after a manual of gardening is apt to suppose that he must purchase several books in order to cover the various branches of horticulture, and that he cannot well obtain one of moderate size, and at a moderate price, which will give him the instruction he desires on flowers, fruit and vegetables alike together with information regarding soils, manures, pests and other questions which crop up from time to time in the course of the garden year. Not only are these discussed—and that fully—but the greenhouse and conservatory, Ferns, the cold greenhouse and other features receive pithy, yet adequate treatment. It is, indeed, difficult within the limits of a review to select for notice any special feature, seeing that the whole field of horticulture as it appears to the beginner is well covered. Even the town gardener, who has difficulties all his own, in the dozen or more pages specially allotted to him in this handsome book of 650 pages will find a capital *résumé* of the subject and a stimulus to his attempts to make his *rus in urbe* a little pleasaunce amid bricks and mortar, as so many have done.

The general scope of "Gardening for Beginners" is a wide one, as may be gathered from the headings of a few of the chapters in each of the three parts in the volume. The first deals mainly with the flower garden in its various phases, and gives capital descriptions of different groups of hardy flowers, such as the Anemone, Pyrethrum, Delphinium, &c. The mixed border, with its treatment, is then discussed, and is followed by chapters on "Hardy Flowers from Seed," "Annuals," "Spring and Summer Bedding," "Sweet Peas," "Bulbous Flowers," &c. "The Rock and Water Garden" is fully considered, and "Good Trees and Shrubs," "Lawns," "Climbing Plants" and other subjects find full scope. Part II. deals mainly with glass structures and their inmates, and a good word may be spoken for the chapter on "Orchids for Beginners." The Chrysanthemum is also discussed, and even the curious Cacti find their place. Part III., which includes, *inter alia*, the cultivation of vegetables and fruit, written in a practical and concise manner, embraces a variety of other useful chapters too numerous to detail, but it may be said that it includes one of the many intensely valuable features of the book—a selection of plants, embodied in useful tables and lists, full of information. A study of these shows that they are well up to date, and they should prove of inestimable value to the busy gardener, whether he be professional or amateur.

In addition to the many improvements and additions in the letterpress in this edition, its attractions and value have been much enhanced by the addition of a large number of new illustrations in black and white, and also by some coloured plates, which not only brighten up the volume, but are also excellent examples of modern colour-printing. The whole "get-up" of the book is capital, and the price for a work of its size and quality is very small. It may confidently be commended to the amateur who desires to make the best of his garden.—S. ARNOTT.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. At reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artists' or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ORIENTAL POPPY DISEASED (*Papaver*).—It is scarcely safe for us to recommend treatment of a diseased plant without having an opportunity of inspecting it. We suspect your *Papaver* was attacked either by a bug which pierces the stem somewhat in the fashion of a cuckoo spit insect, or by the larva of a fly. We should, however, be glad if you would send us a specimen if the trouble should recur. In any case, the removal of all parts that are left above the ground would be a wise measure.

TREES AND SHRUBS.

SHRUB FOR NAMING (*Emile Thibault*).—The specimen sent for identification is the common Bay (*Laurus nobilis*). The seeds are quite typical, and the variation in size and shape is not uncommon in the species. The outer coat of the fruit has either rotted away or been eaten by birds.

ROSE GARDEN.

MOVING ROSES IN APRIL (*Miss G. Leney*).—Yes; you can safely transplant as late as April the Roses you planted in the autumn, and they will do all right, although they will bloom a little later. If possible, have the plants dug up now and heeled in on the north side of a wall or fence. Prune hard back at the time of replanting or immediately afterwards, and if the weather happens to be dry at the time, water them in and also apply water every five or six days for two or three weeks. When replanting, dip their roots in some thin mud and apply a shovelful of nice compost rather on the dry side. After the Roses have been planted a week, go over them and make the soil firm about their roots by pressing your heel on both sides of the plants.

ROSES FOR EAST WALL (*M. S. W.*).—Roses succeed extremely well against an east wall, and many lovely kinds may be grown there. We have Irish Elegance against such a wall, the plant being now some 6 feet to 7 feet high. You do not mention the height of your wall. If lofty, you would require rather strong growers. Perhaps to plant a tall grower and a moderate grower alternately would be best. As a rule, ramblers are best grown in the open, but there are some that have glistening foliage that succeed well. We note you desire pale colours as a contrast to the Phlox border close by. Below we append a list of early and late flowering ramblers that we can recommend. We also give a list of perpetual flowering kinds that we think should predominate. Ramblers (early).—Tea Rambler, Alberic Barbier, Gardenia, Leon-tine Gervaise, Shower of Gold and Desiré Bergera. Ramblers (late).—Elise Robichon, Paul Transon, Fran O. Hesse, Tausendschön, White Tausendschön, Miss Helyett, Silver Moon and Joseph Liger. Perpetual flowering (tall growers).—Climbing K. A. Victoria, Mme. A. Carrière, Bouquet d'Or, Mme. L. Constantine, Lady Waterlow, Gloire de Dijon, Climbing Clara Watson and Claire Jacquier. Perpetual flowering (medium growers).—Alister Stella Gray, Irish Elegance, Gustave Regis, White Maman Cochet, W. R. Smith, Mrs. H. Stevens, Papillon, La Tosca, Pharos and Marie van Houtte.

THE GARDEN.

No. 2261.—VOL. LXXIX.

MARCH 20, 1915.

NOTES OF THE WEEK.

Dainty Iris for the Rock Garden.—Of the most suitable Irises for the rock garden, *I. sind-jarensis* is one of the best. This charming little hybrid is derived from crossing *Iris sindjarensis* with *I. persica*, and is just now looking very pretty. It is very fertile and exceedingly floriferous, forming a close mass of blue. The foliage is intermediate between the parents, while the flowers are of a fuller form than in the female plant, but without the shaven apex of the falls that is so conspicuous in *I. persica*.

Cyclamen pseud-ibericum.—This is the finest of all the hardy members of the genus. It is of somewhat obscure origin, having been described from plants growing in the nursery of Messrs. Van Tubergen of Haarlem. Apparently a hybrid, so few seeds have matured on the plant. The leaves, like those of *C. ibericum*, are marked with a zone of white; instead of being entire, the margin is wavy, while the inner sides are of a ruddy rose colour. The rich rose coloured flowers, with the faintest tinge of purple, are produced well above the foliage, as may be seen in the illustration. The segments are about an inch long, and each has a dark purple blotch at the base. *C. pseud-ibericum* commences flowering early in February, and continues in bloom for nearly six months. It is quite as hardy as *C. ibericum* and *C. hederifolium*, but is much superior to either in the size of its flowers.

Supplies of Wood for Pits.—The Board of Agriculture and Fisheries desire to draw the attention of owners of woodlands and others to the fact that some collieries are still finding difficulty in securing adequate supplies of pit-wood. In consequence of the situation created by the European war, supplies from abroad are considerably curtailed, and it is necessary to have recourse to home-grown timber. Landowners may find this a favourable opportunity to sell, at a remunerative rate, timber of which they have hitherto found it difficult to dispose to advantage. As a rule, however, collieries are not prepared to buy standing timber unless the woods are in their immediate neighbourhood. Information as to the kinds of timber

required, marketing and other matters in this connection will be found in Special Leaflet No. 17, copies of which may be obtained post free on application to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W.

The False Acacia as a Hedge Plant.—In dry, arid soil, where the common Hawthorn will not succeed as a hedge plant, and only the most miserable of stunted, moss-covered plants exist, the False Acacia (*Robinia Pseudoacacia*) should be planted, as it will be found to thrive better than many kinds in such a position, and quickly forms a strong fence.

Abbey, created a record at the Forced Bulb Show in London last week, when he secured three gold medals for Hyacinths. These were awarded respectively for a group arranged for effect, eight pans of Hyacinths, and eighteen single plants.

Help for Aged and Infirm Gardeners.—The appeal that we publish on the next page from the Gardeners' Royal Benevolent Institution deserves, and we hope will receive, the fullest consideration of every one of our readers. We have intimate knowledge of the most valuable work that this Institution has done, and is still doing, and

can, therefore, advise our readers to render it all the assistance they can. Now that our gardens are awakening from their winter sleep and becoming beautiful with spring flowers, let us remember those who have in the past done their best to give us these pleasures, and who, through no fault of their own, have fallen on evil times. A sovereign subscribed to this Institution will give as much pleasure to one of these as the Crocuses and Daffodils bring to those who love beautiful flowers.

Home-Grown Vegetables and Our Food Supply.—The deepening interest which is being shown in this matter is a source of gratification to us. Since the appearance of the article in our issue of February 6, a London daily paper is offering £1,000 in prizes for vegetables, the Royal Horticultural Society has issued a circular letter on the subject, our contemporaries have "got busy" on vegetables,

and even some of the big London stores are waxing enthusiastic on the subject. What concerns us most, however, is the fact that a great many horticultural societies throughout the country are adopting the ideas set forth in our article, and it is from these that we consider the most valuable results will accrue. As will be seen by a letter we print on the next page, the Colchester Rose and Horticultural Society, which had decided to abandon its show, intends, mainly as a result of our suggestions, to hold a special show in September next. We repeat that we shall be pleased to send reprints of the article for distribution to anyone who cares to apply for them.

CYCLAMEN PSEUD-IBERICUM, THE LARGEST FLOWERED OF ALL THE CYCLAMEN HARDY IN THIS COUNTRY.

French Horticulturists in War Time.—We think the following extract from a letter received a few days ago will be interesting: "The French people, and French horticulturists especially, are deeply indebted to their British *confrères* and brothers in arms. I think I may say that both nations were glad to know each other better, and that the feeling of sympathy which the present war could only greatly reinforce will last for ever after the coming victory.—G. GRIGNON, *Revue Horticole*, 26, Rue Jacob, Paris (6e)."

Three Gold Medals at One Show.—It would be interesting to know whether Mr. James Gibson, gardener to the Duke of Portland at Welbeck

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Undesirables in the Rock Garden.—Re paragraph on page xxx in the issue for the 6th inst. on undesirable plants in a rock garden, I had two very undesirable ones, viz., Bindweed and Coltsfoot, to master when I first came here, and they had apparently come to stay. I cut each stem level with the ground and applied one drop of nitric acid. It was a long job, as there were hundreds of plants to deal with, but I have never seen them again.—ALBERT ERNEST HALL, *Southwell, Notts.*

Roses Under Glass.—Here are seven of the newer Roses for those who are compelled to grow them under glass—all have done extremely well in a cold house in pots, and in an atmosphere frequently likened to that in an old and, alas! over-populous world: Ophelia, Carine, Mme. Jules Bouche, Lady Greenall, Melody, Mrs. Amy Hammond and Mrs. Herbert Stevens. By the by, can anyone direct me to a Pernetiana Rose of good form that will retain its colour when cut?—TOWN, *Bury, Lancashire.*

Home-Grown Vegetables and Our Food Supply.—My committee met on the 5th inst. (adjourned annual meeting) to consider the question of arrangements for 1915. After considerable discussion, and in face of a motion that "No shows be held in 1915," it was eventually decided to hold a show on Wednesday, September 8, instead of the usual summer show in July. This decision was largely owing to the advice and information given in your excellent article, "Home-grown Vegetables and Our Food Supply," which appeared in the February 6 issue, and I have been asked whether you could help us by sending me sufficient copies of your reprint of the article for me to send one to each of the members of our society—about 250. If you can do this, I am sure they would serve a most useful purpose, and, further, explain better than I can not only why we are holding a show, but how each individual member can help.—JOHN E. CHEESE (Hon. Secretary), *Colchester Rose and Horticultural Society.*

Recipe for Orange Marmalade.—In your issue of March 6 "Anne Amateur" kindly contributes what appears to be a very good recipe for Orange marmalade—no doubt tried and proved by many a housewife. But may I crave space to point out a little omission or error which might lead to most serious consequences? The writer says, after giving directions for cutting up the Oranges very thinly, "Put the Oranges into the preserving pan with the water, leave them twelve hours to soak. Then boil for an hour and a-half after it boils up," &c. It should be pointed out most distinctly that no fruit of any kind should ever be left to stand in a preserving pan for any time if the preserving pan is of copper or brass, but only when the pan happens to be an enamelled one and in perfect condition—that is, with none of the enamel chipped off. The action of fruit, acid Oranges especially, would be to draw out the poison from the vessel, and a sad catastrophe might be the result. Moreover,

as Seville Oranges are naturally bitter, the poison drawn out (which is very bitter) might not arouse suspicion in the young and inexperienced till too late. The best way, in any case, is to leave the cut-up fruit in an earthenware basin till it is time to boil it. Young and amateur cooks cannot have it impressed too strongly upon them never to leave any food in copper or brass vessels, except during the actual process of cooking, after which the utensils should at once be cleansed and dried and put away.—N. COBB.

Phloxes for Spring Planting.—I was interested to read the excellent article on the spring planting of Phloxes in THE GARDEN for March 6, page 115. Although I would prefer autumn planting wherever possible, I have had good results from planting early in March, and send you a photograph, taken at the end of July last year, of a plant of the white variety Mrs. E. H. Jenkins. This was planted early in March last year, and I think

A WELL-FLOWERED PHLOX THAT WAS PLANTED IN MARCH, 1914.

the results are sufficiently good to justify one moving it at that time. What I do find, however, is that one must have good-sized plants. The small ones sold in pots give very little in the way of flower the first year unless planted in the autumn, —A. B. ESSEX.

The Gardeners' Royal Benevolent Institution.—The committee of management of this national horticultural charity make an earnest appeal for the means necessary to maintain their 265 annuitants, 150 men and 115 widows, costing nearly £5,000 annually. This amount, which is now urgently solicited, has been hitherto to a great extent obtained from donations and subscriptions kindly given at the Anniversary Festival Dinner in aid of the funds, which has been held without intermission each year since 1843. Now, however, in consequence of the terrible war in which our country is engaged, the committee, after anxious deliberation, have decided that

it would not be in accordance with the views or wishes of their friends and subscribers to hold a festival dinner this year, and instead they have determined to issue this special appeal for necessary monetary help, with the sincere and strong hope that those supporters who have so generously and liberally contributed to the Institution in normal times will not withhold their benevolence at this critical juncture, but will do their utmost to enable the committee to continue to make provision for the poor, aged and infirm people now under their care. It may be mentioned that one of these persons, a man, is now in his ninety-eighth year, while a widow has just completed her hundredth year. It is for these and the other unfortunate horticulturists the committee most earnestly plead. Subscriptions or donations, a list of which will be announced later, will be very gratefully received by the treasurer, Sir Harry J. Veitch, F.L.S., V.M.H., 34, Redcliffe Gardens, S.W.; or by the secretary, Mr. George J. Ingram, 92, Victoria Street, Westminster, who will gladly forward further particulars of the work.

Tropæolum speciosum.—One is continually coming across people who complain that they cannot grow this lovely Tropæolum in England. They say that they, and friends of theirs, have tried it again and again, but with no success. Here (North-east Lincolnshire) it flourishes splendidly, running over Ivy, Plum trees, or on a wall, and spreading in a wonderful manner. Perhaps the history of my plants may be of use to some of your readers who want to grow it; also the experience of an old friend of mine in Suffolk. In my case I originally bought two small plants in pots, and planted them (in early spring) about two yards apart on the north wall of my house. From the house wall a high wall runs facing west. The wall of the house is not due north, but north-north-west, and on the west wall is a large Victoria Plum tree; then a door through the wall, reached from the west by a paved path; then other fruit trees, continued on the west wall. The two plants did well, and soon began to run up the Ivy. The next stage was the appearance of small growths, like suckers, to right and left of the original plants, which also gradually began to climb, even up the Plum tree. Since then its running roots have spread right under the paved path, and

great growths of Tropæolum are now running up fruit trees, appearing quite 30 feet from the nearest original plant on that side, while many growths, though not so strong, are doing fairly well in the other direction. I have taken up and given away many pieces of the root from beyond the paved path, which, as a rule, have done fairly well, but it seems to have had no effect in lessening the growth here. My friend in Suffolk had a good hedge bordering a lawn. He planted several pieces of the Tropæolum on the north side of his hedge, which grew, and in summer made his hedge a very beautiful sight. Ours is strong soil; his was very light. I believe the whole secret is that *T. speciosum* must have moisture and be protected from strong sunshine; at any rate, till late in the evening in summer. Get an established plant in a pot, plant it on a north or north-west wall, and take care that it does not (in its early stages, at any rate) suffer from want of moisture—L. C. R. N. E.

Some Green Sandwiches.—Besides Mustard and Cress, which, like the poor, are always with us, one can have just now young leaves of French Sorrel, seedling Dandelion and Lettuce, grown and cut like Mustard and Cress, and young leaves of "Jack by the Hedge," so well known to French cooks and unknown or despised in England. Its Latin name is *Alliaria officinalis*. I sow this "weed" in my hedge every year for this purpose, and also for its usefulness in stews, soups and salads later on.—ANNE AMATEUR.

Freesias from Guernsey.—After reading in THE GARDEN the very able and interesting article contributed in your issue of February 20, pages 89 and 90, by Mr. J. Duncan Pearson of Lowdham, we thought it might interest you to see a bunch of *Freesia refracta alba major* and compare same with a bunch of *Freesia refracta alba* as imported from France. We congratulate Mr. Pearson on his cultural notes, and quite agree with him as to the principal causes of failure. We ourselves grow some hundreds of thousands, and can corroborate every word in favour of early planting. There is no good reason why *Freesias* should not be all potted up by the end of July.—W. MAUGER AND SONS, Brookdale Nurseries, Guernsey. [The flowers sent under the name of *refracta alba major* were large and good, and the stems considerably longer than those of *refracta alba*. Those sent as *refracta alba* were not that variety, but the typical *refracta*. We understand this often happens with bulbs imported from France.—ED.]

The New Zealand Flax.—With regard to the soil the New Zealand Flax likes (see page 50 issue January 30), it seems to me that none of the varieties is particular. I grow *Phormium tenax purpurea* and *P. t. variegata* on a decidedly clay soil. The latter flowered and seeded last year, and though the former has not yet flowered, it is nearly seven feet high, though the last fall of snow decidedly marred its beauty. The soil is geologically called brick earth, and it is on a south slope, where I can grow most things, such as *Eschscholtzia Stauntonii*, *Chamærops Fortunei*, *C. humilis*, *Dasyllirion gracilis* and other half-hardy plants. I have also grown *Cupressus funebris* and *C. sempervirens*. This season *Eschscholtzia Stauntonii* has kept its wood. *Ixias* have seeded with me, and all conservatory *Fuchsias* except *F. fulgens* and its hybrids and *F. arborescens* do out of doors. Even those *Gladioli* I have tried make new bulbs and come up again, so there must be something in the soil that suits them.—C. D. LANGWORTHY, Claygate, Surrey.

Ivy for Damp Walls.—Referring to the use of Ivy for covering damp walls, mentioned on page 97 of THE GARDEN for February 27, there would appear to be two distinctly opposite views of the question. The house that I am now living in is an old brick one facing south, and when I came into it some twelve or thirteen years ago I found part of the front covered with a thick coating of Ivy from the ground to the roof. I soon found that the wall of the dining-room, against which the Ivy grew, was exceedingly damp, so I decided to have the Ivy removed, which was not a very difficult task, as it came away in huge sheets some 2 inches or 3 inches thick, composed of matted and interwoven roots and having the appearance of a thick, soddened blanket or felt. Since then I have had the Ivy kept regularly cut back, so as to prevent any lodgment of water, with the result of a dry inner wall. This, I think, proves that with care in preventing the roots getting matted, and keeping it well clipped to

let in air, Ivy may be beneficial; but it must never be neglected.—J. R. J.

Mr. Cuthbertson and Antirrhinums.—I was interested to read in THE GARDEN for February 20 a review of Mr. Cuthbertson's book on Sweet Peas and Antirrhinums. In the review it is said that "Another point in favour of the Antirrhinum is that up to the present it has not been subject to any serious disease, though in America we believe a species of fungus rust causes considerable trouble." For the last two or three years we have been unable to grow Antirrhinums with any success owing to a spot disease that attacks the leaves and stems. A year ago I sent specimens to THE GARDEN for examination. I was told that the plants were suffering from the fungus *Septoria Antirrhini* and that this fungus was apparently spreading over the country, as many complaints had been made. I was advised to spray with potassium sulphide. This I did at intervals from the time the seedlings were small, with, I regret to say, very little success. I have lost most of my summer-sown plants, some varieties having quite gone out, and in several gardens near I have seen plants attacked in the same way. I should be very glad if Mr. Cuthbertson can tell me if this is the American disease, and if there is any prevention and cure.—E. K. POTTER.

Wallflowers in Pots.—The value of Wallflowers in providing a floral feast as spring bedding plants is familiar to most of us, but it is worth while considering their merits as pot plants also. When we realise that well-flowered specimens may be obtained early in the New Year, and that at but trifling expense, it would certainly appear as though this popular subject is worth a more extended use for the embellishment of the conservatory than it at present receives. The culture is simplicity itself. Sow the seeds in the ordinary way as for bedding purposes, and then, when large enough to handle, prick out the seedlings in rows 1 foot apart and allow 6 inches between the plants. It is best, however, to only allow a medium depth of soil, as this tends to prevent the roots "wandering" too deeply, and naturally enables the plants to be lifted for potting with the root-balls more intact. It is quite immaterial to a few weeks when this is done, but for the main batch of plants the early part of November does well. No special compost is required, and 4½-inch pots will accommodate really large plants. After potting, they should be kept in a cold frame until the roots have thoroughly "gripped" the soil, and then it is safe to begin gently persuading them to "move" a little in a cold house. No stimulant is necessary until the flower-spikes show, when one of the many approved foods certainly aids if applied weakly at every third watering. There are so many excellent varieties now offered that it is almost presumptuous to name particular ones, as I feel sure nearly all the varieties would respond to pot treatment for flowering. However, having thoroughly proved three, I will make bold to mention them. They are Carter's Old Gold, height about fifteen inches; Sutton's Fire King, the same height; and Webb's Kinver Favourite, which is a few inches taller.—H. TURNER, Serlby Gardens, Bawtry, Yorks.

FORTHCOMING EVENT.

March 30.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1 p.m. to 6 p.m. Lecture at 3 p.m. by Mr. Thomas Stevenson on "Chrysanthemums in Pots." Royal Horticultural Hall, Vincent Square, Westminster.

SEASONABLE NOTES ON CARNATIONS.

Border Varieties.—The past winter has been one of the worst possible for autumn-planted Carnations, the almost continual moist weather having seriously crippled the less robust varieties. These are usually broad-leaved sorts, such as Leander, Lady Hermione and yellow-blooded kinds. After removing the withered and damaged foliage, which is best effected by means of a pair of scissors—a knife, though ever so sharp, being liable to loosen the plants—the beds should be hand-weeded, hoed when the surfaces are sufficiently dry, and a dressing of manure, such as soot, pigeon or poultry manure, or superphosphate of lime, evenly applied. Those plants that are obviously too much weakened to do any good should be replaced by reserves; but it is often seen that very weak plants, provided the soil is nicely fertile, grow into good material by flowering-time, so that some caution must be exercised in eliminating at least the more expensive or rare varieties.

Introducing Novelties.—The present is a suitable time to introduce novelties or varieties that need reintroduction, for Carnations in some soils, or perhaps more truly in some climates, are apt to degenerate, and a change of stock when degeneration occurs is imperative. Though unpotted layers are best to purchase in the autumn, it is better at this season to go to the expense of obtaining plants thoroughly established in pots. These do not suffer at all from drought, as plants lifted from the open do. Even home-grown Carnations take to the soil much quicker if transferred from pots than do those which have been bedded in frames, no matter how good the "ball" may appear.

Plant Early.—The very earliest opportunity to plant should be embraced. Plants are now beginning to grow, and late spring transplantation has on that account a weakening influence, owing to root action being checked for a time. In large gardens, where there is usually space for a number of beds, Carnations are undoubtedly best grown *en bloc*, reserving free growing and flowering varieties, such as Raby Castle and Henry Falkland, for grouping in mixed borders.

Soil Preparation.—Provided the ground was prepared in the early winter, or, better, in the autumn, preparatory work at this time will consist in re-digging the surface a few inches in depth to make doubly sure of every lump of soil being broken, and if it is considered necessary, some quite rotten manure, or in heavy soil a very liberal dressing of rough leaf-soil, incorporated at the same time. Lime is always of value, and a sprinkling of powdered lime may be very advantageously applied to the surface previous to planting. Though beds to be planted in the autumn should not be quite level, but slightly rounded, at this season the ground should be level. The beds are marked out by dividing the ground into foot spaces, missing every fifth or sixth, which provides an alley for getting at the plants and flowers. Longitudinal lines bisect these, and a plant is put in at the point of each intersection. Some kinds of plants do well, and perhaps all the better, if rather deeply planted.

Carnations, which are sub-suffruticose, resent deep planting, and this is a point that cannot be too carefully attended to. It is to be expected that no one would dream of planting until the

SECTION OF WATER LILY TUB AT K IN
"ROSE COTTAGE" PLAN.

soil has become moderately dry, and, that being the condition, after planting is finished the soil should be firmly compressed by foot pressure. Every plant that is likely to be blown about by high winds should have a short stick applied and the plant be fastened to it, and, of course, the soil, in conclusion, must be neatly hoed to cover footmarks.

R. P. BROTHERSTON.

TWO COTTAGE GARDEN PLANS.

HINTS FOR DESIGNING VERY SMALL GARDENS.

It has been suggested to us that plans for laying out very small gardens belonging to semi-detached cottages would be useful, and we have therefore asked Mr. Dillistone, who, of course, is generally occupied with much larger designs, to furnish the following:

A question often asked is, "What can be done with a garden about 60 feet or 70 feet long and 25 feet or 30 feet wide?"—such gardens, in fact, as are provided with the usual semi-detached suburban villa. Quoting from a letter recently received,

"Now this is the most miserable garden to tackle." It is a fact that the conditions are not inspiring, and that gardening effort usually begins and ends with digging a narrow border round the outer bounds and maintaining a more or less unsatisfactory plot of grass in the middle. In presenting to readers the accompanying plan for two such gardens, I hope I shall succeed in showing them that even such small plots, devoid of any element of interest as they apparently are, can be made capable of providing a very great deal of interest, varied treatment and pretty effects.

"**Lavender Cottage.**"—First we will consider the design and planting of "Lavender Cottage." On the right, entering the gate, Border A is more or less essential, and is a line fixed by the building arrangements, because the whole width left between the house and fence is not required for a path. There are many ways of planting it that will make a cool and pleasant approach to the house. Of course, there must be a few creepers on the fence, Jasmine or Honeysuckle, for instance. The border will be in partial shade, being on the north-west side of the fence, and is, therefore,

eminently suitable for planting Ferns. Lastreas, Athyriums and Polystichums would all do well therein, and a pretty idea is to plant spring-flowering bulbs among them, such as Scillas, Crocuses and Grape Hyacinths, especially such as will flower about the time the young Fern fronds are beginning to unfold. The soft, delicate greenery of the Ferns lends an effective groundwork for the colour of spring flowers. For a later effect, some of the shade-loving Lilies can also be grown, and their blooms, rising above the Ferns, are enchanting to the eye. The stem-rooting varieties of Lilies enjoy such a position

flowers and annuals. I shall later give a suggestive list of plants suitable for this border, indicating by the numbers shown in the plan the positions for each. On the other side of the wall should be planted a simple border of Lavender, preferably one of the dwarf-growing varieties, because they are more suitable for a small garden. *Lavandula spicata nana compacta* is a good variety. Carpet the ground under the Lavender with purple Aubrietias, among which plant spring and autumn Crocuses. All of these will thrive without being disturbed for several years, and such a border will be bright during the greater part of the year.

The Path itself can be of any material that is neat and dry. Bricks on edge are suggested in the plan, and as these quickly take on a rich brown red tone, are not offensive to the eye. In the crevices between the bricks some of the common, close-growing Sedums should be allowed to ramble. The centre of the path should be arranged to be at right angles to the house and central with the window. The whole effect is here designed, in fact, to form a picture from the window of what will probably be one of the most frequently used rooms in the house. Two (or three) weeping trees, such as Weeping Birch or the Golden Weeping Willow (*Salix vitellina aurea pendula*) will act as a screen to the beyond if it is unpleasant, or, if the distance is a pretty bit of country, the trees can be arranged so that they will act as a frame to focus the view on to such a scene. Between them is a suitable place for a simple seat, and the trees can be easily trained to form a sort of arbour.

An Interesting Feature in the way of a sundial, or vase planted with flowers, placed at D, will create a diverting and attractive break to the monotony of the lines. The planting of the remaining positions is clearly stated on the plan, and is

PERSPECTIVE OF THE WATER LILY TUB AT K.

because of the shade afforded to their roots.

At the end of this border a length of trellis will divide it from the back garden, rendering the latter as secluded as possible, and also enclose a small open space by the kitchen door. The archway through the trellis is so arranged that the view from the window at the back of the house is quite clear to the garden beyond. A few creepers can be trained on the trellis and over the archway.

Looking through the window, the eye will travel on through the archway down the path, on one side of which can be arranged a border of hardy

PLAN AT K IN "ROSE COTTAGE" GARDEN.

suggested because it will give a long flowering period at a minimum of expenditure. Moreover, all the plants are of easy cultivation. In the front garden the Border B should be reserved principally for sweet-smelling flowers, such as Mignonette, Rosemary, Night-scented Stock (Matthiola), &c., and as it is a pretty idea to make the garden live up to the name of the cottage, Lavender should be used freely everywhere. In C, plant a few of the smaller-growing flowering shrubs. In the

“Rose Cottage” garden the scheme is entirely different. Beds E, F, G, H and I should all be Dwarf Polyantha or China Roses, or can be omitted altogether and left as grass. Climbing Roses should be planted to train on the house and over the archway, with which can be mingled Clematis. Border J can be treated as described for A, because in this case the house will cast a shade. The planting of the principal borders will, of course, be a matter of individual taste, but the scheme for the large border at “Lavender Cottage” can

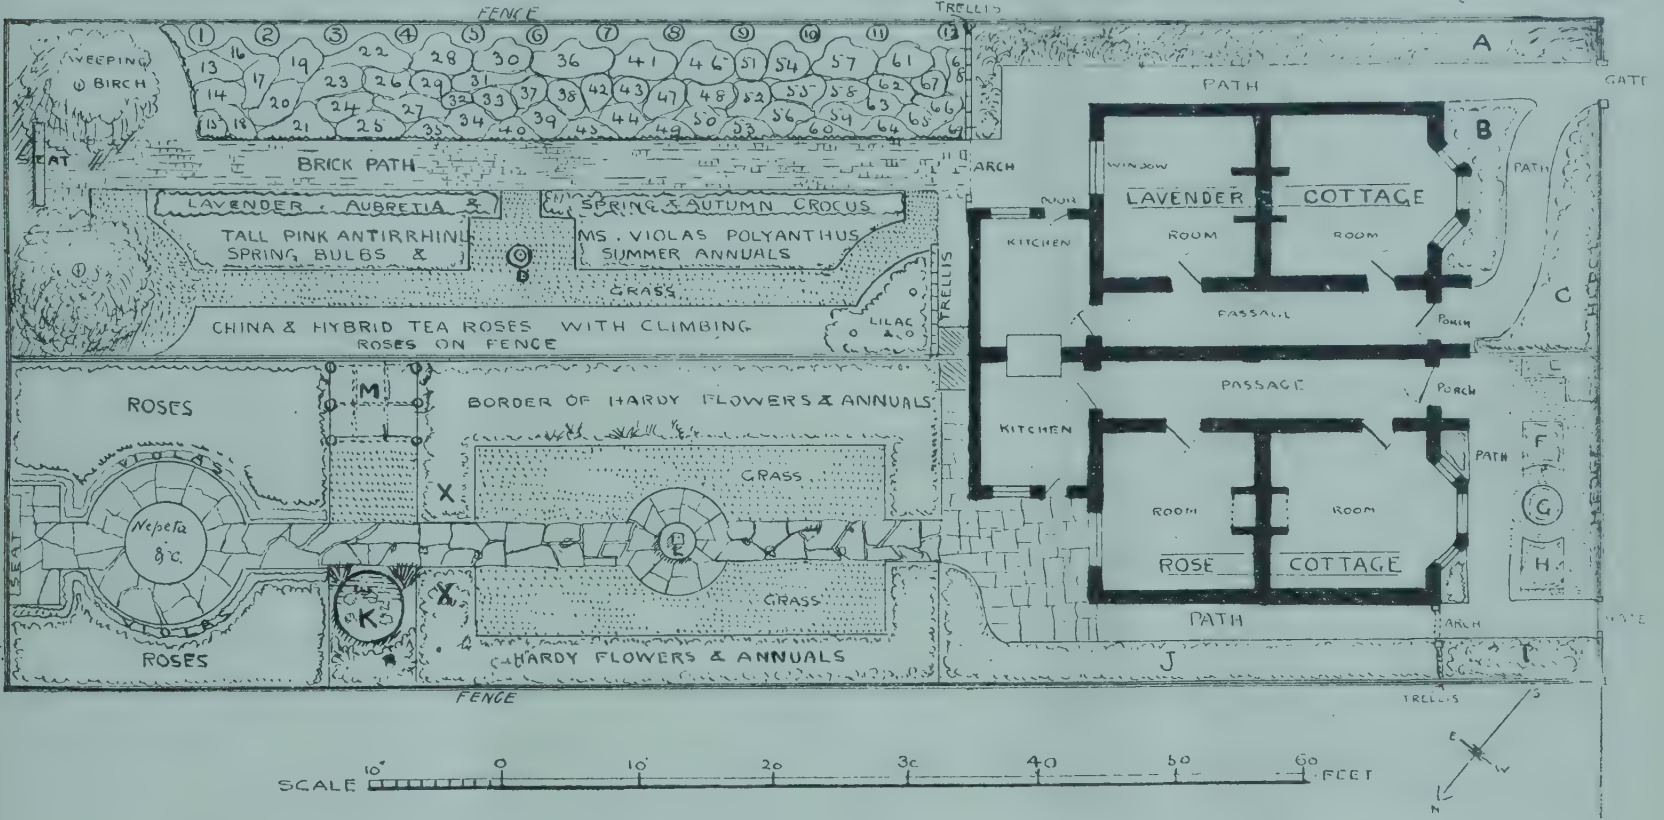

Thymes, Sedums and other miniature forms in the interstices between the stones. In studying the planting of the borders, one point is worthy of particular attention. In the “Rose Cottage” garden, where marked X the grouping should be simple but distinct, bold and permanent. A suggestion for such a position is Saxifraga (Megasea) cordifolia on each side of the path, a Yucca filamentosa on either side, and surrounding it Linum perenne, mingling with pale yellow or pink Antirrhinums; but there are many other ways of obtaining the desired effect, viz., point, focus and perspective as seen from the window.

BORDER OF HARDY FLOWERS AND ANNUALS.

No. on Plan.	Name.	Colour.	No. of Plants.
1-12	Climbing Roses, Clematis and purple-leaved Vine alternately trained on stakes 6 feet or 7 feet high and festooned from point to point, but kept pruned very thin to give a light and pretty background to border flowers.		

No. on Plan.	Name.	Colour.	No. of Plants.
44	Aster subcaeruleus major	Grey blue	5
45	Cerastium tomentosum	Grey foliage	5
		white flower	
46	Delphinium Persimmon	Azure blue	3
47	Statice latifolia	Lavender	3
48	Scabiosa caucasica	Lavender blue	3
49	Aubrietia Lavender	Lavender	5
50	Gypsophila repens rosea	Pale pink	5
51	Lupinus polyphyllus	Blue	2
52	Campanula macrantha	Purple	6
53	C. muralis or pusilla	Blue	5
54	Hyacinthus candicans	White	9
55	Gladiolus Baron Joseph Hulot	Purple	6
56	Achillea Kellneri	Grey foliage	2
		white flower	
57	Iris asiatica	Blue to purple	5
58	Aster Thompsonii	Lavender	3
59	Phlox Dr. Charcot	Violet	3
60	Stachys lanata	Grey foliage	5
61	Aconitum Spark's Variety	Violet blue	3
62	Chrysanthemum maximum	White	3
63	Campanula carpatia alba		3
64	Iberis Snowflake		3
65	Viola gracilis Purple Robe	Purple	6
66	Iris germanica violacea	Violet purple	6
67	Pæonia festiva maxima	White	1
68	Lilium candidum		6
69	Nepeta Mussinii	Lavender	6

It must be understood that this border is not arranged to what is generally termed a “colour

PLANS FOR TWO VERY SMALL GARDENS. THESE CAN BE MODIFIED TO SUIT ACTUAL REQUIREMENTS.

be easily adapted. At L, central with the window, place a simple vase, figure or sundial. K offers a position in which to indulge in a modest way in one of the most fascinating efforts of gardening. It is a tub about three feet across and three feet deep, partially sunk into the ground, and in which is planted one of the delightful pink or crimson Water Lilies. The details for this are given in the accompanying illustrations on page 136. M should be a Rose-covered arbour, made by training Roses over a simple construction of Larch poles. A Rose garden in miniature will terminate such a scheme effectively, and if the centre bed is planted with Nepeta Mussini, and pink Antirrhinums, and the Rose borders are edged with mauve Violas, the effect will not fail to satisfy the most fastidious taste.

In neither of these two schemes should the area of grass be less than shown in the plan, and if the central walk is paved, a softening effect can be introduced by planting some little Campanulas,

13	Achillea Ptarmica The Pearl	White	3

scheme,” except that at certain points provision is made for pretty colour groupings, such, for instance, as 39 (pink), 40 (lavender), 45 (grey and white), 38 (rose pink) and 33 (creamy yellow), and throughout it is attempted to arrange a border that shall give pleasing colour groupings and, as far as can be procured in such a limited area, a long period over which there shall be as much flower as possible. With regard to the quantities allowed, three plants, generally speaking, are equivalent to an established clump two years old. If the quantities are reduced to one-third, therefore, the ultimate effect will be the same, but this will not result until the second summer after planting. Many people prefer (on the score of saving expense, &c.) to plant more thinly, fill in the intervening spaces with annuals, and wait for full development. By a judicious use of common sense a great deal may be done in this way, and in planning a garden it must always be remembered that personal tastes have to be considered.

GEORGE DILLISTONE.

DAFFODIL NOTES.

BY THE REV. JOSEPH JACOB.

THE ROYAL HORTICULTURAL SOCIETY'S FORCED BULB SHOW.

THIS important two days' show was started very largely with the idea of giving Daffodils a chance of showing themselves, in a sort of official way, when grown in pots. Accordingly, one hoped to see a good muster of exhibits and flowers. On the present occasion the Hyacinth predominated and the Daffodil had to play second fiddle. For one reason I was glad, for on the principle of it being an ill wind that blows nobody any good, they were there to greet the three Dutchmen who, braving the

well grown, the varieties were nicely arranged, and there was sufficient diversity to satisfy everyone. At the expensive end of the scale there was an excellent example of White Emperor, which is now priced at twelve guineas a bulb; and at the other I noticed Autocrat and John Bain, both splendid pot plants which can be bought for a few shillings a hundred. A vase of Homespun not far away from Autocrat made me wonder which of the two the general public would like best as a decorative flower. There is very little doubt that the public and the specialists do not see eye to eye. For example, as I was writing my notes I heard some people "cracking up" Mrs. H. J. Veitch, while Cornelia, which was close by, attracted no notice. The vase of Van Waveren's Giant was splendid. I do not think I ever saw it finer. The new Poetaz, Admiration,

Messrs. J. R. Pearson and Sons' blooms lacked size. I wonder if in their case good, hard, single-nosed bulbs were selected as far as possible. It might make the whole difference. As was to be expected, the Lowdham Giant Leedsii's were very much in evidence, and we had a good opportunity of making comparisons, for, odious as they so often are in the everyday affairs of life, among Daffodils they are necessary. Capella, which I noticed more than once last year, struck me as a very pretty little bloom, on account of its refined trumpet-shaped corona. Margaret, a good-looking 1B (white trumpet), was one of the newest flowers on this stand. It resembled Empress in its general look, but the perianth segments appeared both smoother and wider. I must not omit a good vase of Pedestal (a white incomparabilis). It is interesting to know that this late variety, like

A BEAUTIFUL GROUP OF FREESIAS GROWN BY MR. GENTLE, GARDENER TO MRS. DENISON, LITTLE GADDESSEN, HERTS.

German submarines, had come over to see the show. As I have said, the Daffodil compartment of my mind was disappointed; but as a general florist I heartily endorse the remark of Mr. Thomas Stevenson of Sweet Pea and Chrysanthemum fame, who told me he thought it was the prettiest and brightest of all the Forced Bulb Shows. May I say to our Daffodil friends who usually exhibit, but who from one cause or another did not do so this year, that we must not let the general public think that they can get on without forced Daffodils. There were three orthodox cut bloom groups—a small and select one from Inglescombe; a second, much more extensive, from Lowdham, but with blooms below par in size; while the "best of all the three" was Christopher Bourne's from near Bletchley (Bletchlee). This struck me as a very good exhibit indeed. The flowers were

showed up well; so did King Alfred and the old maximus. There were one or two novelties. The one that appealed to me was a small, cool-eyed variety called Lorna. It is a small pointed 2B (white-perianthed Barrii) with a large, cool-looking eye of pale greeny yellow with a distinct band of red. The perianth is pointed and reflexes slightly. The Swan is a drooping white Ajax with a long trumpet and a campanulate perianth. I was told that it is a robust grower and a very free bloomer. I was glad to have my own experience confirmed about the value of choosing single-nosed bulbs for potting when particularly good results are wanted. Mr. Chapman, who is Mr. Bourne's grower, told me that he has found this out from his own practical experience and observation, and that he attributed his well-grown display very largely to this.

Cleopatra (yellow trumpet), will respond to mild forcing. Mr. Walter T. Ware's two dozen contained several nice varieties under number. Of the named ones, there was a fine example of White City. A good bloom measures—D, 4; S, $1\frac{1}{4} \times 1\frac{1}{4}$; C, $\frac{3}{4} \times \frac{3}{4}$. It is a most distinguished-looking, small-cupped Leedsii, after the style of White Slave. White Cockade is a new pale double. It has ivory white guard petals and a large, pale citron cup, with the centre nicely filled with similar-coloured bits of converted stamens, from which a few long, white ears, like we frequently see in a double Snowdrop, protrude. I hope we shall see this flower again from the open. I know it attracted several people. Flash must also be noticed. It is a sort of giant Beryl, with a large, wide, reddish orange cup, and big primrose segments which reflex a good deal.

A last word must be about the delightful boxes on Messrs. Barr and Sons' exhibit, full of *minimus*, *nanus*, *Queen of Spain*, *Bulbocodium*, *citrinus*, &c., peeping out of moss. It was a very pleasing display, and it would be nice to see the plan adopted more generally for these small kinds.

Measurements. — No official order was adopted at the Narcissus committee, but after some discussion it was agreed that it would be well to introduce letters to make the measurements clearer. Thus, D will in future with me stand for the diameter of the flower; S, for the measurements of the *inner* segments, (1) the width and (2) the length; C, for those of the *corona*, (1) the length and (2) the width at the top. If under C only one number is given, it will be that of its width or diameter.

A MAGNIFICENT GROUP OF FREESIAS.

I ENCLOSE you a photograph of *Freesias*. The group was grown from 150 bulbs. I quite agree with Mr. Pearson, whose article appeared on page 89, issue February 20, that they ought to be grown a great deal more than they are. I always cover my bulbs with Cocoanut fibre, and leave them out in the open until they are 2 inches or 3 inches high; then put them in a cold frame. (I treat *Triteleias* the same, and they make a very nice edging to the *Freesias*.) In staking, I use Privet or Hazel twigs, as they are light and green and neat in appearance, as you will see. A. G. GENTLE.

Little Gaddesden, Berkhamsted, Herts.

THE SHIRLEY POPPIES.

THERE are few hardy annuals more highly appreciated for cutting than the modern strains of the Shirley Poppy, for which the world owes an everlasting debt of gratitude to the Rev. W. Wilks, the secretary of the Royal Horticultural Society. It is true that others have, since Mr. Wilks gave them the lead, improved the Shirley Poppy and given us a number of beautiful flowers widely divergent in colour, as witness those of slaty blue colour illustrated on page 85 of THE GARDEN for February 20. It is these charming art shades, combined with long, wire-like stems and beautifully crimped petals, that render the newer Shirley Poppies so valuable for indoor decoration.

They have one fault, however, viz., that the petals drop very quickly once the flowers are fully open. For this reason it is wise to cut them in the bud stage, just when the

coloured petals can be seen through the aperture caused by the division of the green sepals, and allow them to open in water. Then it is we see the dainty goffering of the petals to perfection.

Fortunately, these Poppies are quite easily grown. It is true they appreciate well-drained soil that

up much too thickly, hence early and rigorous thinning is necessary, the Shirley Poppy being by nature a robust and branching plant. Seeds of separate colours can be obtained if desired, or good mixtures if preferred. The illustration on this page represents a beautiful photographic study of white flowers. D. M. L.

WHITE SHIRLEY POPPIES AS CUT FLOWERS. SEEDS MAY BE SOWN OUTDOORS DURING MARCH AND APRIL.

SOME GOOD MOCK ORANGES.

AMONG the many hardy shrubs which flower in late spring, none has sweeter flowers than the Mock Oranges, or *Syringas* as they are often erroneously called. Until a comparatively recent date these were represented by large and rather unshapely shrubs that needed considerable space to show off their flower beauty to the best advantage. The introduction of a dwarf variety named *Philadelphus Lemoinei* some years ago was, therefore, of considerable advantage, and time has proved that this was but the forerunner of many of its class. These dwarf-growing Mock Oranges are excellent for planting towards the front of a mixed border of choice shrubs, or a large lawn bed may be filled with them, and the bed carpeted with *Scillas*, *Winter Aconites*, *Snowdrops* or other early flowering bulbous plants. Fortunately, these shrubs are not fastidious as to soil, providing it is well enriched with manure. As the best flowers are produced on wood of the previous year's growth, a good system of pruning is to cut the shoots back almost to the ground each year immediately the flowers have faded, and at the same time give a good top-dressing of partially decayed manure. This induces the formation of strong young shoots, which will flower the following spring. By adopting this method of pruning, the shrubs are always kept neat and compact, and can be used in many situations where larger and more robust kinds would be out of place. Among the most beautiful of these new dwarf Mock Oranges is that known as *Philadelphus purpureo-maculatus*. As its name implies, the four white petals of each flower have a purple blotch at their base, and this imparts great charm to the flowers. *Rosace* has large, creamy white, double flowers which are particularly fragrant. *Fantaisie* is a beautiful large single variety, some

of the flowers having a delicate pink tinge towards their centres. *P. Lemoinei erectus* is an older variety than those named above, and, as its name implies, is of erect growth. Otherwise it is a counterpart of *P. Lemoinei*, the flowers of which are pure white, very fragrant and of medium size.

is not over-rich, but, apart from that, they may be sown in almost any part of the garden, or even open spaces in the woodland, that one may wish. On very light soil, autumn sowing gives wonderfully good results, but in most gardens it is best to rely on March or early April sowings. Owing to the seeds being so small, the seedlings invariably come

SEASONABLE NOTES ON CHRYSANTHEMUMS.

AMATEUR cultivators throughout the country will now be engaged in the work of transferring the young plants to larger pots. As good results follow good work, as a rule, it is well worth paying close attention to that of repotting at the present time. The enthusiast rarely fails to spend considerable time over the work of final potting, but he sometimes does not, as regards the quality of the compost, give similar attention when carrying out intermediate repottings. A fibrous loam, forming the chief part of the compost, acts as a suitable medium, in which the roots will remain healthy throughout the season. A fibreless, sour soil is neither fit for the retention of the roots nor as a storehouse for stimulating foods which are given from time to time. So we see how important it is to provide a good but simple potting compost at all times. By "simple" I mean one that does not contain numerous kinds of ingredients, as sometimes mixtures that are really poisonous to the plants are prepared for them. Fibrous loam, sweet leaf-soil, horse-manure that has been prepared so as to get rid of the poisonous gases in it, sufficient coarse sand to ensure porosity, a small quantity of bone-meal and old soot will constitute a compost ideal for the plants at each repotting. The only difference will be in using it in a rougher state as the size of the pots is increased. At this stage there should be a reduction in the number of plants, assuming that more were propagated than will be required at the final potting. It is not advisable to keep more now, because they only take up valuable space, thus spoiling to a certain extent the chances of those retained, and entail needless labour.

How to Pot.—All the young plants will not be rooted to the same extent, so that it will be advisable to make a selection, first picking out those that possess the most roots. All will not require the same sized pot, because some are stronger than others, and the strongest must be placed in the larger pots. At each repotting till the final one the same plan should be adopted. Place one hollow-shaped crock on the hole in each pot, and a few small ones before putting in some of the more lumpy compost. Many crocks are not required; it is the manner in which they are placed that matters. Make the soil moderately firm with the fingers, but do not use a potting-stick at this stage.

Watering and Staking.—If the compost is in a medium state of moisture, water will not be needed for at least two days after the plants are potted. If the leaves droop, a light spraying will be beneficial. Then water thoroughly and wait

until the soil is approaching dryness before giving more. If the soil is kept in a saturated state, the plants will show more signs of distress than if it became rather dry occasionally. Loosely fasten the stems to neat stakes when the plants are repotted.

Position.—The cold frame is an ideal structure for the plants now and until they are hard enough to be placed outside. For a week or so after potting keep the frame rather close; then gradually increase the amount of ventilation.

Stopping Plants.—When it is necessary to stop a plant, the tip must be removed about ten days before the plant is repotted or ten days afterwards. Stopping plants always causes a check to their growth, and if the stopping is done

particularly noticeable during the evenings of hot days. If used as an edging, this ought to be at least a foot wide, anything less than this failing to give so good an effect. This *Alyssum* is quite dwarf, seldom growing more than 4 inches high, and I find it will thrive in almost any kind of soil.

G. B. D.

HINTS ON GROWING ASPARAGUS.

With good attention Asparagus will thrive in the same beds for many years, but, to keep up a supply of large, thick heads, new beds should be made at intervals, and only the best varieties ought to be planted. Giant French is a fine variety for the production of large heads; and Perfection, Connover's, Colossal and Purple Argentine will also be found excellent. The best time to plant the roots is early in the spring, just as the new growth commences; but the beds should be thoroughly prepared some weeks in advance. In the more unfavourable parts, and where the soil lies somewhat low, good drainage must be employed and the beds thoroughly trenched, adding as the work proceeds plenty of well-decayed manure and sandy loam, with a good sprinkling of salt. If, however, the land is naturally well drained and the soil of the right character, less preparation of the beds will be needed. I usually make the beds 4½ feet wide and plant strong, healthy crowns 1½ feet to 2 feet apart, so that each root may have ample room to develop and produce good results.

Those about to make new beds should set to work without delay, so that by the first or second week in April the soil will have somewhat settled before planting. First stake out the beds the desired width, using strong stakes and driving them well into the ground at each corner; then prepare the soil as above advised. Some prefer to raise their own plants from seeds, sowing a couple of packets of these annually. As, however, good

plants, two years and three years old, may be obtained at a low cost, to save time I would advise purchasing sufficient roots from a good firm.

If the plants are to be raised from seeds, have the beds in readiness, and when the soil is in a suitable state, sow in lines 18 inches to 24 inches apart and an inch deep. As soon as the seedlings are large enough, thin to the required distance in the lines. Keep the beds clear of weeds and encourage healthy growth. A sprinkling of salt at intervals or a dressing of suitable manure will prove highly beneficial to the growth of these plants. As the plants grow, take care to employ some kind of support to prevent the grass from being broken off at the collar in rough

PORTION OF A SMALL MIXED BORDER WITH A BROAD EDGING OF ALYSSUM MARITIMUM CARPET WHITE.

at the same time as the repotting, the check would be greater.

AVON.

A GOOD HARDY ANNUAL FOR EDGINGS.

In my opinion, one of the best hardy annuals for edging is a compact form of *Alyssum maritimum* named Carpet White. If seeds are sown thinly early in April they quickly germinate, and it is not many weeks before the seedlings form neat little tufts of greenery which, in due course, develop and form a complete carpet. The plants commence to flower quite early, and continue until autumn frosts call a halt. It is an annual much appreciated by bees, its honeycomb-like fragrance being

weather, as this would prove very detrimental to the roots.

Old beds greatly benefit by a few applications of liquid manure during the growing season, and by not cutting the heads too severely; also keeping the beds free from weeds, and the

can realise the pleasure in watching each seedling open its first flower. The majority will be "weeds" and of no value; but there is always that possibility of raising a "Derby winner," and herein lies the chief interest. I have previously referred to the various sections of Auricula; but it will be noticed that many seedlings will not conform to the rules as laid down by florists, and are in consequence "outsiders" or among the "a'so ran."

A Plea for the Fancy Auricula.—Now, those seedlings that do not fall into either of the orthodox groups are known as "fancy Auriculas," and every raiser should grow the best of his seedlings a second year, when a more thorough selection can be made. There will be many plants that will come under the above heading which possess much beauty, and are suitable either for pots or the open border. We have fancy Carnations and other plants; why not fancy Auriculas? It may make the Auricula more popular, especially if a few amateurs take up this section.

T. W. B.

HOW TO PLANT ASPARAGUS. NOTE THAT EACH CROWN IS PLACED WELL AWAY FROM OTHERS.

removal of a few of the weaker growths during the early part of the growing season.

Wrotham Park Gardens, Barnet. H. MARKHAM.

SEASONABLE NOTES ON AURICULAS.

DURING the month of March the Auricula-grower will become more interested in his plants, as some of the early varieties will begin to push up their scapes. The plants should be grown quite cool, and only sufficient protection given to prevent them from becoming frozen, as the Auricula never thrives in heat. The fact that it is an alpine subject should always be borne in mind, and for this reason cool and hardy treatment must be the rule if the best results are to be obtained. At this period of the year the weather will need watching, and on bright, warm days full ventilation may be allowed; but occasionally such days are followed by 8° or 10° of frost, when it will be advisable to close the frames and cover them with Archangel mats.

Fumigation.—Prior to the first flower opening I always vaporise the frames with XL All or some other reliable fumigant to kill any green fly that may be present. It is rather important that the fumigation be done before the flowers open, because the fumes take the colour out of the blooms; and should even a little green fly be on a few specimens, it spreads rapidly, and the plants would be thoroughly infested before the flowering season was passed. Some cultivators possess a cool, low house, and where such is the case the plants are arranged upon inverted flower-pots, so as to bring them near the glass and level with the eye, when their exquisite forms and various tints of colour can be seen to the best advantage.

Seedlings Flowering for the First Time.—When a man or woman takes up the culture of any particular class of plants, they very soon have a desire to raise at least a few seedlings each year. This is as it should be, and only those who have been engaged in this fascinating pursuit

HINTS ON PRUNING ROSES.

THE article upon pruning which appeared in THE GARDEN of February 28 dealt more especially with the early pruning of various sections, but the present notes will cover the ground more fully, and may be taken as an addition to the article just alluded to.

Columns have been written in the past upon Rose pruning, and yet it always seems necessary to return to the subject each spring. Not that the art has changed, but more because there are always a large number of new readers of THE GARDEN to whom the past notes may not be accessible.

It may be asked by the novice, "Why is it necessary to prune Roses?" I think I cannot refer my querist to anything better than to the wild Roses of our hedgerows. A study of these will show that the Briar annually sends up from its base new growths to maintain the youthful vigour of the plant, because, after about two years, the Briar growths gradually deteriorate, whereas the young shoots are the picture of lusty health. Our object in pruning, then, is to encourage new growth, and with many Roses, unless the old wood be eliminated, new wood appears very slowly. Certain tribes, such as the Hybrid Teas and Teas, are so full of vigour that they will send out fine new growths even though the old wood remains; but if the grower cuts away some of the old shoots,

the blooming from those remaining will be considerably improved. Of course, there is such a thing as rational pruning. Unfortunately, many have an idea that all Roses should be pruned alike, just as one would a Privet hedge; but a little reflection on the part of my readers will show them that the most vigorous growers require their new wood shortening the least, whereas poor growers need hard pruning, so that the energy of the roots is concentrated upon fewer eyes or buds.

Before I go into details I would just say that I consider the middle of March early enough to prune Hybrid Perpetual and most of the Hybrid Tea Roses, whereas the end of March and early April is best for the true Teas and allied tribes such as the Monthlies and Polyanthas. Readers in the South could prune a little earlier, and those in the North a little later. Many individuals are tempted to prune earlier than the time stated if they observe the plants sprouting, only to be cruelly disappointed to find that a frost in April has upset all their calculations.

The secateurs, if thoroughly sharp, are the most convenient tool to use, and an inferior pair should be at hand to cut out old or dead wood. Always, where possible, cut to an outward-looking eye, a detail that is important if we study the symmetry of our plants. When commencing to prune a plant, first remove any dead wood and any growths that exhibit signs of exhaustion. Often one may find thick, old growths partially dead on one side. I attribute this to injury by frost probably a year or two back. At the time it did not show the injury, but has gradually become less vigorous. Such growths are best destroyed, for while they remain they, to a large extent, prevent new growths from springing up.

Next remove soft, sappy wood, no matter how robust it looks. Such shoots will bend readily, and, if cut, will be found to be nearly all pith. Our aim must always be to have wood with the least amount of pith. Such wood is technically termed "ripe" or "matured," and it is hard and rigid.

Readers must understand that these notes are not written for exhibitors, but for those who grow

THIS ILLUSTRATION SHOWS HOW AN ASPARAGUS PLANT SHOULD BE SET ON THE SOIL BEFORE COVERING.

Roses for the adornment of their gardens; therefore, if any reader desires to exhibit, I would counsel him to prune more severely than what I recommend here. Although I give the approximate length that various groups should be pruned, I may say that there is no hard and fast rule. Let

each reader use his own judgment, bearing in mind the principles that should govern our pruning, which I have tried to explain. I have selected a typical variety of each section, which, if that variety be studied, will, I think, explain matters as fully as though I mentioned a greater number.

Hybrid Teas of the vigour of Caroline Testout may have their ripe shoots pruned back to about six eyes. If the eyes are rather prominent, then prune to a fairly dormant eye, even though it means pruning to the fourth or fifth eye. Small, thin shoots may be cut to two or three eyes. In all cases keep the centre of the plant well open and try to picture what the plant will be like when the new shoots develop. Some kinds of greater vigour, such as Avoca, may be retained fully a length of 15 inches to 18 inches, whereas those of the growth of Le Progrès may be shortened back to about four eyes, and laterals to about two eyes.

Hybrid Perpetuals.—These are pruned much on the same lines as Hybrid Teas. Varieties of the Hugh Dickson type must not be hard pruned, or there will be all growth and no blossom. Retain the shoots from 1½ feet to 3 feet in length; in fact, it is best to treat such Roses either as pillars or climbers, unless grown as standards, in which case the strong growths may be cut back to about ten inches or twelve inches, and the lateral growths to about three or four eyes. Varieties such as Fisher Holmes should be pruned back to about eight eyes on all strong growths, and laterals to about two eyes. With this tribe it is a good plan to cut out the old wood in September, and by all means let there be a severe cutting away of such old wood, removing it right to its base.

Tea and Noisette Roses.—Varieties of extra vigour, such as the two Cochetts, William R. Smith, Marie van Houtte, &c., should have the basal growths reduced to about ten inches or twelve inches, and the laterals to three or four eyes; while varieties of less vigour, such as Mme. Hoste, ought to be pruned back to within 4 inches to 6 inches. All decrepit wood, and that injured by frost, must be cut out. Frequently Tea Roses are partially injured by frost, which is manifest by cutting a shoot, when the pith will be brownish in colour. Such growths will send out new shoots in the spring, but will either fail in the summer or will never be a success. It is far better to eliminate them now. If in such a mild winter as we have had some shoots start early into new growth, one such growth to each plant may be retained a good length, to be afterwards cut away if desirable. In all cases it is the sound, hard wood that gives us the most perfect flowers. In the Southern Counties and in sheltered districts where Tea Roses grow so freely and it is desired to have an abundance of bloom, a very moderate system of pruning may be adopted, provided the plants are not overcrowded with shoots; but even in their case some of the older growths should be cut away annually in order to encourage basal growth; for it is from the base we obtain the growths that provide us with the glorious autumn crop of flowers, both of the Teas and Hybrid Teas. The new

Pernetiana Group is somewhat difficult to manage. I am inclined to do a very moderate amount of pruning. I have grown Lyon Rose and A. R. Goodwin on these lines, and have had much success. It all depends upon the winter whether we can do this, for, as a rule, Jack Frost is a ruthless pruner. Where the wood is uninjured, try just tipping the shoots, and remove one or two if the plant is very crowded. Roses of this group, such as Juliet and Beauté de Lyon, may have their

strong growths retained a length of 1½ feet to 2 feet. Some have treated them as climbers, and although we get more flowers, they are not nearly so large or shapely as when the varieties are fairly well pruned.

China or Monthly Roses are treated like the Tea-scented varieties, save the Old Pink Monthly, Fellenberg, Armosa, and the like. These may be simply thinned out and their last year's growth left almost unpruned.

Polyantha or Pet Roses, if wanted as big bushes, need very little pruning, save a thinning to avoid overcrowding; but where employed as bedding plants or as edgings, pruning to within 4 inches to 6 inches of the soil is best.

Rugosa or Japanese Roses, if grown specially for their berries, are best pruned back to 4 inches or 6 inches—that is, their last year's shoots; but if wanted as big bushes, then merely tipping them will suffice. Conrad F. Meyer is a prodigious grower, and I usually retain its strong growths 4 feet to 5 feet long, and laterals from 6 inches to 12 inches. Nova Zembla and Rose à parfum de l'Hay are treated in a similar manner, while Georges Cain, Mrs. A. Waterer, &c. are pruned like strong Hybrid Perpetuals.

Moss Roses.—Leave the annual growths from 1 foot to 2 feet long, and laterals to about six inches. Damask, Alba, Bourbon and Hybrid Chinas should have the annual growths left from 1 foot to 3 feet long, according to the vigour of the variety. All the Briar family require merely tipping, but old wood should be removed as it becomes exhausted.

Scotch Roses are not pruned in any way. They seem to revel in being left alone. Most of the

Rose Species require no pruning beyond removing old wood occasionally. Where possible, open these out by placing a stake or two around the bushes and tying the growths thereto. Some lovely species are simply spoilt if touched with the pruning shears, for the half pendulous shoots are most elegant when covered with glorious bloom.

Banksian Roses must never have the fine, spray-like shoots touched, but in June it is advisable to remove some old wood when the plants become too dense. These Roses love to have their shoots well roasted in the sun; then they will bloom freely enough.

Single Roses.—Many of the lovely single Roses, such as Irish Elegance, are spoilt by pruning. I never prune this Rose, and I have it on an east wall, with growths 6 feet to 7 feet high, also, big bushes 4 feet to 6 feet through, growing in the walks. Gottfried Keller is very impatient of pruning. Often the operation has been the means of killing the plant.

Standard Roses of the big-headed sorts, like W. A. Richardson and Gloire de Dijon, need very little pruning. It is best to tie over the growths in umbrella fashion and shorten the laterals to three or four eyes. Of course, here, as with all Roses, decrepit old wood must come away.

Climbers on Walls should have all the new wood possible laid in and, where practicable, in a half horizontal manner, relieving the trees of old wood to make room for the young. Lateral growths are best reduced according to strength, the strongest to 12 inches or 18 inches and the weakest to two or three eyes. It is essential to remember that all climbing Roses, whatever their class or tribe, flower best from well-ripened, one year old wood. That grand old Rose, Climbing Devonensis, is very impatient of being pruned. It is far better

to tie its shoots over in an arch-like manner. When planting such Roses, space should always be allowed for them to be trained out horizontally, more like a fruit tree. If this is done, the growths produce plenty of laterals, and if these are shortened to three or four eyes, then we obtain a fine crop of flowers.

Now I would say a word or two about unorthodox pruning. In a collection of Roses that once came under my notice, the owner changed gardeners, and the incoming gardener was one of those who believed in very moderate pruning. Well, the result was that sorts like General Macarthur and Joseph Hill were left practically untouched, and the owner had a glorious mass of bloom. But the Roses had been hard pruned the previous year; consequently most of the wood was one year old. Now, this was all very well for the one year; but how about next year? Why, there was comparatively little basal growth until very late in the year, and consequently it was very unripe, so that the next year the crop of bloom was very inferior.

Pruning First Season after Planting.—It is a severe trial to many amateurs to cut back their Roses nearly to the ground, but this should be done with all save very vigorous sorts, and even they are best pruned to 9 inches or 12 inches. Prune climbing Roses of the Tea and Hybrid Tea class to about two feet, save one or two exceptions. These would be the least vigorous, such as Climbing Mrs. Grant, Ards Rover, &c. I advise leaving these 4 feet to 5 feet long. If pruned to 12 inches they often fail to make long growths for some time. Ramblers of the Wichuraiana class need not be pruned much, but the Multiflora section are best cut back to about twelve inches.

Weeping Roses the First Year.—Prune the Multifloras back to 3 inches or 4 inches, but the Wichuraianas leave alone until after flowering; then cut away to their base nearly all the growths that have bloomed. This should be done in July, if possible, so as to ensure good long growths appearing before late autumn, as these long growths provide us with the crop of bloom next year.

DANECROFT.

SOME BEAUTIFUL BERBERIS HYBRIDS.

AMONG the many shrubs which flower abundantly in spring, none is appreciated more than the Barberry known as Berberis stenophylla. In addition to its flowering character, the narrow, rich green leaves are retained through the winter, and these, together with its drooping growth, render it ornamental at any time of the year. In the flowering season each slender branch is clothed with rich golden yellow flowers, and may be likened to an arched streamer of golden bells. Such a useful shrub as this has naturally received attention from the hybridist, with the result that there are several distinct forms of it obtainable. The most beautiful of all is that known as corallina, a name it derives from the colour of the flower-buds. These are a decided coral red, or in some instances scarlet, and, although the flowers are yellow when fully expanded, much of this colour of the buds is retained. The variety gracilis is worthy of attention, owing to its habit of producing flowers in autumn as well as in spring. Erecta is a small, upright-growing variety with pale green, spiny leaves. Irwinii is another dwarf variety, the rather arching stems growing closely one above the other. H.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Fig Trees in Pots.—The trees which were started into growth in December will soon be ripening their fruits. They will need plenty of stimulants from now till the fruits actually begin to ripen. A surface-dressing of rich farm-yard manure will also be of considerable benefit. The temperature at night may be kept about 60°, unless the weather is very mild, when 5° more may be allowed. Attend to the stopping and regulating of young growths, and see that the shoots are sufficiently thinned so that light and air may reach the fruits. When the fruits commence to ripen, discontinue syringing and keep the atmosphere on the dry side.

Fig Trees in Borders.—Old-established trees growing in shallow, restricted borders must be liberally treated if they are carrying full crops of fruit. If there are plenty of roots on the surface of the border, there is nothing better than a mulch of rich cow or horse manure to assist the final maturing of the fruit. This should be put on just prior to watering. Stop the shoots at the fourth or fifth leaf, and thin them out where they are too thick. Unfruitful wood may be cut hard back to encourage fresh growth at the base. Syringe the foliage vigorously twice daily, and damp the floors several times a day.

Plants Under Glass.

Plumbago rosea.—Cuttings of this beautiful stove flowering plant may be inserted now. They will root readily in a light sandy compost. Plunge the pots in the propagating-frame. During the season of growth the plants will require stopping two or three times to encourage a bushy habit. Some of the old plants may be repotted and grown on to make large specimens.

Ferns.—Now is a suitable time to repot those plants which are in need of it. Large specimens will thrive for several years in the same pots if they are given proper attention in regard to watering. All old fronds may be cut off, and, after repotting or top-dressing, place the plants in a warm, moist house. A suitable compost may be made of loam and peat in equal parts, leaf-mould, crushed charcoal and sand.

Forced Shrubs.—As these pass out of bloom, remove all dead flowers and prune those shrubs which need it. Lilacs may be cut well back and placed in a cool house for a week or two before planting them out. *Prunus triloba* is an excellent plant for forcing. After blooming, the old flowering wood may be cut back hard to induce the plants to make fresh flowering shoots. Azaleas may be repotted and placed in a warm house to complete their growth.

Heliotropes.—Cuttings rooted now will make nice plants for summer flowering. Young shoots taken from the old plants will readily root in pots or pans filled with a light sandy compost. Keep the young plants growing in a warm, moist house, and stop them occasionally to induce a bushy habit.

The Flower Garden.

Gladioli.—Where these are required for cutting, they may be planted now. Those required for planting with other subjects must be potted up and placed in a cold frame.

Marguerite Carnations.—The continuous flowering of these beautiful annual Carnations makes them invaluable for the flower garden. The plants must, however, be liberally treated, or they will prove disappointing. When the seedlings are large enough, pot them into 3-inch pots and keep them growing in a warm pit near to the glass. Afterwards harden them off in a cold frame.

Spring-Flowering Plants.—After the continuous heavy rains the soil between the plants will require to be stirred with the hoe; but this must only be done when the ground is dry. Herbaceous borders may be treated in the same manner. Where Tulips and other bulbs are growing in grass, the rank grass should be carefully cut with the shears, or it may smother the flowers.

The Hardy Fruit Garden.

Grafting.—Trees which were headed back a few weeks ago in preparation for grafting will

now be in proper condition for the operation. Rind or cleft grafting is the method usually adopted for established trees.

Strawberries.—Old plantations will benefit by dressings of well-seasoned soot being applied during showery weather. Keep the ground free from weeds and remove dead leaves from the plants. If a new plantation is contemplated, the sooner it is done the better. A new plantation should be made every year for the purpose of supplying runners.

Autumn or Perpetual Strawberries.—Seeds may now be sown for raising plants to fruit in the autumn. Sow thinly in boxes and place them in a warm house. Keep the young plants growing near to the glass, pricking out the seedlings into boxes when large enough. The young plants should be ready to put out early in May.

The Kitchen Garden.

Vegetable Marrows.—A sowing of these useful vegetables may be made now for planting in frames. Sow the seeds singly in 3-inch pots and place them in warmth to germinate.

Mint.—It is a good plan to lift and replant a portion of the bed every season. Dig into the ground some well-rotted manure and soot, and see that it is well cleared of weeds. Put out the young plants in rows about a foot apart.

Tarragon.—This should also be lifted every season, and if the ground is inclined to stiffness, a quantity of well-rotted leaf-soil should be dug into it. Carefully pull the old plants to pieces, and plant only the most promising portions in rows 18 inches apart.

Chervil.—A small sowing of this should be made monthly on a border which is not too much exposed to the sun.

Basil.—This valuable herb requires to be grown under glass. Sow in pans, and prick out the seedlings into 6-inch pots filled with a rich compost.

E. HARRISS.

(Head-gardener to Lady Wantage.)
Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Flower Garden.

Antirrhinums.—Any varieties which have been propagated from cuttings will now be ready for removing outdoors to some sheltered border, where they will remain until needed for bedding. Treat them in the same manner as Pentstemons. Young seedlings raised from seed sown during January should now be pricked out 3 inches apart in cold frames, keeping the frames shut until they recover from the check of removal. A slight shade during bright sunshine will also be of great help to them for the first few days.

Verbenas are easily grown from seed if sown now. They may also be propagated from cuttings, which root very readily with bottom-heat. As Verbenas, particularly some of the named varieties, are very subject to mildew while growing indoors, means must be used to prevent this.

Nicotiana.—Both the *Sanderæ* hybrids and the sweet-scented affinis should be sown now. If possible, pot up singly when the plants are large enough to handle.

Calceolarias.—Where space will allow, these should all be lifted and replanted in frames at a greater distance apart than when they were put in as cuttings. Add a quantity of leaf-mould and sand to encourage free rooting with a view to getting good plants for setting out in May.

The Rock Garden.—Now that most of the plants are beginning to grow, an opportunity should be taken to overhaul this garden, restricting some of the freer-growing subjects to prevent them overgrowing the small and more shy growers. Blanks ought to be made good, and the more tender subjects which have been wintered in frames may be got into their proper positions. Plants such as some of the *Primulas* are apt to become leggy, and these derive benefit from a top-dressing. Then there are usually parts of the rockery which have become washed bare of soil. This should be replaced and a general tidying up given.

The Kitchen Garden.

Early Peas.—The Peas which were sown indoors some time ago and have recently been growing in cold frames must now be got into their permanent positions, taking care that the site is well screened from north and east winds and yet receiving the full benefit of the sun. Whether the variety is tall or dwarf, the plants should be given the protection of some Spruce twigs or branches of a similar type.

Autumn-Sown Cauliflowers.—Now that the plants have been hardened off by the entire removal of the lights, it is safe to plant out. As a number may possibly button or bolt, they could be planted rather more closely than the late crop. As a safe protection against slugs, dust the soil immediately around the plants with soot. Early Erfurt is a reliable variety which matures quickly.

Globe Artichokes.—The protecting material should now be removed, a dressing of manure given, and the ground forked over. It is rather early yet to transplant, but where a new plantation is to be made, the ground must be got ready.

Broad Beans that were sown in boxes indoors must now be planted out. As the plants are naturally not so stiff and sturdy as those sown outdoors, they should receive some support as well as ample shelter, so as to give them a good start.

Jerusalem Artichokes.—These will grow on for years unheeded or untouched if the soil is fairly rich; but to get the best tubers a new plantation should be made each year. If the ground has been dug or trenched and manure added, they can be planted at once 18 inches apart, and 3 feet 6 inches to 4 feet between the lines.

Fruit Under Glass.

Melons.—The temperature in the Melon pits or houses must be well maintained. On no account must it be allowed to drop below 65° during the night-time. The atmosphere must be kept humid, closing the ventilators early in the afternoon so as to conserve as much sun-heat as possible. The plants should have the leading growths stopped when they are about two feet in length. Most varieties will be found to set more freely on sublaterals than on the first breaks.

Early Peaches and Nectarines.—The longest growths will be in need of tying, and should be attended to before they become too large. If the disbudding has not been sufficient, a few more growths may be cut out altogether, so that there may be no undue overcrowding. As the fruits are swelling, the chief thinning ought to take place, leaving, when possible, the fruits which are best placed above the wires. The heaviest and best quality fruit is obtained by severe thinning.

Plants Under Glass.

Summer-Flowering Zonal Pelargoniums should now be placed in their flowering pots. In all cases it is wise to restrict their rootrun by confining them to small pots, as they flower with far greater freedom in these than would be the case if given more room.

Stove Plants.—The potting of most stove plants ought by this date to have been nearly completed. Any arrears of this work should be attended to before growth is any further advanced. Pay close attention to shading and ply the syringe frequently, closing the houses early in the afternoon to secure all the sun-heat possible.

Malmaison Carnations.—Plants which were potted into 6-inch pots during October are now ready for shifting into 9-inch and 10-inch ones. For preference select plants which have been watered the previous day. The soil should be left rather rough, and must contain a large proportion of porous material, such as small charcoal, crushed brick and calcined oyster-shell. Also include clean leaf-mould with silver sand, and if wireworms or eelworms are troublesome, a small quantity of some soil fumigant may with safety be included during the soil preparation. If the potting compost is of the right texture, it will almost be impossible to pot too firmly. Malmaisons do not like moisture actually on the foliage, but constant syringing between the pots of newly potted plants is beneficial, except during very damp and dull days, when a drier atmosphere is best.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SPARAXIS PULCHERRIMA (*Antrim*).—This charming plant will be quite at home in any fairly open position sheltered from north and east. The soil should be made up of loam, peat, leaf-mould and sand in about equal parts, adding a fourth part of very old finely sifted manure. It would be best to prepare a special bed for it, with not less than a foot deep of the soil mixture—better if 1½ feet—resting on a well-drained bottom. Moisture is of some importance during growth, and this it should not lack. In favoured places—for example, Guernsey and the Isle of Wight—the plant does well in rich, deep sandy loam; hence a warm position is something to aim at. The eighteen months old seedlings could be transplanted with impunity, though it would be best to get them into their permanent places during the present month.

ERIGERON QUAKERESS (*C. G. B.*).—The behaviour of your plant is very unusual, and we are somewhat at a loss to account for it, more particularly as the other species named does so well. As a rule, both flower freely and profusely in the majority of sandy and loamy soils, that named above frequently continuing till frost arrives. Obviously, some local influence, of which we have no knowledge, is affecting it. Should there exist lack of vigour of the individual crowns, it would be well to divide the plant freely in March, affording the divisions a richer soil when replanting. You say the plant "spreads about," and as its growth is more or less tufted, we wonder whether you have the true plant. If you have, we see nothing but lack of vigour to account for your non-success.

YELLOW-FLOWERED AQUATIC (*B. H. Lyne*).—If the plant referred to was small habited, we should conclude it to be *Villarsia nymphaeoides*, which would do moderately well in a tub of, say, 1½ feet to 2 feet deep, with 6 inches or so of loam and cow-manure to feed upon. The *Myosotis* is one of the most miniature growing of the alpine species, and prefers gritty loam in rocky crevices. It is one of those difficult subjects likely to be best suited in the moraine. The *Erpetion*—now known as *Viola hederacea* or the New Holland Violet—is an Australian species of doubtful hardness, though in your district it may succeed. The plant grows quite freely in loam, peat and sand in equal parts, and prefers a rather cool position. Planted out in a frame it rarely fails. You do not say where or how you have grown the *Soldanella*. Grow the plant in loam and peat, with ample moisture throughout its growing season. Drought is doom to it so far as its flowering is concerned. Try *Gentiana acaulis* in a more loamy soil freely charged with old mortar rubble or sandstone chippings. It should be very firmly planted, and right up to the base of its leaves. The plant prefers a deep and cool rootrun.

DELPHINIUMS IN SHADE (*A. E. A.*).—These plants among the Roses are somewhat out of place, as much by reason of growth when established as the conflicting nature

of their colours when in bloom. In the shaded position referred to they are not, if removed thither, likely to prove a permanent success, though they might do for a time. Much depends, however, upon the nature of the shade, and distant tree shade would be much less harmful than cold, uncongenial shade, the product of near-by buildings or high walls. Of these things you will be the better judge on the spot. For the moving and transplanting, March is quite good, though big clumps of these planted intact are rarely a success. In other words, when the clumps are large, dividing and replanting should go hand in hand.

TREES AND SHRUBS.

NAMES AND TREATMENT OF SHRUBS (*Mrs. Lönemann*).—The purple-berried shrub is the Coral-berry (*Symphoricarpos orbiculatus*), native of the Eastern United States. It can be pruned back fairly severely at the present time. The other plant is *Cupressus lawsoniana* var. *albo-spica*. It is never a very satisfactory subject, and is hardly worth growing. The white patches are really evidence of ill-health, although the condition has been perpetuated by propagation. Such patches frequently die and give the plant a very shabby appearance. Nothing can be done to counteract the ill-effect of the white patches.

SHRUBS FOR BANK (*F. J. Jackson*).—There are several shrubs which could be used for clothing the bank beneath your window. The hardier Heaths could be used with advantage, especially *Erica mediterranea* hybrid. It grows 12 inches to 18 inches high, and spreads rapidly. The flowering-time extends from December to May. *Hypericum calycinum*, 12 inches high, forms a dense carpet of evergreen leaves, and flowers freely during the summer. It should be cut to the ground-line each March. The flowers are yellow and 2½ inches to 3 inches across. *Cotoneaster microphylla* is a spreading evergreen bush 12 inches to 18 inches high, which bears white flowers in May and red fruits in the autumn. *Cotoneaster horizontalis*, 1½ feet to 2 feet high, is deciduous, and is most attractive in the autumn when bearing scarlet fruits and red and orange foliage. Common Ivy would also make a good evergreen covering, but, of course, there would be no flowers. Sun Roses or *Helianthemum* in variety would also be successful. They bloom freely during May and June. Whichever of these plants is chosen, it should be used alone rather than in mixture. If the existing shrubs are attractive kinds, there is no reason for their removal, as any of the subjects recommended would work in well with them.

LILACS FROM CUTTINGS (*Lil. Ak, Aber*).—You will find that Lilacs are not very easily or quickly raised from cuttings. Cuttings can, however, be rooted both in the summer and winter. In the former case, short, half-ripe shoots 4 inches to 6 inches long are taken in July or early August, and are inserted in pots of light soil in a close propagating-case. In the other instance, cuttings 12 inches long are made of fully ripened wood as soon as the leaves fall in the autumn. They are planted in a sheltered border out of doors, covering all except the upper 3 inches of each cutting in the soil and making the soil about them quite firm. But an easier method of propagation is to layer the lower branches into light soil during February or March. These will take root during the summer and form plants more quickly than others raised from cuttings. The Lilac is not a very suitable shrub for planting in the way you describe to form a covered walk. It is inclined to grow very densely from the bottom, and the effect would be rather stiff unless you dispense with training and allow the plants to grow naturally, thus simply lining the walk with bushes. The common Lime is often used for covering walks in the way you describe, but Beech, Hornbeam and Hazel are also chosen. It is not usual to plant a border between the bushes or trees of a pleached walk and the path. If anything is used, however, it should be some spring-flowering bulb or something that will withstand considerable drought and shade.

THE GREENHOUSE.

CULTIVATION OF GERBERAS (*G. H.*).—When Gerberas are raised from seeds, they are very liable to go off during their earlier stages; but, once they become established, little trouble is then experienced in this respect. The main roots of the Gerberas are of a deep descending nature, with comparatively few fibres, for which reason they grow more freely when planted out in a sheltered border—as in the front of the Orchid-house at Kew—than they do in pots. Your plants are certainly flowering very early, which would seem to indicate that they have been kept warmer than they really require. The greatest measure of success under pot culture is attained when the plants are kept during the winter in a structure where a temperature of 45° to 55° is maintained. At that season overwatering must be strictly guarded against. Under these conditions the plants will partially rest. Then, on the return of spring, any that need it should be repotted in a mixture of loam, leaf-mould and sand. With a natural increase in temperature and in the supply of water, the plants will soon grow and in time flower. Good examples may be grown in pots 5 inches in diameter. Throughout the summer they may be grown in a greenhouse without any artificial heat, or in a frame. While they may be shaded during the hottest part of the day, exposure to a fair amount of sunshine is very necessary to their well-doing. When the pots are furnished with roots, an occasional stimulant during the growing season will be helpful. On the approach of autumn frosts they must be taken into the greenhouse.

In the case of your plants that are now flowering, we advise you, as soon as the blossoms are over, to cut off the old flower-spikes and repot the plants in a compost as before advised. In repotting, as much of the old soil should be taken away as can be done without unduly distressing the roots. Will you please send us a diseased portion of one of your *Amaryllids*?

MISCELLANEOUS.

VARIOUS QUESTIONS (*L. B. W.*).—The names York and Lancaster belong to one Rose. It could be obtained from Messrs. H. Merryweather and Sons, Southwell Notts, or Messrs. Alex. Dickson and Sons, Newtownards County Down, Ireland. *Rosa Mundi* is sometimes erroneously termed York and Lancaster. The names York and Lancaster are without botanical significance, and apply to an individual variety in the same way as *La France* and *Gloire de Dijon* apply to other well-known garden Roses. *Rosa* is the generic name of the Rose family, but it is not used for varieties which have been raised artificially in our gardens, and applies to the wild species only. The *Hen and Chickens Daisy* is botanically known as *Bellis perennis prolifera*, and is so called because of the nature of its flowering, small flower-heads issuing from and encircling the larger central flower-head. The variety is more curious than beautiful. Try Messrs. Barr and Sons, King Street, Covent Garden, London, W.C., for either plants or seeds. Seeds of the *Digitalis* you mention can be obtained from Messrs. Pennell and Sons, Lincoln.

WEEDS ON LAWN (*Constant*).—If you allow the grass on your lawn to grow to a height of 6 inches or 8 inches before being cut, you will encourage the weeds to produce and shed seeds, thereby spreading instead of destroying the weeds. It is advisable to hand-weed as far as possible; then give a sowing of lawn sand.

NAMES OF PLANTS.—(*T. T.*).—*Leucojum vernum*, the Spring Snowflake.—*Greyhound*.—*Herniaria glabra*.—*T. P.*—1, *Pinus insignis*; 2, *Quercus Ilex* (Evergreen Oak). The Blackthorn may be successfully used as a hedge.

THE EDITOR'S TABLE.

An Interesting Hyacinth.—Messrs. Barr and Sons of King Street, Covent Garden, London, W.C., send us a plant of Hyacinth Lady Derby. The bulb had been specially treated so as to induce it to form a number of flower-spikes, which are infinitely more graceful than the large, massive spikes obtained from untreated bulbs. Messrs. Barr write: "We have much pleasure in sending you a pot of the many-flowered Hyacinth Lady Derby. These many-flowered Hyacinths are, of course, as yet a novelty in this country, the numerous elegantly set spikes being produced by means of special treatment of the bulbs in their younger state. These Hyacinths can now be had in five distinct colours, and, the price of the bulbs being quite moderate, they are within the reach of all. As you will see, the pot contains only the one bulb, from which six spikes have been thrown."

SOCIETIES.

DUMFRIES AND GALLOWAY GARDENERS' ASSOCIATION.

THE usual fortnightly meeting of the above association was held in the Wesley Hall, Dumfries, on the evening of March 6, Mr. S. Arnott (chairman) presiding. A short discussion arose on the subject of the best herbaceous plants for early August bloom—a question held over from the last meeting—and some useful information was given. Mr. J. B. Crichton, Kirmount Gardens, in response to a request, gave some further useful information respecting his method of cultivating Potatoes in the open for use in February. The chairman then called upon Mr. Esson, Drumlanrig Castle Gardens, to give his paper on "Present-day Gardening." This interesting and extensive subject Mr. Esson dealt with very fully and ably. He pointed out the difference between gardening in former and in present times, and emphasised the varied requirements of the gardens of to-day. He discussed the large garden, or rather gardens, which afforded scope for much diversity, and spoke of bedding-out, herbaceous borders, the Rose garden, the wild garden, the shrubbery and the rock garden, giving many hints as to the best practice in these different branches. Mr. Esson then dealt with smaller gardens, strongly expressing his views in favour of individuality, and deploring the sameness shown by so many small gardens. An interesting discussion took place, during the course of which Mr. Esson was complimented on his excellent paper. On the motion of the chairman, he was heartily thanked.

THE GARDEN.

No. 2262.—VOL. LXXIX.

MARCH 27, 1915.

NOTES OF THE WEEK.

The Mezereon.—The free-flowering qualities of the old and well-known shrub *Daphne Mezereum* warrant it a place in every garden, for it is suitable for those of large and small area, some of the finest specimens being met with in cottage gardens. Cottagers in South Lancashire appear to be very fond of it, for fine examples are often seen in their gardens, possibly by reason of its being so easily moved from garden to garden by means of seeds or tiny plants, and after it has once been planted being left severely alone. It is one of those plants that rejoices in cool, moist soil, and usually gives the best results when sheltered from very hot sun. Several varieties are supplied by nurserymen in addition to the ordinary red-flowered kind. The two best are *grandiflorum*, a tree-flowering variety with red flowers, which open during December and January; and *album*, a white-flowered form which blooms during February or March. The former, like the latter, produces rich red berries in June, and the latter bears yellow berries.

Two Beautiful Early Flowering Trees.—How beautiful *Cornus Mas* and *Parrotia persica* are just now with their masses of blooms! The other day we saw a large bowl with some cut sprays of them mixed with sprays of *Alexandrian Laurel* (*Danæa*

aurus). The bright yellow flowers of the Cornelian Cherry made a pleasing contrast to the Parrotia, with its conspicuous rich red stamens, while the graceful sprays of *Danæa* added just the finish required.

A Charming Golden Shrub.—Few evergreen shrubs are as bright and attractive as *Cassinia ulvida*. It is a low-growing, branching bush, covered with tiny leaves, which are powdered on their under surface, so that the bush has a golden hue at all seasons. The flowers are very small, but borne in large clusters terminating the shoots.

It is a good subject for a dry, warm bank, and in such a position the colouring is most attractive, especially just now, as the young growth is pushing forth. It is a native of New Zealand and sometimes listed under the name of *Diplopappus chrysophylla*.

The Chinese Davidia.—On the plant of *Davidia involucrata* *Vilmorinii* in the Himalayan House at Kew two fruits are approaching maturity. We believe this is the first time a tree has borne fruits in this country. They

from 1904 until the present time has continued to produce new fronds, and appears to be in a perfectly healthy condition. Copies of the *Gazette*, containing full particulars of this interesting experiment, can be obtained from Mr. Druery, 11, Shaa Road, Acton, London, W.

Forget-me-not Day in London.—We understand that a movement is on foot to sell sprays of Forget-me-not in London on May 1 in aid of disabled sailors and soldiers. We are

pleased to note that it is the intention of the originators of the scheme to sell, as far as possible, natural flowers, as by so doing those whose business it is to grow cut flowers will be assisted, as well as those who have been broken in war. After all, artificial flowers at their best are but caricatures of those culled from Nature.

The Dahlia Year Book.—The committee of the National Dahlia Society is to be congratulated on publishing its Year Book during the present crisis. The many interesting and instructive articles that it contains should prove of considerable interest and assistance to those who, more or less successfully, attempt to grow these autumn flowers. Mr. C. Harman Payne gives some very interesting particulars

FLOWERING SHOOT OF *DAVIDIA INVOLUCRATA*. A TREE IS FRUITING IN THE TEMPERATE HOUSE AT KEW.

are solitary, about the size and shape of a Walnut, green, with a glaucous bloom, and slightly grooved. Each fruit contains only one nut.

Ferns in Air-Tight Bottles.—In the March issue of the *British Fern Gazette* the editor, Mr. C. T. Druery, gives some interesting particulars of a Hart's-tongue Fern that he has had in a hermetically sealed glass pickle jar for ten years. Originally placed in the jar, with a little wet, washed sand in the bottom, when a minute plant bearing a solitary, tiny frond, the plant in the course of a year or two reached the stopper, and

on the evolution of the Dahlia as a show flower, and park superintendents and gardeners generally would do well to study Mr. Cheal's remarks concerning the Dahlia as a decorative plant for parks and gardens. The Year Book is splendidly printed and bound, but some of the portraits of Dahlia enthusiasts might have been of a more recent date. The hon. secretary of the National Dahlia Society is Mr. J. B. Riding, Forest Side, Chingford, London, from whom, we presume, copies of the Year Book can be obtained.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Trees for Screens.—In the interesting article on this subject in your issue for March 6, page 119, certain shrubs were mentioned for growing under large trees. I should like to add to these *Abies nordmanniana*. Since I saw this some years ago growing in dense woods at Les Barres, I have planted it in similar situations, and with great success. For those to whom *Aucubas* are as red rags to bulls, I recommend the restful green of Nordmann's Fir.—E. A. BUNYARD.

Saxifraga lilacina.—One of the most striking and most beautiful Saxifrages in flower at the present time is *Saxifraga lilacina*. When yards away from this minute gem, one finds one's self hurrying towards it to examine at close range its large, lilac purple flowers, which are borne in great profusion on hairy stems half an inch to an inch high. To further enhance the effect, the petals are reflexed, and show off to great advantage the gold-tipped purple stamens. Of creeping habit, *S. lilacina* has very minute, lime-tipped leaves, produced closely together, giving the plant the appearance of little mats of silvery grey. It is a native of the Himalayas, and is thriving here in a gritty compost.—JOHN G. BROADHEAD, Wooldale, Thongs Bridge, Huddersfield.

Home-Grown Vegetables and Our Food Supply.—Referring to your kind enquiry of February 11, I have placed the matter before the committee of this society, and, after fully considering the matter, they were unanimously of the opinion that we ought to do all in our power to further your praiseworthy efforts. The steps we have decided to take to this end are as follow: To issue a circular-letter to all the members of the society and to the residents in the neighbourhood pointing out the necessity of cultivating as many vegetables as possible this year, and inviting any who would like to cultivate a small plot of land to send their names in to me with a view to our endeavouring to secure some of the land lying idle in this neighbourhood for their benefit. As it would be impossible for me to embody the whole of the different aspects of the case, in my opinion, in a circular-letter, I have ventured to write them out more fully with a view to insertion in our local paper; but a member of our committee, to whom I have shown the accompanying article, suggested that it would be productive of more good if inserted in a paper like THE GARDEN, and for this reason I forward it to you.—ERNEST C. CROSS, Hon. Secretary, Hale End Horticultural Society. [The article referred to by Mr. Cross appears on page 155.—ED.]

— I am pleased to say that we have decided to continue our society during the present year, as the importance of such work is very necessary at the present time in stimulating interest among all cultivators of the soil to bring every available plot into use. It may be necessary to curtail expense on the present occasion, but this should be everyone's aim in such a great national crisis.

You will be pleased to hear that your article greatly helped to influence the foregoing decision.—J. L. WRIGHT, Hon. Secretary, Wharfedale Silkestone Floral and Horticultural Society.

Undesirables in the Rock Garden.—"E. H. J." has rendered a great service in calling your readers' attention to undesirable plants for the rock garden, as it is quite as necessary for beginners to know what not to plant as to know what to make a start with. I cordially agree with his list, the worst of which I have found to be *Euphorbia Cyparissias*. Being smitten with the pretty appearance of this plant, I introduced it in my alpine garden, and I have regretted it ever since, as do what I will I have so far been unable to eradicate the wretch. A few years since, while walking along a road near Termignon (in the

A HOME-MADE RUSTIC HURDLE. THESE ARE VERY USEFUL FOR WIND SCREENS.

company of a well-known and greatly respected horticulturist), we espied, a little way off, a patch of glorious blue, which on closer approach we found to be *Ajuga genevensis*. Attracted by its brilliant colour, I dug up some of it, and in due course installed it with pride here. I lived in joyous expectation of seeing it flower the next year. It did so, but what a falling off was there! It came a dingy, dowdy blue; but great as was that disappointment, it was nothing to what was to follow. The fiend began to run underground, and soon appeared yards away from where I had planted it, so that I had to lift rocks which it had undermined. Times out of number I had to dig up pieces of it, so, fellow rock gardeners, beware of this siren. "E. T. E." sings the praises of *Cerastium tomentosum*, a plant which

is out of place in a garden of choice alpinists, which all true alpinists seek to grow. Fancy cutting alpine plants back twice a year as though they were some subject in a topiary garden! "E. T. E." condemns himself. The proper province of *Cerastium tomentosum* is that of an edging plant in borders, and even then it needs close watching. It surprises me to see Mr. G. R. Phipps writing that "in some rock gardens where there are spaces beneath the trees which have to be covered," &c. Without desiring to claim great knowledge, I have understood hitherto that no rock garden should be even near a tree, much less have one in it. What about drip, which is fatal to alpinists and injurious even to plants in borders; and what about the roots of trees, not to mention shade? Some people must have curious ideas about rock gardens. They surely have never seen the Alps, nor have read books on the construction of rock gardens. May I refer your correspondent to page 1 of "The Small Rock Garden," published by Country Life, Limited, and the illustration facing the title page? No trees there! With me *Zauschneria californica*, planted in full sun, is far from a ramper; but is this an alpine? Mr. William Robinson rightly describes it as a perennial, meaning a border plant, which it really is. Arabises, Aubrietias and *Helianthemums* are not an unmixed blessing in an alpine garden by reason of their rampageousness. As one cannot well do without them, I am treating them as unfavoured pictures at the Royal Academy are treated, viz., skying them. Raised feet above their smaller brethren, they in their season produce glorious cascades of colour.—ALPINIST. [The sentence in "The Small Rock Garden," by Mr. E. H. Jenkins, referred to by "Alpinist," is as follows: "The best position for a rock garden is one entirely in the open, a position removed from the presence or near proximity of large trees, equally prejudicial to success by reason of their rootspread and the shade or drip consequent upon their overhanging branches."—ED.]

Wattle Hurdles for Shelter.—The illustration represents a form of wattle hurdle most useful for protecting shrub and tender plants from cold winds, especially in early spring. These hurdles are largely used by the seaside, where north and easterly winds have a deterrent effect upon the growth of so many plants and evergreens. This is an industry I have started on this estate, employing much labour in the woods in cutting down and converting the underwood, which grows so freely in this part of Hampshire, into hurdles. Hazel is the principal wood from which the hurdles are made, although Ash, Maple and wild Cherry are also used. The hurdles are 6 feet long, 3 feet high and closely woven. The "rods," as they are termed, are split, and thus made more pliable. They are easily wound around the end, although it is a knack belonging to the experts at the work, which requires considerable practice. In some parts the hurdles are used for road-making across swamps and building up the banks of water-courses. I find them especially valuable for many uses on an estate.—E. MOLYNEUX, Swanmore, Hants.

Narcissus pallidus præcox.—My attention was attracted by a note on this early Pyrenean Daffodil in your issue of March 13. A long bank of it here is now a perfect picture. Last year the first flowers opened at the end of January. This year they were exactly a month later. You mention that it is a difficult plant to increase, and that in some places it actually deteriorates. But in an experience of pallidus præcox extending over fifteen years, I must confess to having found it one of the most prolific plants of its kind in my garden. It must be understood that I am speaking of its increase from seeds, not from offsets. Among the species and varieties of the Narcissus grown here (and there are some hundreds of them) pallidus præcox is the most plentiful and the most consistent seeder of all. It is growing here on a rough hedge bank, and up till two years ago I allowed it to ripen and shed its seeds *in situ*. For the last two seasons I have taken pains to watch and gather the pods, and the seeds have been sown outdoors in rows in little nursery beds. As a result I have now many thousands of healthy seedlings. It has been well worth the trouble, for in a year or two I ought to have a fine quantity of good flowering bulbs of what is now, I understand, becoming an increasingly scarce plant.—ORNATUS, Rye.

Daffodil or Narcissus?—The section to which the name of Daffodil with its variants was applied was the one to which the Primrose Peerless and Poet's Narcissus belong. Lyte thought these and the Pseudo were distinct genera, and remarks that this was called "Pseudo-narcissus because his flowers are somewhat like to Narcissus: in English, Crowbels." Gerard calls the first "Narcisse"—a very good name too—in a translation from Theocritus:

"But when the Girls were come into
The medowes flouring all in sight,
That Wench with these, this Wench with those
Trim floures, themselves did all delight:
She with the Narcisse good in sent,
And she with Hyacinthes content."

"Daffodilly," "Daffodowndilly" and "Primerose Peerlesse" are other of Gerard's names. "Laus Deo" is in Tusser's list of plants for this, and we know from Turner's "Libellus" that this was a common name in Essex for this flower. "Cencliffe" is a very old name for the Pseudo or Bastard Daffodil, and besides these there are also a large number of local names applied to both and to particular species, e.g., "Sweet Nancy" to the late double white. It may be permissible to make a note here of Mistletoe being used in churches at Christmastide, which the Rev. J. Jacob, in quoting lines from Gay's "Trivia," seems doubtful about. But an old custom at York was that of decking the altar of the Cathedral on Christmas Eve with Mistletoe, and I have read somewhere that it was customary to employ Mistletoe in churches for the same purpose as in private houses.—R. P. BROTHERSTON.

What is a Daffodil?—What is a Narcissus? What is a Daffodil? are questions asked and answered by the Rev. J. Jacob in THE GARDEN of March 6. The names are absolutely convertible, Mr. Jacob thinks. John Dicks called them all Narcissus in 1771, and "so it has continued up to the present time." But is it not a curious thing that, if the matter is as simple as Mr. Jacob supposes, there should have been up to the present time a more or less general belief among Daffodil-mongers, as well as among the profane, that a Narcissus

is not necessarily a Daffodil? Language is a freakish old person; but there is one thing in which she is notoriously consistent, and that is her regard for economy. None of her words has a sinecure. If they do not work, neither shall they live. If I know anything of Language and her ways, I should say it is extremely unlikely that she has allowed two words to discharge exactly the same functions from the time of Charles I. till now. I really think Mr. Jacob must reconsider this matter, and allow due weight to current usage. Perhaps I may be allowed to state what I have always understood to be the ground covered by the two words. Unfortunately, not being near a reference library, I cannot quote authorities; but I have been a good deal occupied with the Narcissus and its literature all my life, and therefore venture to state what I have always supposed to be the scope of the words. "Narcissus," I take it, then, is the generic word, and covers the whole tribe, regardless of form. "Daffodil," on the other hand, was a name in general use for certain yellow forms of Narcissus which were common in Old English gardens, viz., the Lent Lily (N. Pseudonarcissus), the Peerless Narcissus (N. incomparabilis), single and double, and the Hoop Petticoat (Corbularia). The Polyanthus Narcissus (Tazetta) was not (and possibly still is not) a common flower of English gardens, but rather a Dutch florist's flower. The Narcissus by pre-eminence was that which was believed, with or without sufficient grounds, to be the Narcissus of the Greek and Latin poets—the Narcissus poetarum (less correctly "Narcissus Poeticus"). The Jonquil (or Rush-kin) is another form of Narcissus, which I can hardly think an English cottager of a previous generation would have dreamed of calling "Daffodil." N. Poeticus recurvus, the form of Poeticus which was probably most plentiful in the old gardens, he might style "Narcissus," though I doubt it, Narcissus being rather the comprehensive term used by those who have written about these flowers; he would probably speak of it as the "Pheasant's-eye," and a very good name too. After all, in the matter of English plant names the cottager is an authority not to be despised; and I should think he would be just as likely, or as little likely, to speak of a Jonquil or Pheasant's-eye as a Daffodil as he would be to call a China Aster a Michaelmas Daisy. To sum up, may I ask Mr. Jacob whether it is now permitted to call a Pheasant's-eye Narcissus a "Poetic Daffodil"? To be forewarned will obviate the danger of shock. It has just occurred to me to consult the only authority that is accessible to me on this point, viz., Webster's International Dictionary, and this is what I find: "Daffodil—a plant of the genus Narcissus (N. Pseudonarcissus). It has a bulbous root and beautiful flowers, usually of a yellow hue." I had something to say also on the subject of alternative names for Daffodils and other Narcissi, but that must keep for another time.—SOMERSET.

FORTHCOMING EVENT.

March 29.—At Rawdon, near Leeds, in the Conservative Club, in aid of local Red Cross work, Mrs. Duggan of Clevedon, Altrincham, will lecture on "Bulbous Plants for the Garden, with Special Reference to Daffodils and Lilies." Lantern slides and a collection of cut Daffodil blooms in variety will be shown. Mrs. Duggan will be glad to repeat this lecture elsewhere in aid of any of the war charities.

COLOUR CHARTS: WHAT IS WANTED.

THE interesting article by the Rev. Joseph Jacob in THE GARDEN of March 6 again opens up the question of a proper, definite and much-needed standardisation of colours applicable to floral descriptions. I am afraid, however, none of his suggestions is likely to achieve much more satisfactory conditions than obtain already.

Mr. Jacob begins by criticising the descriptions given in nurserymen's catalogues, and although he realises some of the difficulties in the way of the compiler of catalogues, I do not think he has quite grasped them all. In the first place, if a nurseryman takes any one of the publications mentioned and bases his descriptions thereon, how can he be sure that the reader of such descriptions will possess that particular "répertoire" or "chart" or "code"? Why, even the Royal Horticultural Society has been unable to remain true to its first love. A year or two ago, having acquired a certain number of copies of the "Répertoire de Couleurs," it urged upon its members and the general public the multiple advantages of possessing such a standard, and I think, also, upon the horticultural trades the desirability of using it in their descriptions. It now appears that, having distributed a certain number, it has abandoned it for its own use in favour of Ridgway's Chart. I do not know Ridgway's Chart yet, but I suspect that when I do get it and endeavour to compare certain shades with what should be their equivalents in the "Répertoire," there will be very decided differences, because I am confident that the individual perception of colours varies to a far greater extent than is generally supposed. I have personally tested this by giving flowers of exactly similar shades (self colours) to different individuals and asking them to match the colours. On one occasion this was done with Carnation Uriah Pike, all carefully selected blooms. Five people each produced what they considered was a match, and each produced a different shade; moreover, although all agreed that the five shades were different, each maintained that his own selection was right. I cannot explain this, but only state it as an interesting instance of the difficulties the descriptionist has to overcome.

But there is another and greater difficulty still. Certain colours in flowers vary many shades in different lights. This is particularly applicable to the most difficult of all divisions to describe—the shades of blue, purple, lilac, lavender, and mauve, such, for instance, as occur in Irises and Delphiniums. If Mr. Jacob wants a really thrilling experience, he should spend one bright sunny afternoon among Japanese Irises as they grow here, and make careful notes as to their colours according to the "Chart." Then let him go over the same ground the next morning if it is dull and prepare independent descriptive notes. I think he would be surprised to find how much more the flowers vary than the "Chart" does, and unless he is blessed with exceptionally good colour vision, I think his descriptions on the two days would vary in nearly every case. I doubt if anyone would be able to fix the shade usually described as violet purple three days in succession to the same example in any chart yet published. Brilliant sunshine adds a luminosity to such examples that does more than change the shade

it makes one hesitate as to whether to approach it through the reds or blues to find its exact match in the colour chart. Try the same colour tone or shade on the next day when the light is grey, through being overclouded, and again on a bright, clear morning early, and the result will be very different.

Again, Mr. Jacob has, like the rest of us, undoubtedly noticed the brilliant intensity of colouring acquired by certain plants flowering in Scottish gardens in September as compared with the same things flowering in the South a week or two earlier; and at the Royal Horticultural Society's shows he must have noticed that certain Phloxes, for instance, vary many tones in colour, according to the district in which they have been grown. How is it possible, then, for any uniformity of description to become prevalent unless with the same chart, under the same conditions, the same authority decides upon it?—which, obviously, takes the responsibility out of the hands of the compiler of catalogues, because if six growers each cultivated the Tulip Siren that Mr. Jacob speaks of, even using the same colour chart, I think it would be found that their descriptions would differ considerably as to "exactly the shade of rose."

There is another minor difficulty. Colour-printing has not yet attained that perfection that it is permanent. In the "Répertoire" I have before me as I write, some of the blues are already taking on a sickly green tint, and on some sheets it will soon be impossible to distinguish No. 1 from No. 4.

I am well aware that Mr. Jacob did not set out to find more difficulties, but a method of overcoming those he had discovered, which is not so easy. First, as regards the "Chart." He does not say so, but I read into his paragraph on the "Répertoire" the words "stupendous and unwieldy," and it is, for ordinary everyday use in the garden. However, I think so far it is the most *complete* attempt at standardisation made, and if any degree of accuracy is to be achieved, it appears to me to form the best standard *work of reference* in existence. The number of variations is immense, but inasmuch as in most instances a floral example has been given of each, it would not seem to be too many. Indeed, my own experience has been that there are still certain tones that have no place therein. But how is it to be applied? Every Rose catalogue, hardy plant catalogue and bulb list published badly require revision. Not one of them has been the production of individual effort on the part of any one person. Messrs. So-and-so introduce a new Tulip. When it is put in commerce, it is described in their catalogue according to what their compiler conceives to be a correct standard of colour (usually his own). Other firms buy stock and eventually catalogue the same variety, adopting

the original description with the stock they purchase, right or wrong. The result is that the same shade of colour gets half a dozen different names in the same catalogue. I am not sure that if everyone gave their *own* opinion on the matter of the colour of a novelty, things would be much better.

What, then, is the remedy? Of one thing I am sure. If it is left to the horticultural trades, unaided, to bring about the revolution, it will never be done. Take the general catalogues issued by any firm, and think what it would mean to revise all the descriptions therein. Start

THE NEW NARCISSUS CYCLAMINEUS HYBRID SHOWN BY MESSRS. BARR AT VINCENT SQUARE LAST WEEK. (See Mr. Jacob's notes.)

now with the Crocuses and go on with the Tulips, Irises, Roses and all the etceteras throughout the coming year. Even supposing some firm could be found who were willing to incur the expense, or could afford it, of bringing every description possible within the understanding of the possessor of the "Répertoire," would such production be accepted as authoritative?—quite apart from the fact that it is hardly likely that any commercial organisation would be content to provide such a catalogue with a view to its being generally copied.

GEORGE DILLISTONE,

(To be continued.)

DAFFODIL NOTES.

BY THE REV. JOSEPH JACOB.

The Midland Daffodil Society.—As the dates (April 21 and 22) which have been fixed for this show approach, it may be well to say that a plebiscite of members was taken some time ago, when it was found that a good majority of votes had been recorded in favour of holding it as usual. The committee accordingly decided to go on with it as arranged. I take this opportunity of asking all who are in a position to do so to accord it all the support they can, either as exhibitors or subscribers, or both. It seems to me that one most important reason which can now be urged for its non-abandonment is the lateness of the season. To cover any loss and the possible wiping out of the small balance, one member wrote to the treasurer offering a special subscription of five pounds if five more would give the same. I believe that up to the present two promises in addition to the original tentative one have been received, leaving three more to be made.

Royal Horticultural Society's Classified List of Names.

—A long discussion took place at the Royal Horticultural Society's Narcissus committee meeting on March 9 relative to the large and increasing number of names sent in for registration. The general opinion seemed to be that it would be well if something could be done to limit the huge output. Messrs. P. R. Barr, G. W. Leak and myself were appointed a sub-committee to try to suggest some workable way out of the difficulty. When we have consulted together and reported to the general committee, I will refer to the subject again. The whole of the difficulty arises from the undue haste of raisers to name their seedlings before they really know if they are ever likely to appear on the public stage. A little restraint in this matter would help very materially to overcome the difficulty. Until a variety has lived for a certain time, and unless it is found to have merits as either a garden

plant or a show flower, it might well be allowed to remain "incog." under a number, or, if more convenient, have a sort of pet or garden name assigned to it for home use only.

Daffodils at Vincent Square on March 16.

—There were but two orthodox groups of cut blooms, and a few bowls with fibre-grown plants in a third, on this date. If we add a few stray pans of cyclamineus and minimus scattered up and down the various groups, and the Queen of Spains, Alice Knights, corbularias and two or three others in the beautiful spring border like arrangement of Messrs. Barr and Sons, we have enumerated

the whole of those that were there. Alice Knights (D, 3½; S, 1½ x 1; C, 1½ x 1½) received an award of merit for growing in pots. It is free flowering, early, not too tall and tractable. By this I mean it allows itself to be gently forced with a good grace, and does not look as if it always fought against it.

Messrs. J. R. Pearson and Sons staged in a light and tasteful manner an excellent collection of pot-grown flowers. Its chief value consisted in its affirmation of the suitability of certain varieties for pot work. It sounded a little strange to hear one lady casually remarking to another, "There is nothing much better than the *old Firebrand*." To one who remembers the avalanche of Leeds and Backhouse seedlings poured forth by Peter Barr in the days of yore, "old" sounds incongruous at first when joined adjectively to *Firebrand*, but on second thoughts it tells us of the march of Time. *Firebrand* is growing old, but it is crystallising out as one of our best pot plants. I have always maintained that as far as my own experience goes, *Homer* is about the best of all the Poets for the same purpose. Mr. Duncan Pearson and his foreman confirmed my opinion at this show, both verbally and visually. *Weardale Perfection* and *Blackwell*, as one would expect, were good. I was again struck with *van Waveren's Giant*. Readers may remember that I mentioned there was a fine vase of it on Mr. Bourne's stand at the Forced Bulb Show. Judging by the lists in the 1913 and 1914 Year Books, it does not seem to be known as suitable for pots, but from present appearances it looks as if it was. I thought both *Florence Pearson* and *Mrs. H. J. Veitch* distinctly good.

Messrs. Barr and Sons had a rather mixed group. A very lovely cyclamineus hybrid stood out by itself. The long, refined trumpet was just matched by the graceful, narrow, reflexing perianth segments, the whole bloom being a rich uniform yellow of about the shade of *Autocrat* (see illustration). It is very unfortunate so few of this charming type of hybrids live for any length of time. I append its measurements: D, 3; S, ½ x 1⅜; C, 1½ x 1. The only other named flower that caught my eye was a massive deep golden yellow *Ajax* with a slightly elliptical perianth and a widely flanged trumpet. It was called *Golden Chief*. Measurements: D, 4½; S, 1¼ x 1¾; C, 1¾ x 2¼.

Descriptive Terms.—From one or two communications that I have received, I think a good many people besides myself would welcome a recognised nomenclature. There should be one or two words to describe the texture of the perianth.

For example, what a contrast there is between that of *Autocrat* and *Michael* on the one hand and that of *Croesus* on the other! I think I once heard Mr. Crosfield describe the latter as "flannelly," which is not at all a bad word to use for that coarse, woolly-looking texture.

A FRAGRANT WHITE ROSE.

ALTHOUGH *Rose Mme. Alfred Carrière* was first put into commerce so long ago as 1879, it is still a great favourite with all who appreciate varieties with good and pronounced fragrance. It is classed by the National Rose Society as a Hybrid Noisette, and is best grown as a large, free bush, as shown in the accompanying illustration. Treated in this way it blooms profusely, and, unlike most other rambling Roses, gives a good second display in the autumn. Newly planted bushes do not, as a rule, flower freely, but when

BRITISH ROSES OF RECENT INTRODUCTION.

MANY new Roses of great attractiveness have recently been introduced by British rosarians. Conspicuous among these in any comprehensive collection are such fine specimens of the Hybrid Tea as *Josephine* and *Majestic*, from the world-famous nurseries at Waltham Cross in Hertfordshire, of which the former has, to my mind, distinct reminiscences of the venerable (and invincible) *Gloire de Dijon*; while the latter somewhat reminds me of my own English namesake, which was also raised by Messrs. William Paul and Sons, and is, I should imagine, like its gracious predecessor, a very fragrant Rose.

Several Hybrid Teas of the greatest distinction come to us from that highly distinguished raiser,

ROSE MME. ALFRED CARRIERE, AN OLD BUT FRAGRANT WHITE VARIETY.

the bushes are thoroughly established and not overpruned, they give a very good account of themselves. Practically all the pruning that is necessary is thinning out of old or obviously weak wood and the removal of soft tips. Although best grown as a large rambling bush, it is a good white Rose for arches, pillars or pergolas, and the large blooms are excellent for cutting. I have also found that *Gustave Regis* gives much better results when grown in this way, although I make a point of pruning it rather harder than I do *Mme. Alfred Carrière*. There is no doubt that many of these vigorous Roses give far the best results when allowed to grow almost as they like, *Grüss an Teplitz* and *Irish Elegance* being others that occur to one.

B. M.

Mr. Hugh Dickson of Belmont, near Belfast, two of the grandest of which are *Lady Clanwilliam*, whose uniquely exquisite attributes I have already in *THE GARDEN* endeavoured to emphasise, and *Mrs. James Lynas*, of luminous aspect and almost absolutely faultless formation.

Brilliant, whose complexion sufficiently illustrates the significance of its name; *William Cooper* and *Mrs. Archie Gray* are others, each of which may be said, without any exaggeration, to have eminently distinguishing beauties and characteristics of its own.

Chief among the most recent creations of Mr. Samuel McGredy, the redoubtable rosarian of Portadown in Ireland (who has given us so much that is of permanent value), are *Edgar M. Burnett*,

a variety of superb endowments, generally regarded as an improvement on Lady Alice Stanley; Colleen, a charming rose pink acquisition, with a high-pointed centre; Florence Forrester, one of the latest and loveliest additions to the great and growing race of Hybrid Teas; Mrs. Ambrose Ricardo, with splendid saffron yellow complexion; and, above all, Iona Herdman.

Of recent introductions from far-famed Newtownards, my supreme favourites are unquestionably H. V. Machin, one of the grandest velvety crimson coloured Roses in existence, which by reason of its greater reliability may possibly supersede the illustrious George Dickson; Killarney Brilliant, which is likely to prove a permanent acquisition; the brilliant Red Letter Day; and Queen Mary, whose truly remarkable combination of rich colours makes the latter fine variety quite

A GARDEN OF ROSES.

MANY of those who strive to keep their gardens gay from spring to autumn must have felt at times a little weary of the increasing attention demanded by ordinary herbaceous beds and borders. To such I suggest a garden of Roses. This proposal would have been ridiculous some fifteen years ago. To-day, thanks to the new class of floriferous Hybrid Teas which combine the good qualities of the Hybrid Perpetuals and Teas, it is possible to have a garden blossoming with Roses from early June to late October, while in mild seasons occasional blooms may be gathered in January. In choosing Roses for display we must select those

lighter shades may be included in such varieties as Betty, Dean Hole, Duchess of Wellington, La Tosca, Lady Pirrie, Pharisæer, Rayon d'Or, Sunburst and White Killarney.

The ground between the Roses may be planted with Violas. These will bloom unceasingly from April until October. Mauve shades are best, as they contrast with and show up the colours of the Roses. Rose beds of one variety only look well on a lawn, which is also an excellent place for standards. Dorothy Perkins and other extra vigorous growers of the wichuraiana class are excellent for arbours and on banks; but for covering walls it is best to select such kinds as the climbing varieties of Caroline Testout, Kaiserin Augusta Victoria, Liberty, Lady Ashtown, La France, Mrs. W. J. Grant, Richmond, with Grüss an Teplitz, L'Idéal and Zephyrine Drouhin, planted

THE STAR-FLOWERED MAGNOLIA (M. STELLATA) PLANTED IN FRONT OF EVERGREENS.

worthy of its exalted name. One of its celebrated contemporaries, viz., Irish Fireflame, is of quite exceptional beauty when in bud form or half blown.

Among other notable introductions of recent origination are Augustus Hartmann, raised by Messrs. B. R. Cant and Sons of Colchester; Cherry Page (for which we are indebted to Mr. Walter Easlea), whose flowers are semi-double and of most vivid carmine pink complexion, with golden yellow suffusion at the base of the petals; Oriflame, a beautiful native of Mr. George Paul's great nurseries at Cheshunt, a decorative variety of splendid floriferousness; and Braiswick Charm, an attractive creation of Mr. Frank Cant, which its eminent raiser regards as the nearest approach hitherto achieved to a perpetual-flowering wichuraiana.

DAVID R. WILLIAMSON.

Kirkmaiden, Wigtownshire, N.B.

kinds which are most perpetual and, among these, those of the most decided colours. Weak colours do not show up well, and should be included sparingly and only for some special reason. The borders should be filled with dwarf kinds. The most striking colour is red, which should predominate. I suggest that at least a third of the dwarfs should be of this colour. Such varieties as Liberty, Richmond, General Macarthur, Laurent Carle, G. C. Waud and Château de Clos Vougeot are suitable. These should be planted 2 feet apart in groups of three to five of one kind, distributed irregularly through the border. The spaces between these can be filled in mainly with groups of bright pink kinds, such as Caroline Testout, Dorothy Page-Roberts, Killarney, Lady Ashtown, Mme. Abel Chatenay, Mrs. W. J. Grant, Corallina, Lady Battersea and Irish Glory. A few

5 feet apart and not within 2½ feet of the dwarfs. These varieties, as well as the more vigorous Gloire de Dijon and William Allen Richardson, are glorious subjects for arches, or as pillar Roses for planting on the lawn or in the shrubbery. Shady parts of the garden may be planted with flowering shrubs and pillars of Gloire de Dijon. H. TEA.

A BEAUTIFUL EARLY FLOWERING MAGNOLIA.

THE Magnolia illustrated above is a good and beautiful kind for nearly all gardens, and one has no hesitation in recommending it to all who appreciate spring flowers. *M. stellata*, as its name implies, has star-shaped, pure white flowers, and is usually the first to open its blossoms, these generally unfolding about the first week in April.

In one respect this is a drawback, as they are liable to get damaged by early morning frosts. However, it is such a beautiful shrub that this risk is well worth taking. Unlike most of the tribe, *Magnolia stellata* never attains a great size, forming at its full development a close spreading bush 6 feet or so high. *Magnolias* appreciate deeply cultivated and well-enriched loamy soil to which some peat and leaf-mould has been added. They can be successfully planted either in September, March or April; but as they are impatient of disturbance, they should be left alone as much as possible. Most nurserymen supply young plants in pots, and these are the best to purchase. The illustration provides an excellent object-lesson in effective planting. It will be seen that the *Magnolia* is situated in front of a dense belt of trees and shrubs. These answer a twofold purpose—they provide shelter from the north and east winds, which mar the flowers in spring, and form a dark background, which emphasises the glistening purity of the blossoms. These are points which ought to be remembered when it is decided to plant and grow *Magnolias*.

W. F.

NOTES ON CATKINS.

THERE is promise of a good crop of Cob Nuts this year. Hazel woods have been bright with golden catkins, and if all goes well, the plantations of Kentish Cobs and Filberts will yield an abundant supply. In the plantations of Kent the Nut trees are all grown in uniform shape. They are basin-like and level topped, and at first sight resemble indifferent examples of topiarian art. It is the result of restricted pruning and thinning, for the best Nuts are grown on the well-ripened, twiggy growths away from the centre of the trees. Let it not for one moment be thought that the showy catkins will themselves be converted into nuts, for they are simply the pollen bearers, and after the golden, dust-like pollen has been distributed by the wind, their work is completed and they fall off. To find the Nut-forming or female catkins, one must look very closely, for they are small, almost microscopic, crimson flowers, invariably produced on well-ripened, twiggy branches. The Constantinople Hazel (*Corylus Columna*) does not appear to be well known; it is a near relative of the Wood Nut, but it will reach a height of 50 feet. The catkins are long and freely borne, and impart quite an attractive feature at this season. The Nuts, which are about the size of Hazel Nuts, are borne in closely packed clusters of six or more, surrounded by curiously twisted husks. Not the least interesting of the catkin-bearing trees is the Alder (*Alnus glutinosus*), which produces both barren and fertile catkins. The former, long and drooping, are usually borne in the autumn, lasting through the winter, while the fertile ones are produced in spring in persistent oval catkins, resembling Fir cones in shape. It is interesting to observe that most catkin-bearing trees depend upon the wind for the distribution of pollen. This applies to the Oak, Birch, Alder, Poplar and Hazel, all producing pendent catkins, from which the powdery pollen is freely carried by the least puff of wind in fine weather. This is one reason why catkins are, as a rule, produced so early in the year, for in the absence of leaves the chances of fertilisation are increased. The Willow or Sallow, unlike the foregoing, does not

produce pendent catkins, neither does it rely upon the wind for the distribution of pollen. Moreover, the catkins are scented, while the crowded stamens and yellow anthers are conspicuous from afar.

C. Q.

COLOURED FREESIAS.

I AM growing a small collection of Van Tubergen's hybrids. I doubt if there are any that are more satisfactory than Contrast and Dainty. Both varieties are tall growers; both have nice-shaped blooms; both are particularly good "doers"; and both are very free, the branched stems bearing several minor sprays which provide

improve on further acquaintance. The plant is too dwarf for the size of its flowers, and the stem is too much on the weak side. Size is nowadays a sort of "charity" among certain appraisers of floral worth, inasmuch as it covers a good many faults. In Robinetta we have a deeper-toned and larger-flowered Tubergenii, almost the rose shade labelled "Spence Red" in the American Colour Chart. Canary is a pretty pale yellow or very deep primrose with orange markings on the lower petals. Like many of these new coloured varieties, it deepens in tone with age. A pretty shade of lavender is to be found in Côte d'Azur, the flowers of which are of good size and freely produced. The plant is not a very tall grower, being only two-thirds the height of either Contrast or Dainty.

SHOOT OF THE CONSTANTINOPLE HAZEL
(*CORYLUS COLUMNATA*).

CATKINS OF THE ASPEN
(*POPULUS TREMULA*).

successional flowers. Contrast is an ivory white with a bright orange blotch on the outermost of its three lower petals; while Dainty, which has much the same open-shaped bloom, is a rosy heliotrope which with age turns to a soft rose. This year I have grown Excelsior, the Freesia that received an award of merit last season. I also saw it exhibited at the Royal Horticultural Society's show on February 16. I am very disappointed with it on this my first introduction, nor does its look give me much hope that it will

Most of this new type are expensive. The lowest priced of those here mentioned is 6s. per dozen. Against this I have proved to my own satisfaction that they are easy to keep and increase, and the purchase of four or six bulbs one season means in two years' time several pots of each.

Mr. Duncan Pearson's excellent advice about cultivation in THE GARDEN for February 20 makes it needless for me to say anything under that head.

JOSEPH JACOB

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Brasso-Cattleya Cliftonii Sir John French (B.-C. digbyano-Mossiae \times C. Trianae).—A variety of handsome proportions and remarkable colouring. The sepals and petals are rosy pink, the shapely lip heavily fringed. Above this the frontal portion is clouded with gold, with crimson

ago by Messrs. Barr at their Surbiton nurseries, has previously been honoured by an award of merit on its good qualities as a flower. On the present occasion the honour was repeated, because of its adaptability to pot culture. Naturally, it is the earliest of the white trumpet sorts, and its ready response to pot cultivation cannot but enhance its value. Exhibited by Messrs. Barr and Sons, Covent Garden, W.C.

THE NEW HYBRID SAXIFRAGA IRVINGII. THE FLOWERS ARE BLUSH PINK.

reticulations at the base of the tube. A rare colour combination in a most fascinating flower. Exhibited by Messrs. Stuart Low and Co., Jarvisbrook, Sussex.

Lycaste Janet Ross (L. rossiana \times L. Skinneri).—A very beautiful and distinct hybrid, exhibited in fine condition. The predominant colour of the sepals and petals is pale primrose, the chrome-tipped lip suffused with crimson and minutely peppered with a similar colour at the base of the tube. A well-flowered example showed the plant to perfection. From Messrs. Sander and Sons, St. Albans.

Saxifraga oppositifolia R. W. Prichard.—Without derogatory intent to the other members of this set, we may well describe this as the most distinct, both in colour and in the form of its flowers. The latter are somewhat starry, petals separated, roundly ovate at first, and finally acutely pointed. The colour is rosy lilac. From Mr. Reginald Prichard, West Moors, Dorset.

Carnation Good Cheer, and, we may add, good colour, pleasing fragrance, vigorous stem and perfect calyx. These are some of the essential attributes that go to make a first-class commercial Carnation to-day, and though we have not yet reached the acme of perfection in the "divine flower," and probably never will, Good Cheer, of roseate hue, is good enough to go on with meanwhile. Under artificial light it is most telling. From Messrs. Wells, Limited, Redhill.

Narcissus Alice Knights.—This supremely beautiful white trumpet Daffodil, raised some years

All the foregoing were shown before the Royal Horticultural Society on the 16th inst., when the awards were made.

Saxifraga \times Irvingii.—This charming hybrid Saxifrage, which obtained an award of merit when shown by Mr. Clarence Elliott at the meeting of the Royal Horticultural Society on February 9 last, is the result of crossing *S. burseriana* variety *macrantha* with *S. Frederici-Augusti*. *S. burseriana* itself is a very variable species, and to those who know only the larger-growing kinds, like *S. b. Gloria*, it would appear that the present plant could hardly have been derived from that species. In the variety *macrantha*, however, we have a form with tufts of very small rosettes of leaves, quite unlike the usually grown kinds, and it was from this that the present hybrid was obtained. The latest form of *S. burseriana* to flower, the variety *macrantha* is not over till the red-flowered *S. Frederici-Augusti* is in bloom, which is not till most of the other forms are over. *S. Irvingii* partakes more of the character of the former, with similar tufts of foliage and single flowers, the only evidence of the red parent being in the colour of the flowers, which is a blush pink, deeper in the centre. The stems are only about one inch or so high, and, as may be seen in the illustration, it is very free flowering. In the same batch of seedlings was another plant which partakes more of the character of *S. Frederici-Augusti* in foliage and habit, but with larger pink flowers, several on each stem. This latter has been named *S. kewensis*.

THE BARDFIELD OXSLIP.

NOW that hardy plants are so extensively grown in all kinds of gardens and situations, it is strange that the beautiful Bardfield Oxslip (*Primula elatior*) should be so universally ignored. It is true that a few nurserymen who make a speciality of hardy plants include it in their catalogue, but, judging by the examples often found shown as this plant, the true form is exceedingly difficult to obtain. This is unfortunate, as it is the most charming member of the Primrose family found growing wild in this country, and will thrive well under cultivation. It has been regarded by some authorities as a hybrid between the common Primrose and the Cowslip, but others regard it as a distinct species and not a hybrid. To those who love hardy plants for their beauty, this will not matter much; it will suffice that the plant has a decided charm of its own. The flowers are pale yellow or primrose in colour, and several, generally from five to eight, will be found surmounting an upright stem some 4 inches to 7 inches high, according to the situation in which the plants are growing. The blossoms assume a pendulous habit and sway about almost like pale golden bells in the spring breezes and sunshine. A single plant will often produce several of these flower-heads, and such an example is of more than usual interest. A curious fact about the Bardfield Oxslip is that it is only found growing in quantity in two localities, viz., the Bardfield district of Essex, whence it derives its popular name, and a district in Cambridgeshire. Isolated groups or specimens are found in a few other counties, but the plant is far from common. It may be of interest to note that in Essex the Oxslip is called by ordinary folk Cowslip, the plant commonly known by that name being known there by the old French name of *Pægle*. In the Essex woods, in the locality named, this beautiful wilding is found by the thousand, the ground beneath the trees in the more open spaces being almost carpeted with the plants. Such a quantity when in bloom in the early spring months provides a picture of great beauty that would lend considerable charm to any wild garden, providing plants sufficient for the purpose could be obtained. The soil in the woods in question is stiff Essex clay, ameliorated by a certain amount of decayed leaves, and those who can obtain plants should aim to give them a cool rooting medium with overhead shade during the hot summer months. There would be no difficulty in securing a large number of plants once a few were obtained, as they stand division well, providing this is done immediately after flowering. The plants also seed freely, and doubtless young plants could be raised from these seeds. In any case the plant is one well worth making an effort to obtain, and it is to be hoped that nurserymen will soon realise its beauty and raise a stock of the true form for sale. It would certainly meet with a good demand.

VEGETABLE MANURE.

AS is well known to many people, stable manure will get rapidly scarcer and scarcer, owing to the increasing number of motors and the remarkably few horse-drawn vehicles. Readers will feel rather "up a tree" to know how to go on, and I beg a little of your valuable space to offer a suggestion. All of your readers have heard of vegetable manure, but many people shy at the name of it, as I pointed out in an article published elsewhere a year ago. But I have always been an advocate of using vegetable manure, or part vegetable and part animal manure, for both flowers and vegetables; and as I know from my own experience what can be done with vegetable manure, I think I am in a position to write to your esteemed paper about it.

The soil here is good but shallow, turning to clay and shale 1 foot from the surface. I find that well-rotted vegetable manure, dug into the borders in the autumn or spring, is productive of good crops of flowers from annuals and perennials. It is not quite so successful with vegetables, seeing that deep digging is also largely needed before big roots of such as Carrots and Parsnips can be obtained. But for flowers on this soil I would just as soon use well-rotted vegetable manure as animal manure, and I wish I had far more of it than I have.

My object in sending you this letter at the present time is to induce readers to think twice before they waste soft vegetable refuse by allowing it to be carted away. The more of this that can be saved from now till next October the better, and then the scarcity of animal manure will not be felt nearly so much. There are, of course, certain ways of going to work, and one of the best is to have a very large pit dug some six feet deep, or rather less, about nine feet wide, and as long as may be convenient. Have this bricked round the sides of the soil, and into this pit throw all the soft refuse that is available. Weeds (provided they are not Dandelions), old Cabbage leaves, long grass, mowings from the lawn, and any of the soft stuff which is taken off the borders throughout the spring and summer, may be thrown into the pit as it is collected. But, of course, keep out stones and such like, as these spoil the manure. It is necessary to have this in an unfrequented place, but this can usually be managed. If the pit is very big, it will, of course, hold a great deal, and should not be disturbed before it is necessary. Lime sprinkled about will help to keep down the unpleasant smell, and after a lot of fresh stuff has been put in, it may be covered with a thin layer of poor soil, which will also help to do this. However, in time it will need digging out, and the rotted stuff should be stacked in an open place—in a field if possible—away from tree roots. Let it remain for a time as it is, or cover it with some soil or manure; and then, after a time, the manure may be removed and the vegetable refuse dug in in the late autumn as manure. In closing, I hope that this suggestion may be of some use to your readers, and apologise for the length of this letter. Very excellent results have been obtained here by using well-rotted vegetable manure for the flower borders, and, seeing manure will be so hard to get, surely vegetable manure might be more generally used instead.

Weekwood, Ecclesall, Sheffield. E. T. ELLIS.

GROWING POTATO TUBERS FROM SEED.

PROPGATION of the Potato from small tubers, and known to gardeners as "sets," is too well known to need description. The fact that this vegetable can be raised from the actual seed of the Potato plant is known to very few.

In common with most amateurs, I have been under the impression that growing Potatoes from seed necessitated the use of a heated structure. However, that this is not the case this article will show. Last year (1914) I obtained a six-penny packet of Potato seed, and sowed it in a pan of sandy soil on March 29. The pan was then placed in a cold frame. It may be remembered that we were favoured last April with some fine, sunny weather, a temperature of 105° being registered more than once in the sun. Perhaps this accounted for my success with cold frame culture, as a greenhouse heat was maintained by day, although at night the thermometer only registered 50°. Every seed germinated, and the first seedling appeared on April 9. The seed leaf is pointed, and not unlike that of a Delphinium or Parsley seedling; in fact, at first I thought it was a Chickweed plant. The frame was kept close until April 25, when the first rough leaf had formed. After this a crack of air was admitted on fine days, the frame being closed and matted

Potato seedlings, as they had the true Potato leaf. On May 24 the top was removed from the frame, and the little plants hardened off ready to transplant out of doors.

On June 2 I took the photograph of the pan of seedlings, which were then from 2 inches to 3 inches high and nice little plants. After this they were transplanted into nice sandy loam. I was somewhat surprised to find that they now had two and three tubers on each root, being about the size of a small Pea. They were planted about six inches apart and watered in. When it was seen that they had taken hold, they were moulded up slightly, and after that had no further attention until they were dug. On July 15 the plants had grown to a foot high, and had exactly the same appearance as plants from those little tubers which slip through the fork at digging-time and afterwards germinate. On September 26 the haulms showed signs which indicated that the crop was ready to dig, and this was done, with the result that each root yielded four to five tubers ranging from the ordinary "set" size to that of a Pea. Every tuber was saved. These will be again planted this (1915) season. The shape of the tubers varied considerably, some being round, others oval, and, of course, a few, which reverted to the wild type, a long, thin, pointed shape.

At the end of 1915 the produce from these small "sets" will be lifted and sorted, the best-shaped ones being again grown on in 1916, when it will be possible to see if there are any really good new ones. It is quite possible that there might

A PAN OF SEEDLING POTATOES PHOTOGRAPHED ABOUT TWO MONTHS AFTER THE SEED WAS SOWN.

up at night. After a further three weeks of very hot weather the seedlings went ahead, having made five rough leaves on May 6. At this time they were somewhat crowded in the small pan, and about an inch high, so were carefully transplanted into a larger pan and then returned to the frame. There were very few roots at this stage, and the seedlings felt a slight check. However, on May 16 it was quite easy to see that they were

be one equal to Up-to-Date, in which case the entire stock would probably be marketable to a specialist, or the gardener could dispose of the produce himself.

The cultivation of new sorts from seed is a very fascinating business, and, as will be seen from this short description, does not entail a great deal of care or previous knowledge.

CLARENCE PONTING.

Throxenby, Great Missenden.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Peaches and Nectarines in Pots.—As soon as the fruits have passed the stoning stage, strict attention must be paid to watering. During bright weather it will be necessary to examine the pots two or three times a day, for any neglect in this matter would be disastrous to fruit trees growing in pots. Manure-water and other stimulants may now be given more frequently and with increased strength. It will be of great benefit to the general welfare of the trees if the pots are plunged to the rims in litter. The final thinning of the fruits must be done now. Thin the fruits in proportion to the size and strength of each tree. Remove all superfluous growths and keep the young growths regularly pinched. The trees may now be subjected to harder forcing, but it should be remembered that this must be done chiefly by husbanding the sun-heat in the afternoon.

Midseason Peaches.—The work of disbudding must be carried out at regular intervals, thus causing no serious check to the trees. Where the fruits have set very thickly, all those that are badly placed may be removed at once. See that the roots do not suffer for want of water after the fruits have, et, and afford plenty of stimulants to established trees carrying heavy crops.

Late Peaches.—It is sometimes desirable to retard the latest trees as much as possible, but when the flowers are open, cold draughts must be avoided.

Plants Under Glass.

Chrysanthemums.—Some of the most forward plants may now be placed in cold frames to make room for other subjects. Those recently potted must not, however, be subjected to cold draughts. Pot on later plants as they become sufficiently well rooted. In a week or two it will be safe to place the whole of them in cold frames.

Cyclamen.—As the old plants pass out of flower, remove those which are maturing seed and keep them well supplied with water. Others which are being saved to pot on may be placed in a cold frame and kept dry for a few weeks. Pot on young plants when necessary and keep them growing near to the glass in a warm, moist house.

Schizanthuses.—These and other annuals growing in pots should be liberally treated in regard to watering and feeding. Most of the plants must be supported with stakes, but let this be done with due regard for their natural habit. Make another sowing of Mignonette. This plant is always welcome in the greenhouse. A sowing may also be made on a sheltered border outdoors.

The Flower Garden.

Bedding Plants.—Many plants which are established in pots or boxes may now be removed to cold frames. This will give more room in the house to others which need to be grown on. Heliotropes, Ageratums, Lantanas, Pelargoniums, Iresines, Marguerites and various kinds of annuals may all now be safely placed in cold frames. They must, however, be well cared for in the matter of ventilating and watering, and sufficient protecting material must be at hand in the event of sharp frost. Continue to prick out seedlings before they become drawn in the seed-pan, and persevere in the boxing or potting of rooted cuttings. Plants which have been wintered in cold frames must be well ventilated, and during favourable weather the lights may be entirely removed.

The Herbaceous Border.—Large clumps of border Phloxes must be thinned, leaving only those shoots which are strong enough to flower. Some of the shoots may be used for propagating. Plants propagated last year can now be planted out, and those of *Anchusa italica* which were raised from seed last year may also be planted. This lovely border subject is easily raised from seed sown now.

The Rock Garden.—Now that growth is active, the stronger-growing plants must be watched, or they will smother some of their smaller neighbours. It may be necessary in some cases to root out some of the old plants, where young ones are at hand to replace them. If this work

of curtailing the growth of strong-growing plants is done regularly, no unsightly gaps will be made.

The Hardy Fruit Garden.

Pruning Recently Planted Trees.—There need be no delay in pruning trees which have been planted this season. Opinions differ as to what extent young trees should be pruned. Peaches and Plums planted against a wall ought to be cut fairly well back to induce growth from the base of the branches. For Apples and Pears planted in the open, the leading growths may be cut back about one-third their length. Cut well back shoots which are crossing each other, and leave ample room between the branches for light and air to penetrate right through the trees. If the mulching of young trees has not been done, no time should be lost in doing so, as this will be of great benefit in the event of a dry season.

The Kitchen Garden.

Carrots.—A sowing of one of the stump-rooted kinds must be made on a well-worked piece of ground. I believe in making small sowings of Carrots every month to ensure a good supply of young roots all through the season. Carrots growing in frames should be ventilated freely, both by day and night, during favourable weather.

Radishes.—Make small sowings of Radish on a warm border every ten days. During dry weather they must be watered frequently.

Broad Beans.—Another sowing of this valuable vegetable may be made now. In a season like the present it is advisable to sow the seeds in boxes in cold frames. Even if this is not practicable, a few seeds should be sown in boxes for the purpose of filling up gaps, which are sure to occur when the ground is wet.

E. HARRISS.

(Head-gardener to Lady Wantage.)
Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Tomatoes.—The early crop will by this date be growing freely. Do not allow the plants to starve, but top-dress them with loam enriched with a good fertiliser. White fly is usually very troublesome, and requires a fairly strong fumigation to kill it outright.

Carrots.—Make a good sowing of Carrots to succeed those growing on hot-beds and in frames. Early Nantes is a suitable variety for this sowing.

French Beans.—From now until the outdoor crops are ready, supplies will have to be obtained from cold frames. To gain time, continue to raise the plants with the aid of pipe-heat, planting out in the frames as the plants become hardened.

Brassicas.—The sowing of the main crops ought now to be done, excepting the Broccoli and some of the Kales, which are better left for some time yet. Choose a fine day when the ground is in good order, and if birds are troublesome, protect the seeds with nets.

Beetroot.—The roots from last season should keep up supplies until June or July, at which time they may still be had in excellent condition if they are properly preserved in an outdoor pit of soil, which is best situated in a shady part of the garden. For a succeeding crop, to be ready for use during August and onwards, a sowing must now be made of a globe-shaped variety.

Vegetable Marrows.—The main crop should now be sown indoors and potted on to prevent the plants starving until it is considered safe to plant in their permanent quarters, usually about the last week in May.

Fruit Under Glass.

Grapes.—Do not delay the thinning of Grapes as soon as it can be determined which berries are seedless. These should first be dispensed with; then remove the berries which tend to point inward, and remember to always preserve the berries on the extremities intact. Care must be taken that the person thinning the Grapes does not in any way come in actual contact with the bunches, or disfigurement will result.

The Hardy Fruit Garden.

Newly Planted Trees.—Trees, especially standards, are in danger of becoming loosened by the wind. It is therefore necessary to see they are duly supported, and in such a manner that the bark is not likely to become injured. Newly planted trees are apt to suffer in another respect at this season, should there be many drying winds. As a precaution the soil in which they are planted ought to be trampled firmly, and if there is danger of continued drought, a mulch of litter should be applied to each tree.

Strawberries.—Sometimes, owing to circumstances, it may not have been possible to make a young plantation during August. Instead of this, the runners which were laid in closely on a sheltered border to winter will now be showing signs of growth, and should be planted before warmer weather comes, so that they may be establishing themselves against a possible dry summer. Make the rows 2 feet 6 inches to 3 feet apart, and plant carefully, taking care not to bury the crowns.

The Flower Garden.

Gladioli.—The planting of these bulbs must not be delayed, or they will be liable to lose some of their vitality. Some varieties, notably princeps, only commence to flower when they are liable to be cut down by an early autumn frost. This trouble, however, can easily be overcome by a little attention at this season. Instead of planting out, fill boxes with some light compost, chiefly formed of leaf-soil, and start in gentle heat, eventually planting into their permanent positions when they have grown 8 inches or 10 inches in height. Other varieties to be recommended are America, Hollandia, Baron J. Hulot, Hallii, Faust and Pink Beauty.

The Herbaceous Border.—If any new plants are to be added to the collection, they should be planted now, when most plants are commencing to grow. Keep watch constantly for any slugs or snails that may be active on any of the choice and tender subjects.

Dahlias.—Unless grown from cuttings, this date is quite early enough to start the plants into growth. Do not excite growth by the use of too much heat; a temperate house will produce much stronger growths.

Roses.—It will depend a good deal both upon the state of the weather and how far the growth of the buds has advanced, but, generally speaking, almost the entire Rose pruning should be done within the next few days. If unduly delayed, there is a danger of a loss of vitality to the bushes. There is no hard-and-fast rule, but the general practice is to first remove all dead and weakly growths; then prune the remaining growths according to the purpose for which they are required. For general garden display a less severe pruning is naturally required than in the case of plants which are expected to produce exhibition blooms.

Plants Under Glass.

Single-Stemmed Chrysanthemums.—The most forward plants will now be ready for a shift into 5½-inch and 6-inch pots. Make certain that all the pots are clean before using them. Let the soil used be fairly rough. Good fibrous loam, leaf-soil and sand, with some spent Mushroom-bed manure, will make a good compost. A small quantity of soot and an approved fertiliser can be added. As soon as potted, confine the plants to frames, which should not be ventilated too freely for a few days. Be very careful in applying water. On bright days a spraying with the syringe will be of great help.

Gloxinias.—More tubers of these choice flowering plants should be shaken from the spent soil and started in a light compost. Place them a safe distance apart in boxes and keep in the stove. Gloxinias, although benefiting from a humid atmosphere at all times during their growth, nevertheless resent the water actually on their foliage. Young plants resulting from seed sown during January will now be ready for pricking off, and this is best done in boxes of soil, which should be light and flaky, with plenty of silver sand included.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine,
Bart.)
Castlemilk Gardens, Lockerbie, N.B.

ANNUALS FOR THE ROCK GARDEN.

THE right or wrong way of using an assortment of plants of annual growth in the rock garden may be safely left to individual taste and circumstance, but there is no doubt whatever that it is possible, by the introduction of suitable varieties, to considerably add to the brightness and interest of the rockery at a time when a great many other, and perhaps more genuine, rock garden plants are beginning to wane.

Thanks to the untiring efforts of some of our leading seedsmen, there is a large selection to choose from, thus allowing personal taste as to colour to be gratified to a large extent. The popularity of a walk through the rock garden during the cool of the evening is quite recognised, and if near the approach to, or path from, the garden some annuals noted for their fragrance are used, the result certainly repays our trouble.

When considering suitable plants for such a purpose, the Night-scented Stock (*Matthiola bicornis*) will at once come to mind, and right well does it deserve recognition, for its fragrance is delicious. Mignonette also has its host of admirers, and should be "squeezed" in somewhere; and another plant, bearing, as it were, Mignonette-like spikes and emitting in the evening a delightful sweetness, is the South African introduction, *Habenstraitia comosa*. It is white, with blotches of orange, and grows about one foot or eighteen inches high. *Schizopetalon Walkeri*, growing from 6 inches to 12 inches, although perhaps not having much claim to a "display" with its queerly arranged white petals, is worth a place for its sweetness alone. In concluding this brief list, I would fain plead for the Tobacco Plants (*Nicotiana*).

Admittedly, the rampant growth of the majority shuts them out from many positions, but where it may be found possible to use, perhaps, the dwarfer ones, they most certainly should be, for they fill the evening air with their fragrance.

For general use on and around the rockery quarter the following list may be found useful:

Name.	Height and Colour.	Remarks.
<i>Abronia umbellata</i>	Rose (trailer)	Really perennial, does well as annual.
<i>Anagallis</i>	About 6in., blue and scarlet	Delights in sun; half-hardy annual, or sow end of April outside.
<i>Alyssum</i> , annual	From 3in. to 9in., white	Useful for small crevices near pathways.
<i>Asperula azurea setosa</i>	From 9in. to 14in., pale blue	Lasts well; hardy annual, scented.
<i>Antirrhinum</i>	Known as "dwarf," various tones	Should be given a sunny spot.
<i>Campanulas attica and attica</i>	About 6in., violet and white	Both hardy annuals and very free.
<i>Candytuft</i>	From 6in. to 12in., mixed colours	Of easy culture.
<i>Coreopsis</i>	Those known as "dwarf"; for preference, crimson and golden	Very showy and not fastidious.
<i>Convolvulus minor</i>	Generally 1ft., the blue and white best	Give open spot.
<i>Delphinium Blue Butterfly</i>	12in. to 15in.	Makes a very bright patch indeed.
<i>Eschscholtzia Miniature Primrose</i> ..	3in. to 6in., lemon shade	A little gem.
<i>Ionopsidium acaule</i>	About 2in., lilac or mauve	Of free growth; pretty in crevices.
<i>Leptosiphon hybridus</i>	From 2in. to 4in., many shades	Blooms freely; hardy annuals.
<i>Lupines</i> , annual	Height 1ft., several shades	Looks well against a rough stone.
<i>Nasturtiums</i> , dwarf	From 6in. to 12in., many lovely shades ..	Exceedingly bright; poor soil and a sunny crevice required.
<i>Nemesias Suttonii and hybrid</i>	From 6in. to 12in., mixed, including a lovely orange shade	Half-hardy annual; worthy of good soil and position.
<i>Oenothera</i> (Evening Primrose)	6in. and 12in., rosea, <i>Drummondii nana</i> (yellow)	Useful as adding variety.
<i>Phlox Drummondii</i>	6in. to 12in., mixed	Very useful if sown rather late outdoors; free.
<i>Phacelia campanularia</i>	About 9in., lovely bright blue	Prefers light, warm soil.
<i>Papaver nudicaule</i> (Iceland Poppy) ..	From 9in. to 14in., many shades	Strictly perennial; does well as annual if sown early.
<i>Sedum caeruleum</i>	3in. or 4in., pale blue shades	Looks pretty in pathway crevices.
<i>Virginian Stock</i>	6in. to 9in., several colours, crimson best ..	Generally used for early work, but if sown end of March does well.

Serlby Gardens, Bawtry, Yorks.

THE PRESENT NECESSITY FOR CULTIVATING VEGETABLES.

SOME REASONS AND SUGGESTIONS.

THAT most people, particularly those of the amateur gardening fraternity, have read the numerous articles and paragraphs that have appeared from time to time in various newspapers and periodicals dealing with the supply of vegetables in war time, may be assumed by the jocular remarks one frequently hears about "turning the garden this year into a vegetable patch" or "decorating the Rose borders with Cabbages," and so on. While many of these articles are most helpful and serve a useful purpose, very few, if any, go to the root of the matter by giving reasons why it is vitally necessary that those who are unable to serve in the forces of the Crown should help at home by making every effort to increase the food supplies, even if it is only sufficient, or partly so, for their own consumption.

The rapid increase in the cost of food is only one of the reasons, and not the greatest, as I shall endeavour to illustrate. The principal and outstanding feature is the limited supply of labour. The dearth of labour has always been a serious problem in rural districts, and it is a moot point whether the large area of land under pasture in this country is not largely due to this. Education, low wages, the absence of good housing accommodation and the attractions of town life have each contributed their quota to the problem. In every village throughout the land were to be found reservists who, on the outbreak of war, were called to the Colours; since then every village and hamlet has given its share, and more than its share in many cases, of its bravest and best to the New Armies. The absence of this vast army of labour when the majority of crops need to be sown for future supplies can only have one result at harvest time, whether the war lasts the proverbial three months or three years.

The same problem will have to be faced in such enormous grain-producing countries as Russia and Canada, who have each mobilised enormous bodies of men for the war. Even supposing large bodies of men are drawn from the towns for the Army, the dearth of labour resulting therefrom would

attract the rural worker now as in the past. France and Belgium have been providing large quantities of fruit and vegetables for our markets. If the former is able to spare any now or in the near future, which is very much to be doubted, the supplies would be very limited; certainly we shall get none from the latter country this year, at any rate.

Without undue pessimism, and taking all these facts into consideration, one can only come to one conclusion, and that is, if we are to avert or wish to minimise the inevitable result of the present state of affairs, it is every person's duty to do his or her utmost to obtain from such land as is in their occupation all they possibly can.

It should be borne in mind that our present food supplies are the fruits of last year's harvest, and that it is upon the next harvest that the effects of the war will be felt. The cost of food is increasing, as already stated, but he would be a daring individual who would predict the prices that will rule next winter. Already we hear of market gardeners who are restricting their crops to those kinds that require the least amount of labour.

Many gardeners probably will hesitate at giving up their cherished flower borders to grow vegetables—and who shall blame them?—but there are more ways of killing a cat than (trying) to drown it. Why not compromise? Take Beet-roots, for instance. Two or three seeds sown here and there will provide beautiful foliage plants, and when the frosts come and the flowers are all gone, there is one useful article of food in the ground ready to be dug and prepared for the table. Parsnips, again, with their Fern-like foliage; a few seeds judiciously planted, surely they would not look amiss growing among the flowers; and what more useful article of vegetable food for the winter could one grow? Even the humble Swede, so often despised, possesses a foliage that would put to shame much of the foliage of border favourites and, to those who are partial to them, form an excellent article of vegetable food.

Apart from these suggestions, if only the various plots of prospective building land in and around our towns could be utilised for growing vegetables until such time as they were required by the owners, it would help matters very much. Surely some of the owners, if not all, would be willing to grant the use of their land, on a yearly tenancy, for a reasonable figure, which would be far better than leaving it idle and unproductive, as is only too frequently the case. We have in London some striking examples of what can be done in this respect; and through what better medium could this be effected than the local horticultural societies, who would undoubtedly be only too glad to undertake such a task as apportioning them to prospective tenants, of whom there is not likely to be a dearth?

It is not too late to start such a scheme, although no time should be lost. Ground that could be tilled now would provide good crops of Potatoes and many other vegetables by the autumn. It would be doing a public service if willing owners could be induced to supply the secretary of the society in the district in which their land lay with particulars of the ground available; or, better still, that the secretary should approach the owners, providing he was satisfied that there would be a demand for such by the residents. The necessary negotiations could easily be carried through by the committee of the society.

ERNEST C. CROSS.

(Hon. Secretary, Hale End Horticultural Society.)

H. TURNER.

THE EVESHAM VALLEY IN EARLY SPRING.

THESE are few more interesting places in which to spend some days in the early spring months than the Vale of Evesham, which has of late years rightly been regarded as the centre of the fruit-growing and market-gardening industry in this country. This eminent position has not been brought about merely by chance, but is rather the result of a combination of several circumstances, chief of which is the particularly fertile soil that is found on almost all the land. To this must be added the inborn industry and practical application of several generations of the tenants and owners and the successful results of their labours. At the present time early spring work is being pushed on rapidly in every direction, spraying with lime-wash to prevent the eggs of the apple-sucker, or psylla, from hatching being effectively carried out. The larvæ of this pest, if allowed to hatch, enter the newly opened Apple buds and do incalculable damage by sucking the juices from the foliage and flowers.

In the actual cultivation of the soil it is a revelation to the average fruit-grower of other districts to see to what an extent horse-power is employed. So skilfully has planting and subsequent pruning been done that manual labour in tilling the soil has been reduced to an infinitesimal point, and considerable ingenuity is displayed in designing and making implements that will do the greatest amount of cultivation in the shortest time. At The Norrest, near Malvern, Mr. F. Paget Norbury had a plough in use that turned a yard width of soil at one time. This had an ordinary double breast behind, with two single breasts about two feet in front, and turned the soil up to a depth of about four inches to five inches. One journey between two rows of trees, to be cut at right angles by another journey, turned over an amount of soil that would be quite impossible with an ordinary plough, owing to the difficulty of working it under the branches. This plough is only made under Mr. Norbury's directions. Subsequently the owner informed me that springtoothed harrows, specially designed for the purpose, would be used to tear the soil to pieces, so that, by the early days of summer, a fine tilth would be the result. The value of this in conserving the natural moisture of the soil during the hot days of summer can scarcely be over-estimated, and would stand the grower in better stead than unlimited supplies of artificially applied water.

In most districts, bush trees, *i.e.*, those with branches springing from near the ground, appear to be the most favoured, and the diagonal system of planting is almost universally adopted. Thus a tree in one row will be placed midway between its two neighbours in the next row, so that the trees appear in straight lines from whichever point they are seen. The advantage of this in the horse-power cultivation already referred to is obvious, and enables the cross-ploughing that has proved so advantageous. The system of planting one row of a strong or fast growing variety, such as Bramley's Seedling, and the next with a slow-growing sort, such as James Grieve, is also largely

favoured, the growers rightly contending that it is better for the trees and easier for cultural purposes.

In a number of instances single cordon trees, trained at an angle of about 45°, and sloping to the north, are being tried. These are fastened to taut galvanised wires in rows 8 feet apart, and the trees about two feet asunder. In this system of cultivation, however, the Evesham Valley growers are rather behind those of one or two other counties, where cordon trees have been grown on a commercial scale for some years, and apparently have proved successful. Such trees have several points in their favour. They are easily attended to in the way of pruning and spraying, practically all the fruit is of first-class quality, and it is surprising what a vast number of trees can be grown on an acre of land. As maiden trees, *i.e.*, one year old from budding, are usually planted, the cost of trees is not excessive.

The protection of fruit blossom from spring frosts is gradually spreading, although some of the older growers regard it with a good deal of scepticism. The use of smudge fires has been successfully adopted in several instances, and although the initial outlay for apparatus may seem rather expensive, it is spread over a number of years, the actual yearly cost for fuel, naturally, depending on the number of times it is necessary to light the fires. Soft coal is the fuel used, and this creates a dense smoke with a certain amount of heat, the two combined forming an effective protection. A maximum and minimum thermometer, fixed in the fruit plantation, is connected by wires to an electric alarm in the employer's or foreman's bedroom, and when 2° of frost are registered, the mercury makes the connection and sets the alarm going. Funnel-shaped Colorado heaters were used at first, but these are being gradually supplanted by those known as the Norbury, designed by Mr. Norbury, who was the pioneer of the system in the district.

Growers all over the valley are keenly planting the Purple Pershore Egg Plum, which is a purple-fruited form of the older Pershore Egg Plum, a variety that has stood them in such good stead in the past. Though of no use for dessert, it is an excellent variety for preserving, and it is hoped that the purple variety will prove its equal in usefulness and fruitfulness.

The dreaded big-bud mite of Black Currants is being gradually exterminated in two ways. One is the ruthless war that is waged on it during the winter months by rooting out and promptly burning any bush that has swollen, rounded buds, and the other is by spraying about every ten days from mid-March until well into April with an approved insecticide, usually Quassia extract and soft soap. The latter period is when the mites are travelling, and is the only time of the year that they can be reached with insecticides.

A pest that is troubling many growers is silver-leaf of Plum and kindred trees. In common with many other fruit-growing districts, it is largely on the increase in the Vale of Evesham, and, considering how carefully the trees are tended, it would seem that the general belief that spores of the fungus can only be produced on dead wood is erroneous. Certainly this fungus is one that needs fuller investigation and more concerted measures if it is to be checked and finally exterminated.

F. W. I.

THE CHARM OF COMMON SPRING FLOWERS.

A GARDEN in springtime that has been thoughtfully planted possesses a subtle charm not obtained at any other season. How welcome are those flowers that brave bitterly cold winds, occasional sharp snaps of frost, and appear at a time when deciduous trees have scarcely started into growth! The Daffodil, Primrose, Wallflower and Leopard's Bane are but a few of the host of garden flowers that are seen to full advantage at this season. The earliest attempts at spring gardening in this country consisted of ribbon borders, wherein Hyacinths, Tulips, Primulas, Wallflowers and Daisies were planted with marked regularity. Happily, this type of spring gardening is rapidly giving way to the less formal and more natural grouping of flowers. Daffodils now find suitable homes on grassy slopes or in old orchards, and if the soil is suitable, the bulbs increase and flower with greater freedom year by year.

When flowers are left to their own resources, as in the case of those that are naturalised in grass or woodland, it is important that the soil and situation should favour their development. It is well known that the common Primrose of our woodlands will not thrive for any length of time in very light and over-drained soils, yet at the same time Daffodils and Bluebells may flower profusely year after year in the garden where Primroses fail. The question of a suitable selection of spring flowers for naturalising in certain gardens is governed by the surroundings, and the most reliable guide will be found in those flowers that succeed naturally in the neighbourhood.

On a hillside, where either Heather, Broom or Gorse may clothe the surrounding slopes, is surely the ideal site for a Heath garden, the real charm of which is found in the fact that flowers may be had not only in the spring, but in every month of the year. Banks of Broom and Gorse would be quite in keeping in such a place. If the wild Daphne or Spurge Laurel, which is one of the earliest of our native flowers to open, is seen as an undergrowth in neighbouring woods, the chances are that the cultivated and more powerfully scented Daphnes will flourish, providing they are not planted in too dense a shade. Should the Wood Anemone now form a carpet of white to the copses, in gardens near by the Windflowers may be successfully cultivated. If in the vicinity the native Fritillary or Snake's-head is discovered in the pastures—and alas! there now are comparatively few places where it does occur in quantity—it could be induced to take care of itself in the wild garden. It occurs, among other places, in the meadows around Oxford, where children gather the flowers in handfuls. In certain villages of Wiltshire the Fritillary is known by the ugly name of Toad's-heads, from the marbled brownish flowers. The natives say that the colonies of Toad's-heads are always moving, though but slowly, in an easterly direction. Within the memory of some of the oldest inhabitants one colony is said to have moved across several fields. To the natives this is a source of wonder, but it may be accounted for by the westerly wind carrying the seeds in an easterly direction. In the rock garden the perennial Candytuft, Aubrietias, Chionodoxas and Rockfoils are prominent among the good things of the spring.

H. C.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Two Daffodil Chapmans.—I ought to have made it quite clear that Mr. Chapman, whom I alluded to in my "Daffodil Notes" in *THE GARDEN* of March 20 in connection with Mr. Bourne's exhibit, is not Mr. F. Herbert Chapman of Rye, and that the only connection between the two is the similarity of name and taste.—JOSEPH JACOB.

Copper Preserving Pans.—I cheerfully accept N. Cobb's wise caution concerning copper cooking utensils on page 134, issue March 20. Truth to tell, it is so many years since I banished all such toxic terrors (only one superannuated copper kettle remains as an ornamental relic fondly cherished by cook) that I had quite forgotten

and put the underskin through a mincing machine. The pips are placed in boiling water for five minutes, the water is then strained and the pips thrown away, and the water added to the remainder, the whole being boiled for two hours. Sugar is then added, and the composition boiled for another twenty minutes. It seems to me that the above is a more simple method than that recommended by "Anne Amateur."—R. P. B.

Crocuses at Kew.—Few plants denote the return of spring more joyfully than the Crocus. Whether grown in the small villa garden in dozens or spread broadcast in their thousands, as in the grass at Kew, the white flowers of the "cultivated" forms of *C. vernus*, or the golden ones of *C. aureus*, equally give pleasure at this uncertain season. From a cultural point of view many of the Crocuses present little difficulty. In the garden, provided the soil is not too heavy and the drainage is good, if the corms are left

Technical Terms Used in Describing Daffodils.

I hope you will not be too horrified when I tell you that I only read your issue of March 13 on March 19. Dreadful neglect!—at the time, too, when notes are appearing on bulbous matters from the able pen of Mr. Jacob. It is anent one of the said articles that I wish to make a few remarks. On the whole, I am fully in sympathy with what Mr. Jacob says on the subject, but there are one or two points on which I cannot agree. First, under the heading of "Hooded Flowers," he gives as an example Lucifer. Now, is this fair treatment for poor old Lucifer? To my mind, this variety is only "hooded" when it has "caught cold," as it did in the almost arctic temperature in the Royal Horticultural Society's Hall on the night before the Forced Bulb Show. Certainly, after that unfair trial (for indoor blooms), Lucifer did look "hooded"; in fact, one could see in Messrs. Carter's exhibit good blooms not only hooded, but with segments bent over beyond recovery. But when Lucifer has a proper chance to display its charms, it is quite as flat as the average run of the section to which it belongs; while, as every grower knows, although a frail-looking flower, it will outlast nine out of ten varieties with which it may be associated as a cut flower. I cannot give in to Lucifer being a hooded flower! In the next paragraph one reads "claw-shaped or elliptical." It took considerable thought for me to arrive at what was meant by an elliptical flower; then it dawned upon me that the *profile* of the flower was intended. I venture to think that very few people would gain much information by the description of an elliptical bloom, for all the other descriptive terms are applied to a full-face view of the flower. Again, it would seem that every flower not perfectly flat might be described as elliptical, only in some cases the ellipse would be a very narrow one. No; "claw-shaped" I can do with, but "elliptical" seems unnecessarily abstruse. Again, I do not see "eye to eye" with Mr. Jacob when he gives Frank Miles as an example of "twisted" segments. A bloom of Frank Miles is before me as I write, and I have known this variety for a good number of years, but have never looked upon

the segments as twisted. Is not "incurved" a truer description of these folded-in segments? Patience, Mr. Editor—one more item and I have done! "Flanged." This is such a very mechanical term that one seems to associate it rather with railway lines than with flowers, and a "flange" seems to convey a hard, right-angle projection, seldom, if ever, seen in the edge of a Daffodil trumpet. Would not "reflexed," with qualifications such as "slightly," "much," &c., meet the case? If I should have used the term "flanged" in describing Daffodils in my list, I will promise to alter it if Mr. Jacob will accept "reflexed" as a substitute. In conclusion, I would say that the idea of having a greater uniformity of terms wherewith to describe Daffodil blooms is extremely good, and should, if generally adopted, save much confusion in the minds of catalogue-studying amateurs.—J. DUNCAN PEARSON, *Lowdham, Notts.*

• A CHARMING GROUPING OF CROCUSES IN THE GRASS AT KEW.

anyone in these hygienic days still used them.—ANNE AMATEUR.

Customers of Bees, Limited.—We have received a number of orders and enquiries without name and address, or with insufficient address. In some cases the post town only is known by means of the postmark on the envelope; but at the moment there are about twenty orders which we cannot deliver for one or more of these reasons. Some are accompanied by cash.—BEES, LIMITED, *Liverpool.*

Recipe for Orange Marmalade.—My wife has made delicious marmalade from this recipe at a cost of 1½d. per pound in past years, but this year the increased cost of sugar has increased the price of the marmalade. I give the materials in the lowest units: 1lb. of Oranges, 6lb. of sugar, and twelve teacupfuls of water. Wipe the Oranges with a damp cloth, grate off the yellow rind,

undisturbed they multiply freely, while planted as shown in the accompanying illustration, upon a turfy knoll, in the spacious grasslands of Kew, they thrive untouched for very many years, and each returning spring sees their ranks thickened by matured offsets, increasing still further the refulgent splendours of the golden stretch as viewed from many a sylvan glade. Where the alpine garden is available, with its extra sharp drainage and protected nooks for the cultivation of these and similar bulbous plants, many dainty and attractive species may be grown with ease, and January is ushered in with the golden flowers of *Crocus vitellinus*, soon followed by *C. Imperati*, *C. Sieberi*, and *C. chrysanthus*, while the story is then taken up by the purple-feathered cups of *C. versicolor*, *C. tommasinianus* and the varying natural forms of *C. vernus*.—REGINALD A. MALBY.

Mildew and Green Fly on Roses.—Could ask you through your valuable paper to enquire of Mr. Thackeray Turner, who in the issue of February 6 had an article on "Green Fly and Mildew on Roses," how much guano he would add to two pails of water (my Rose garden being small), and if he allows it to be put over the plants when watering, or only round the roots? Also, "Dorking lump lime" is ordinary lime; I must wait after slaking until it is dry before putting it around Roses; if this is good for all Roses; and if there is any danger of harming them? I am a very great amateur. I suppose this is easily seen.—AMATEUR, U.S.A.

Roses and Mildew in New Zealand.—I have been very interested in the correspondence re mildew on Roses. I grow 400 or 500 plants, but I have no mildew. One plant of Her Majesty had it one year, but I put it down to its being an old plant and worn out. We have a long, hot summer, and generally very dry (we have only had 3 inches of rain in eight months). The soil is very rich, with a sandy subsoil—old swamp land. It seems to me as if climatic conditions had everything to do with mildew. In this dry season the colouring of some of the Roses, such as Sunburst, Le Progrès, Mrs. Waddell, Souvenir de Stella Gray and Juliet, has been gorgeous. The last named evidently likes the dry warmth, as the plant looks so healthy and has bloomed better than ever before. I am a fairly successful amateur gardener and take a great interest in THE GARDEN.—M. EDITH TOSSWILL, New Zealand.

The Colouring in Forced Bulbs.—It is fairly generally known that the forcing of a hardy plant in many cases modifies the colour of the flowers, the tendency being to blanch them. Thus, a pale pink summer Chrysanthemum generally develops white, or almost white, flowers. The same thing is noticeable in Tulips. In the case of Tulips, the blanching can be more easily accounted for, as it is the common custom to shade the plants for a time in order to lengthen the flower-stems. I had ocular demonstration the other day, however, that this loss of colour is unnecessary. On entering the shop of a West End Edinburgh florist, I was shown four lots of that lovely double pink Tulip Murillo, purchased from different sources. No. 1 was perfect in colour, the others, respectively, showed loss of colour, till No. 4 was pure white. Again, I was shown different samples of Narcissus poeticus ornatus. With one exception the edging of the crown, as is usual with forced plants, had suffered considerably by the loss of colour. The one exception showed the red edging (the charm of the flower) in a state of perfection. This modification in the colouring of forced flowers is generally supposed to be entirely a question of light; but the grower of the perfectly coloured N. P. ornatus attributes his success to quite another cause, viz., to the fact that while the usual practice is to stand the boxes of bulbs on stages in the forcing-house, he stands them on the earthen floor of the house, thereby keeping the roots cool and in a more equable condition, both as regards temperature and moisture.—CALEDONIA.

Home-Grown Vegetables and Our Food Supply.—The announcement of the stupendous prizes for collections of vegetables offered by the *Daily Mail* will surely be acknowledged by all growers and exhibitors to rank with the various other schemes promoted by that publication in its efforts to arouse sensation, and, to use the

Western phrase, "To lick Creation." Of course, no one will dare to doubt that the finest show of vegetables ever staged will be the outcome of such a record prize offer. The owners of large gardens, where plenty of available space for growing crops exists, and also cottagers who live in the happy environment of pure country air, may rest assured that they will stand better chances of success than their neighbours who live in the vicinity of the smoke and industrial life of our great cities and towns. It is for these thousands of artisans that I would beg a little of your valuable space, in the faint hope that some information may be recorded for any encouragement that may be shown to them—the dwellers of the suburbs.

The purpose of offering such prizes, as the proprietors of the *Daily Mail* are doing, is to stimulate and encourage the growing of vegetables at home, which is both desirable and important at all times, but especially so during this crisis of our national life. Now, a large percentage of houses in Suburbia do not possess large tracts of garden space, but are usually described as being so many feet broad and long. The residents, therefore, cannot hope to do more than grow a few things, certainly not a collection of vegetables for exhibition. It is patent to all that we have around us very many people who are, however, interested and enthusiastic in the small area of gardens attached to their homes, yet these thousands of people are almost entirely lost sight of in the matter of encouragement of their pastimes and hobbies. With regard to the question of increased cost of living, however, these are the very people who feel its effects in every way. It must be granted that every help one can give these residents in the way of friendly advice and good counsel to help them to obtain the maximum of produce from their minimum of space is worthy of commendation.

The suggestion that local horticultural committees should be invited to act with a view to promoting the home-growing of vegetables is a worthy one, and which, if acted upon with true patriotic spirit, cannot fail to accomplish great things. Many local flower shows are being abandoned during this "European stocktaking," yet if their committees got to work in order to obtain funds, so as to be able to award a few prizes to artisans for the best-stocked gardens of vegetables (not allotments), I feel certain an appreciative public would give "strength to their arm." Not only that, but they would at the same time keep in touch with their old members, and perhaps foster an extended patronage for their society and its future shows. In districts where shows are not held, a programme of awards might even be carried out as a parochial matter, and perhaps with advantage, too. The gardeners would, I am certain, fall in with any scheme in which they could help their fellows in industrial life by giving of their counsel and advice to those who desire it, or, by practical instruction if necessary.—W. HOLTOM, *Bearwood, Smethwick, Staffs.*

FORTHCOMING EVENTS.

April 13.—Royal Horticultural Society's Daffodil Show, Vincent Square, Westminster, 1 to 7 p.m.; April 14, 10 a.m. to 6 p.m.

April 14.—The Hereford Spring Flower Society's Show at Hereford; hon. secretary, Miss Alice Barneby, Brockington Grange, Bromyard, Hereford. Royal Horticultural Society of Ireland's Spring Show at Balls Bridge, Dublin (two days).

COLOUR CHARTS: WHAT IS WANTED.

(Continued from page 148.)

EVEN if (as is to some extent being done) the colour description of novelties is based on any particular code or chart, it only happens that when it is compared with an older well-known flower bearing an exactly similar description in the same catalogue it is found to be entirely different, and so the purchaser is just as badly off. Of course, it would be possible to describe Delphinium Electra something like a doctor's prescription, thus: "'Rép. de Coul.," p. 221; Nos. 2 to 3; Centre, p. 11"; and so on. But I can hardly imagine that the recipient of such a catalogue would pay much attention to it.

It therefore resolves itself into a series of questions. First: Who shall undertake the revision of existing colour descriptions and act as an authority in the future for the correct classification according to a recognised standard? Second: Which existing standard shall be adopted or adapted? Third: Whether the various horticultural societies or the trade as a whole would consent to recognise such an authority and act on its decisions? Fourth: What would be the best means of popularising such an undertaking so that nurserymen would think it worth while making a serious effort to bring their descriptions into line? Fifth: Who will pay?

With regard to the first, I think there can be no two opinions on the subject that such effort should be allied to the work of an influential existing organisation, such as the Royal Horticultural Society. Presumably the work would have to be conducted on the laboratory principle, and if a complete revision of descriptions of all the flowers *only* is undertaken, the volume of work during the first two or three years would be enormous. The advantage of associating such work with the Royal Horticultural Society would be that certificated novelties would automatically receive an authoritative description at the time of introduction, and that the records would be available for reference to the vast garden-loving public who have, or will, become members of the society.

With regard to the second consideration, as to what standard shall be adopted or adapted, in my opinion there can be only one, and that is the most comprehensive, viz., the "Répertoire de Couleurs" of 1905, brought up to date and adapted by the addition or correction of those features in which it has been found lacking for English users.

The third question I am unable to answer, but have a shrewd suspicion that it depends on the answer given to the fourth, which is, as far as I can see, as follows: The desire for such an effort on the part of someone does exist among the gardening public. I am constantly coming across evidence of this fact, and once it is realised that the average catalogue description can be referred to a handy, compact and comparatively cheap work of reference, nothing further will be needed to make such a work popular; but the "Répertoire" is too immense. Hundreds of the colour shades given therein can only be required once in a lifetime; hundreds more a very few times. As even these will be required at some time, it would seem desirable that it should be retained as the standard, and that a handier, less comprehensive and cheaper work

should be produced containing those colours most required, but retaining the reference numbers of the parent work. I believe there would (in normal times, of course—not perhaps in the midst of war) be no difficulty in obtaining sufficient subscribers to meet the initial cost of such a work, providing it was recognised that the authority was reliable and permanent.

Mr. Jacob appears to advocate a system whereby many colours are given on one sheet. If this is his opinion, I am afraid I cannot agree with him, because nothing detracts more from the individual value of any colour than having it associated in the vision with others. To get the truth of a colour, one must have it pure. I would rather advocate a system in which every individual shade can be temporarily isolated. I have in mind a simple device that could be adopted, but space forbids explaining it now.

The fifth question, as to who will pay, I must also leave unanswered.

There is just one curious fact outstanding in Mr. Jacob's article—that, whereas he quotes attempts to solve this problem by people who have all foreign *looking* names—"Blanc" and "Kohn" in America, "Klincksieck" and "Valette" in France, and others—there does not seem to have been any attempt on the part of an Englishman in England. And yet one would have anticipated that in this land of beautiful gardens, in which Bacon wrote that "When ages grow to civility and elegance, men come to build stately sooner than to garden finely, as if gardening were the greater perfection," and in which we are annually coming to appreciate more and more the advice of Miss Jekyll to "so use our plants that they shall form pictures in our gardens" (I quote from memory), the demand for such a colour chart would have been recognised and met long ago, but so far we are content to rely on France and America. Is this due to our not having fully arrived at that state of "civility and elegance," or to a commercialism that produces a Royal society reputed to be "rich beyond the dreams," &c., or what is it?

If any evidence of the confusion that exists is required, the following instances should suffice: In THE GARDEN column next to Mr. Jacob's article Phlox Etna is described as "crimson scarlet"; Robinson's "English Flower Garden" gives it as "orange red"; Messrs. R. Wallace and Co.'s catalogue, "deep scarlet, maroon eye"; and Messrs. Gauntlett and Co.'s catalogue, "salmon scarlet." Now take Erigeron speciosus: Gauntlett, "rich mauve"; "English Flower Garden," "purplish lilac"; Wallace, "blue with yellow centre"; while by the same three Astilbe Davidii is described as "rosy purple," "mauve" and "reddish purple" respectively. In the above instances I have only referred to the descriptions quoted. GEORGE DILLISTONE.

BEAUTIFUL SPRING-FLOWERING TREES AND SHRUBS.

THE ALMONDS.

THE group of the Prunus family which is distinguished by the name of Amygdalus is composed of a number of distinct species, some of which grow into trees 25 feet or more in height, while others are mere shrubs. All have distinctly attractive features, but there are two species which stand out conspicuously

is obtained from the bitter kind which is used for flavouring purposes, &c. The type is well known in this country as a bushy-headed tree 15 feet to 25 feet high, bearing in spring a profusion of pretty rose-coloured flowers, each of which is about one and a-half inches across. It is better suited for gardens in the South and West than in the North, and gives excellent results in many places on the outskirts of London.

There are many varieties, of which one of the most distinct is macrocarpa. Its flowers are much larger than those of the type, and the fruits are also larger. Pendula is another distinct variety with almost white flowers; while præcox

or persicoides as it is often called blossoms two or three weeks in advance of the type, often being at its best about the middle of February. But the two most important varieties are amara and dulcis. The former produces the bitter Almonds of commerce, from which Almond oil, a poisonous product containing prussic acid, but used in small quantities for flavouring purposes, is obtained; and the latter is grown for the sake of its sweet kernels, which are so popular for dessert and confectionery. An idea of the importance of this tree may be gleaned from the fact that during the year 1913 157,793 cwt. of Almond kernels, valued at £888,138, were imported into the British Isles. They came from various countries, such as France, Portugal, Spain, Canary Islands, Italy, Asiatic Turkey, and Morocco. Spain headed the list of exports with 66,915 cwt., valued at £381,913, followed by Morocco with 37,422 cwt., worth £217,621. The kernels of most of the fruits grown in this country are quite wholesome. All the forms of the common Almond grow freely in ordinary garden soil, and in this country they are usually budded upon Plum stocks.

P. davidiana.—This Chinese species was introduced to Europe in 1865, but it has only been grown widely in British gardens for about twenty-five years. It will probably attain the average height of the Almond in this country, although most of the trees met with are below 20 feet in height. The branchlets are long and slender, and from axillary buds on the leafless branches

attractive white or pinkish flowers, according to the variety, are produced early in the year, sometimes as early as the third week in January, sometimes as late as the first week in March. Fruits are not produced here, probably by reason of inclement weather at flowering-time. During a period of mild weather in February it is often a very beautiful object, but, unfortunately, the flowers are sometimes spoiled by frost or by cold winds. The white flowers of the type make it an excellent subject for planting against a background of evergreen foliage.

P. nana.—Several common names, such as Dwarf Almond, Russian Almond and Crimean

A YOUNG TREE OF THE COMMON ALMOND (PRUNUS AMYGDALUS) WITH A BACKGROUND OF EVERGREENS.

among others, both by reason of their decorative and economic value, these being Prunus Amygdalus (the common Almond) and Prunus persica (the Peach). In the following notes attention is directed to these and other species which are worthy of consideration for garden decoration.

Prunus Amygdalus.—This species is widely distributed in the Mediterranean region throughout Southern Europe to Asia Minor, where it not only forms an ornamental flowering tree, but is of great commercial value by reason of its fruits, the kernels of which are extracted and used for various purposes, those of the sweet variety being used for dessert and confectionery, while an oil

Almond, are associated with this charming little plant. It may be justly called a miniature representative of the common Almond, for although a dwarf bush often less than 3 feet in height, its flowers, foliage and fruit resemble those of the ordinary Almond on a reduced scale. A native of Southern Russia, it was introduced to this country two and a quarter centuries ago; but, like many other choice shrubs, its merits were, comparatively speaking, unknown a quarter of a century ago. Its rosy red flowers are about three-quarters of an inch across and borne freely from axillary buds on the previous year's growth. There are several varieties, the two best being *georgica* and *essleriana*. The last named has very fine and richly coloured flowers. The white-flowered variety *alba* is decidedly inferior to the type. *P. nana* rarely perfects fruits in this country, and is sometimes found difficult to propagate. It, however,

rose; *flore sanguinea pleno*, red; *Clara Meyer*, rose; *magnifica*, crimson; and *flore rubro pleno*, red. Although in each case the flowers are more or less double, most of the varieties produce fruits, and in some seasons a good crop. These fruits are quite palatable, and are well suited for making into jam. The purple-leaved variety *foliis rubris* bears, perhaps, the best fruits. The home of the Peach is considered to be China, but it has not been found in a truly wild state, many of the apparently wild trees being doubtless escapes from cultivation. All the double-flowered varieties are excellent for forcing.

***P. triloba*.**—This Chinese species is better known by its double-flowered variety than by the type, as it is a much superior plant for decorative gardening. Bushes of the single-flowered form may grow 12 feet or more high, and they bear pinkish flowers nearly an inch across during late

HARDY PRIMULA: NEW AND OLD SPECIES.

PLANT collectors in the last few years appear to have spent a good deal of their time in collecting Primulas. From Western China and the Himalaya new species have poured into this country at such a rate that it is difficult to keep pace with them. At the Primula Conference, held in London under the auspices of the Royal Horticultural Society last 1913, no fewer than 140 species were recognised from China alone. Needless to say, many of these are of little use as garden plants, while some of them are tender; nevertheless, a fair percentage is destined to hold a place in the gardens of this country.

PRIMULA ROSEA, A DELIGHTFUL PLANT FOR THE STREAMSIDE.

PRIMULA SIKKIMENSIS, THE HIMALAYAN COWSLIP.

PRIMULA DENTICULATA, GROWING AS A CREVICE PLANT.

grows quite well from layers, which is an infinitely better means of propagation than the alternative method of grafting upon Plum stocks.

P. orientalis is only suitable for walls or for borders in the warmest parts of the country, as it is a native of South-Eastern Europe and Western Asia, and too tender for general culture in Great Britain. Its greatest attraction lies in its silvery leaves, the flowers being borne with less freedom than in other species, and the rosy colour being less attractive than in the last-mentioned species.

***P. persica*.**—This is well known as the parent of the cultivated Peaches. All the forms of fruiting Peach are very beautiful when in flower, but for decorative gardening they are inferior to the many varieties which bear double flowers. These varieties may have white, rose, red or crimson blossoms, a good selection of varieties being *flore albo pleno*, white; *flore rosco pleno*,

March or early April. The double-flowered form produces a profusion of delicate rose-coloured blossoms, each of which is well over an inch in diameter. The best results are usually obtained by cutting the flowering branches back as soon as the flowers fade. Long shoots are then formed during the summer, which the following spring bear flowers from end to end. It is useful alike for bushes in the open or for planting against walls, while it is one of the best shrubs for forcing for conservatory decoration in February. The Almonds are seen to best advantage when planted so that a background of evergreen trees is provided, as shown in the illustration on the opposite page. If silhouetted against the sky, the delicate Apple-blossom pink of their flowers is scarcely discernable. They ought not to be planted so that a house with red-brick walls forms the background, the pink blossoms clashing badly with red. W. D.

At Clandon Park, Surrey, a beautiful glade has been converted into what is aptly called the Primula Dell. The undulated woodland, with winding paths and deep, retentive soil, provides the ideal surroundings for a natural Primula garden. In May *P. rosea*, colonised by the streamside, flowers in profusion, and the same may be said of *P. denticulata*, grown in large stretches, and mingled here and there with the bright yellow flowers of the Leopard's Bane. Polyanthus in varied hues flower well, and *P. japonica* gives promise of an exceptional display. The Primulas to follow are *frondosa*, *pulverulenta*, *sikkimensis*, *bulleyana*, *capitata* and *Poissonii*. The last named is a gem at Clandon Park, and flowers well from May until the autumn. The writer will not readily forget the fine effect created by the flowering of this species in November last, when all other Primulas had long ceased to

flower. Generally speaking, Primulas are best planted after flowering, while seeds may be sown as soon as they are ripe. It is as yet a little early to speak with any degree of certainty regarding the hardiness of some of the new Primulas, but the following list is an attempt to bring together a number of new species that are destined to become great favourites, together with some of the older and better known garden Primulas.

P. beesiana.—A fragrant species introduced by Messrs. Bees of Liverpool about seven years ago. The flowers are of a purple hue with a yellow eye. It was found growing wild by Mr. G. Forrest in the moist meadows of Yunnan. Height, 2 feet to 3 feet; hardy.

P. bulleyana.—Another grand species from Western China discovered by Mr. G. Forrest. It produces whorls of rich golden yellow flowers, shading on the outside to buff apricot. It is easy to grow, and does well at Clandon Park in the shade near a running stream; it is also hardy in Scotland. When crossed with *P. beesiana* it has given rise to a race of hybrids with coppery red flowers, of which Leddy Pilrig is an example. This sturdy hybrid attains a height of 2½ feet, and the flowers are borne in seven or eight whorls to an inflorescence; the calyces are coated with farina.

P. capitata.—This species, having round heads of rich violet flowers, resembles a refined form of *P. denticulata*. It is a charming Primula for the rock garden, and will thrive as a crevice plant in partial shade, providing it can root into a moist compost of grit and loam. Unfortunately, its value is depreciated owing to its tendency to die soon after flowering. However, it seeds freely, and may easily be replenished. It flowers in June and in early autumn.

P. cockburniana.—The flowers are of a rich orange vermillion, borne in whorls on slender stems. It is short-lived, and is generally regarded as a biennial, although it is perennial in some gardens. It seeds freely, and self-sown seedlings are often produced around the parent plants. It needs a well-drained, loamy soil and a warm position, although it is hardy in Scotland. By crossing with *P. pulverulenta* some wonderful hybrids have been obtained, of which Unique and Lissadell Hybrid are best known. The variety Excelsior, with crimson scarlet flowers borne whorl upon whorl, is the result of crossing Unique with cockburniana.

P. cortusoides.—A beautiful plant, with clusters of deep rosy flowers and lobed leaves covered with a silky pubescence. It is sometimes met with in gardens under the name of Sieboldii. It is easily grown in light garden soil, but it should be sheltered from cold winds.

P. denticulata.—One of the finest of all the hardy Primulas. It is a native of the Hima'aya, and is very free flowering. At Clandon Park it is grown in stretches in shady glades, making

in May a display of unusual splendour. The heads of bloom vary in colour, but are mostly of lilac tone. The variety cashmeriana, with deep violet flowers, is worthy of special mention.

P. farinosa.—our native Bird's-eye Primrose, has small rosettes of silvery leaves and umbels of rosy lilac flowers with a conspicuous yellow eye. It is found wild on damp, grassy slopes in the northern counties of Scotland. Like many other British plants, it is no always an easy subject to cultivate. Limestone chips and old mortar rubble should be mixed with the soil.

P. frondosa.—This charming Thracian species resembles *P. farinosa* in colour and habit of growth,

poorer-coloured flowers should be annually weeded out to keep the strain as good as possible. The flowering season is from May till September. When once established in a damp position it will often increase freely from self-sown seed.

P. Juliae.—This new introduction from the Caucasus, with rosy red flowers and of Primrose habit, has created a good deal of interest. It is a moisture and shade loving plant that promises to be a great favourite when better known. It flowers in April and does not exceed 3 inches in height.

P. knuthiana.—A new hardy species recently sent home from Northern China by Mr. W.

Purdom. Its nearest ally is probably the well-known *P. frondosa*, of which it appears to be a glorified form. It is hardy and may be increased from seeds.

P. littoniana.—A distinct Primula, with flower-spikes resembling the Grape Hyacinth. It has proved hardy in Scotland when grown on well-drained loamy soil. It was collected by Mr. G. Forrest in China in 1908.

P. marginata.—Probably the best of all the alpine Primulas. It is small-growing, with leathery leaves margined with white farina, and flowers of a soft lavender colour. It is an ideal crevice plant for the rock garden.

P. Maximowiczii.—A remarkable novelty from Northern China. The drooping flowers are cardinal red in colour and borne in whorls on a stout scape rising 18 inches or so from a rosette of lanceolate leaves. It is sweetly scented and seeds freely. Moreover, it is hardy and will thrive in a similar position to *P. japonica*.

P. Poissonii.—Valuable for spring and autumn flowering. A rich, damp soil and a half-shady position suit it best. The flowers are reddish purple. In habit it is like *P. japonica*.

P. pulverulenta.—One of the best of Wilson's introductions from China. The flowers are of an exceptionally rich ruby crimson, borne on stout stems 2 feet to 3 feet in height. It seeds freely, but its white variety, Mrs. Berkeley, does not. It may be grown under similar conditions to *P. japonica*; it will also thrive in a much drier position.

P. Purdomii.—One of the most recent introductions from Western

China. The flowers are pale lilac and delightfully scented, while the foliage is densely covered with white mealy farina. It is too early to say if it can be increased from seeds, but there is every reason to hope that it will prove hardy.

P. Reidii.—A rare species of refined appearance. The drooping ivory white flowers somewhat resemble in shape those of the Soldanella. In the Edinburgh Botanic Gardens it is grown with marked success from seed sown in February or March. It does best when grown in a cold frame; if tried in the rock garden, a sheet of glass should be placed overhead to throw off excessive moisture.

A VIEW IN THE GARDENS AT PENJERRICK, NEAR FALMOUTH, CORNWALL. NOTE THE SIZE OF THE DRACÆMAS. (See page 163.)

while it needs much the same treatment as the Bird's-eye Primrose.

P. Forrestii.—A sweetly scented species, reminiscent of the fragrance of the Cowslip. It should be planted in bold masses, when the golden yellow flowers are seen to good effect. Although quite hardy, it is not an easy subject to cultivate. It has been grown successfully on dry, rocky places and on a retaining wall.

P. japonica.—This well-known Primula is indispensable for planting by the side of streams or in moist parts of the wild garden. In colour it varies from dark purple to pale rose. The

P. rosea.—This is the gem of the whole race. It is best grown near the water's edge in gritty soil. The flowers are of a brilliant rose, and the varieties *splendens* and *superba* are worthy of special note.

P. sikkimensis.—Aptly called the Himalayan Cowslip. It loves a deep, well-drained but moist soil and a shady place. The leaves disappear in winter and the plants remain dormant, but at that time they must not be molested or overlooked. Propagation is effected by division in spring or autumn, or by seed sown as soon as it is ripe.

P. Veitchii.—A hardy species belonging to the same section as *cortusoides* and *Sieboldii*.

foliage is attractive owing to its beautiful covering of white farina. C. Q.

AN INTERESTING CORNISH GARDEN.

To those unacquainted with the mild climate of the South-Western Counties of England, the gardens scattered about so freely in Devon and Cornwall, and particularly in the latter county, come as a great surprise when seen for the first time. Plants flourish there outdoors which need the protection of a greenhouse in the London and less favoured districts, with the result that the gardens always present a semi-tropical appearance. The illustration on page 162, from a photograph

Cytisus fragrans, growing beside the house and quite outdoors, produces its myriads of flowers each spring. Those who only know this plant by the small pot specimens sold in the London markets would scarcely recognise it in its shrubby form at Penjerrick. Another tree of considerable interest is *Laurelia aromatica*. This is about fifty feet high, and in all probability the best specimen of its kind in this country. It has smooth, Laurel-like leaves with dentate margins, and, when bruised, these emit a pleasant and powerful fragrance. *Magnolia Campbellii*, *Crinodendron Hookeri*, *Embothrium coccineum*, *Anopterus glandulosa*, large specimens of *Eucalyptus globulus*, *Fitzroya patagonica* and a large

BORDERS OF MIXED FLOWERS, WITH PINK MALLOWS AND OTHER ANNUALS USED FOR A TEMPORARY DISPLAY.

The numerous flowers are deep rose, and borne in umbels on erect spikes. The leaves are soft, like those of *P. mollis*. It requires plenty of leaf-mould in the soil.

P. Winteri.—An exquisite and fascinating species from the Himalaya. Although a new introduction, it is already to be seen in many gardens. It is hardy in the South of England, but it is advisable to give it protection in cold localities. The flowers are of large Primrose size, varying from pale to deep mauve. It is as profusely flowered as the Primrose, and the

taken in the gardens at Penjerrick, about three miles from Falmouth, will give readers some idea of the vegetation that thrives there. *Dracenas* and *Rhododendrons* are a great feature, the trunks of some of the former being at least 15 inches in diameter.

Mr. Robert Fox, the owner of these gardens, is a great *Rhododendron* enthusiast, and many new and beautiful varieties have been raised there. A very fine tree of *Podocarpus chilina*, 30 feet high and about 20 feet in diameter, never fails to attract the attention of visitors; and

Camphor Tree, quite 20 feet in height, are only a few of the many interesting trees and shrubs that the privileged visitor will find thriving at Penjerrick.

ANNUAL FLOWERS IN MIXED BORDERS.

THE value of annual flowers in mixed borders can scarcely be over-estimated. Without them it would be well-nigh impossible to fill the gaps caused by the passing to rest of such spring flowers

as Leopard's Bane, Daffodils and Tulips. There are two ways of using these annuals in the mixed border. One is to sow seeds of such kinds as Nemusias, Stocks, Asters and Antirrhums in frames and subsequently plant the sturdy seedlings where they are to flower; and the other, to sow the seeds of the more hardy kinds during April wherever they are needed to grow and blossom. Thus at the present time seeds of Clarkias, Godetias, Leptosiphon, Pot Marigolds, Cornflowers, Pink Mallows, Larkspurs, Nigella, Night-scented Stock, annual Chrysanthemum, Candytuft, the fragrant Mignonette and, a few weeks later, the dwarf Nasturtiums may well be sown between the bulbs named, or, indeed, between almost any early flowering plants that find a more or less permanent home in the mixed border. In the portion of border shown on the right of the illustration on page 163, the charming Pink Mallows have been successfully used, and add charm and colour where otherwise annoying blank spaces would have existed.

TULIP AND DAFFODIL NOTES.

BY THE REV. JOSEPH JACOB.

Forced Darwin Tulips in Holland.—

Readers are doubtless well aware that within the last few years it has been found that certain varieties of Darwin Tulips with appropriate treatment can be had in flower very early, not perhaps at the same time as those dwarfier kinds which have always gone by that name, but long before we would have thought it possible in the first days of their introduction. William Copland may be cited as the most striking example of what can be done in this respect. Messrs. James Carter and Co. startled us in January of last year by showing some vases of a pretty, long-stemmed lavender Tulip labelled Sweet Lavender. It appeared again in February and, if my memory serves me, also in March; but each time the blue tone seemed less pronounced and a redder one began to predominate. Those "in the know" were well aware that Sweet Lavender was but William Copland garmented in the fine linen of those who live in glass houses. The heat and the glass had brought about a wonderful transformation, for, outside, William Copland was one of the old Darwins that were only hanging on by their eyelids.

Experiments on a large scale took place in Holland both in the winter of 1913-14 and in that of 1914-15. Thanks to Messrs. de Graaff Brothers of Leiden and to Messrs. E. H. Krelage and Son of Haarlem, I am in possession of the results of some of the above-mentioned trials. About a month ago I had two letters from my friend, the head of the latter firm, giving an account of what happened in his case in this last season. The contents are so very interesting and instructive that I feel sure many readers will like to know what they were, and as I have Mr. Krelage's permission to make any use I like of his letters, "here goes."

One of the prominent fixtures of the Dutch Bulb Growers' Association is their "prepared" Hyacinth exhibition, which last year (1914) was

held on December 23. An attempt was made to have some Darwins in bloom then, but it was a failure. During January the firm obtained some excellent flowers, "but the first practical results of high-grade faultless blooms without failures" were produced in mid-February. On the 15th of that month the following were shown: Anton Mauve, Charles H. Marot, Crépuscule, Duchess of Hohenberg, Fra Angelico, Frans Ha's, Giant, Harry Veitch, Leonardo da Vinci, Othello, Red King, Wally Moes and William Pitt.

On the 22nd, a week later, forty-seven varieties were exhibited, viz., those mentioned above and the following additional ones: Ariadne, Calypso, Centenaire, Electra, Eugène Delacroix, Feu

Gudon, Jacob Maris, King George V., Queen Emma, Mme. Banois, Madrazza, Millet, Mr. Farncombe Sanders, Mrs. Cleveland, Mrs. Potter Palmer, Niobe, Nora Ware, North Dakotah, Oregon, Ouida, Paris, Parthenope, Pomona, President Taft, Princess Mary, Princess Elizabeth, Prince of the Netherlands, Prince Eugen, Remembrance, Sir Trevor Lawrence, Thérèse Schwartz, The International, Vitellius and Weber. So on February 28 last eighty-five varieties were on view at one time, each one in excellent condition, with firm, straight stems.

Mr. Krelage says at the end of his second letter: "It is a pity you cannot come and inspect them personally, but such excursions cannot be recom-

mended for the moment." Well, I hope this war will not go on for ever. Another year perhaps there will be no hostile submarines in the North Sea, and then it would be very pleasant to have an invitation. Possibly other Tulip people might like to come, too. Some of them already have heard of the Trianon at Amsterdam!

In Vincent Square only one Darwin exhibit was staged up to the end of March. On the 16th Messrs. Waterer, Sons and Crisp put up a small collection of sixteen varieties, together with a few Cottage sorts. The stems were rather weak, and this defect was not minimised by the somewhat bald arrangement of the group. The list of varieties is interesting when compared with the Dutch ones: Admiral Togo, Edmée, King Harold, Marconi, Margaret, Mrs. Potter Palmer, Mr. Farncombe Sanders, Nora Ware, Psyche, Rev. H. Ewbank, Salmon King, Sweet Lavender, The Sultan, Suzon, Tak van Poortvliet and Velvet King.

One often has to go away from home to hear the news. In the *Revue Horticole* of Paris for March 16 (which paper, by the way, I am heartily glad to see getting into its stride again after its temporary absence from the track) there is a list of some of the early Tulips shown at Haarlem on December 23 last. By the side of the Duc van Thols and Proserpines were Fred Moore, Mrs. Elwes, King of the Yellows, Mon Tresor, van Schalken, Le Matelas, Vesuvius, Rembrandt, Brilliant Star and Lady Borell; and in doubles, Toreador, Couronne d'Or and Salvator Rosa.

Royal Horticultural Society's "Daffodil Year Book."—"To be or not to be" has been the question. The Council have, however, finally decided that it is to be in 1915 "as usual." I am again to be its godfather. I have one or two special wants in connection therewith—first, a

good likeness of the late Rev. G. P. Haydon; and, secondly, any number of short paragraphs of from six to ten lines of print on small matters or incidents that would be of general interest to the fancy. I made a similar request last year, but I regret I had no response. A chapter of odds and ends would make interesting reading; so, readers, please think of the Year Book when any chickens are hatched.

Daffodil White Lady.—Many people are of opinion that the name of Engleheart will go down to posterity coupled with this variety more than any other. It is a splendid all-round flower, and worthy to rank beside Emperor and Barrii conspicuously. I believe it is now exactly twenty-one years

THE NEW SILVER "BARR" CUP FOR DAFFODILS.
(See page 165.)

Brilliant, General de Cordous, Glory, Gretchen, Gryphus, Jhr. Schorer, La Fiancée, La Tristesse, La Tulipe Noire, Lioba, Mme. Virnot, Mauve Clair, Minister Röell, Miranda, Mystery, P. de Commynes, Prince of Wales, Raphael, Salmonea, Sierrad van Flora, Suzon, The Sultan, Venus, Vespuccio, Viola, W. A. Viruly Verbrugge, Whistler, Zephyr and Zulu.

There was no committee at Haarlem on March 1, but on February 28 Messrs. Krelage and Son had a private view in one of their warehouses, where these additional thirty-eight sorts were on view: Aïda, Bartigon, Blushing Bride, Clara Butt, Claude Monet, Dante, Edmée, Etna, Europe,

since it was introduced to the public, and it is still going strong. My congratulations to her raiser on her coming of age, *but* it is another milestone past.

[Regarding the early Darwin Tulips mentioned by Mr. Jacob, from what he tells us it is only those who can give sufficient bottom and top heat who can hope to have them in good condition so very early.—ED.]

A NEW CUP FOR DAFFODILS.

THE illustration on page 164 represents the silver cup, value 7 guineas, that Messrs. Barr and Sons are offering at the following shows this year, one cup to go to each show: The Royal Horticultural Society's Show at Vincent Square on the 13th and 14th inst.; the Hereford Spring Flower Society's Show on the 14th inst.; and the Midland Daffodil Society's Exhibition on the 21st and 22nd inst. The design of this cup is excellent, the Daffodils, shown in relief, being well executed.

SOME BULBS FOR SPRING PLANTING.

IN a great many country gardens there is a demand for plants that flower in early autumn, and although there is a goodly host of herbaceous kinds that naturally flower at that season, those with bulbous or tuberous roots are more or less neglected. If we eliminate the Montbretias, Gladioli and late-flowering Lilies such as *speciosum*, very few of the kinds that can be, and often are best, planted in spring will be found in most gardens. One cannot help thinking that this is a mistake. Montbretias and Gladioli, to which reference has already been made, are too well known to need extended comment; it will suffice to remind those who would grow them that the end of March or early in April is a good time for planting. There are many beautiful varieties in each family, particulars of which can be obtained from any bulb catalogue, and they ought not to be placed directly in contact with raw manure at the time of planting. Those who appreciate blue flowers in autumn should get the varieties Blue Jay and Baron von Hulot, which are the best Gladioli of this colour. One of the best bulbous flowers to put in just now is *Hyacinthus* or *Galtonia candicans*. The bulbs can be purchased quite cheaply, and should be placed from 4 inches to 6 inches below the surface. If the soil is mainly clay, it is advisable to spread some sharp sand under and around the bulbs, and this applies to most other kinds mentioned. *Hyacinthus candicans* attains a height of 4 feet to 6 feet, and the upper portion of the flower-stem is bespangled with glistening white, bell-shaped blossoms. Massed in an open spot in the shrub border, in the herbaceous border, or in beds of Azaleas or other spring-flowering shrubs, this plant is very effective, and it is equally good for cutting.

The Peruvian Lilies, or *Alstroemerias*, are bulbous flowers that we see too little of. It is true that they are not well adapted for very cold soils or situations, but in all moderately warm gardens such kinds as *chilensis* and *aurantiaca*, with their several variations, will give a good return in the way of curious-shaped and wonderfully mottled flowers. The bulbous roots need to be planted at least 9 inches deep and sanded around as advised for *Hyacinthus*. In warmer districts *Alstroemeria pelegina*, a very beautiful species, may be grown. The *Belladonna Lily*, with its large, rose pink

flowers, is always greatly admired when seen in flower, and spring is a suitable time for planting the bulbs. These need to be placed at least 9 inches below the surface, and must be accommodated under the south wall of a warm greenhouse. When visiting Carrow Abbey during the autumn of 1912, I saw a fine display of this noble plant in a narrow border under the wall of one of the plant-houses, and the dainty little *Zephyranthes candida* was used as an edging. This is a low-growing bulbous plant with dark green leaves and fairy-like white flowers, and the effect created by the *Belladonna Lilies* and these was very charming. As the *Zephyranthes* can also be planted now, those who have suitable borders may care to arrange for a similar effect next autumn. I ought to mention, however, that the *Belladonna Lily* does not usually flower well the first year it is planted.

Although the corms of most hardy *Cyclamen* are planted in autumn, there are two which may be put in now, viz., *C. neapolitanum* and *C. europæum*. The former has rosy pink or white flowers, and the latter, dainty little blossoms of crimson purple hue. Both flower in autumn, appreciate overhead shade, and some old mortar or similar lime containing material in the soil. Two inches is quite deep enough to plant these. *Ranunculuses*, at one time the treasures of many of our best gardens, are seldom seen nowadays, yet they embrace such vivid Oriental colours as we get in few other autumn flowers. The grotesque-looking roots are best planted in March or early April, in an open spot towards the front of the border, and if some well-decayed cow-manure can be mixed with the soil, the plants will greatly appreciate its cool and nourishing properties. Poppy *Anemones* may also be planted at this season where late flowers are desired, although many prefer to consign them to the earth in autumn for an early summer display. For a sunny bed or border, and where the soil is well drained but of a nourishing character, a few at least of the *Tigridias* ought to find a place. They have gorgeous flowers of many bizarre hues, those in which yellow predominates being, perhaps, the most effective of all. The bulbs ought to be planted about three inches deep early in April, and lifted again after all the leaves have faded. H.

NOTES ON VEGETABLES.

THE month of April is an exceptionally busy time in the kitchen garden; any delay in sowing or giving the necessary details of culture, such as thinning the surplus plants of Carrots and Parsnips, means a much impoverished crop.

Keeping the soil stirred, too, among growing crops is a most important item in accelerating the growth, hence under no circumstances should this detail be neglected. The staking of Peas is another point meriting prompt attention. If the haulm is allowed to fall on one side for the want of support, the growth afterwards is crippled. An early earthing up of the plants when 6 inches high does much to support the haulm at the base.

Broad Beans.—Make the last sowing in the open of either a Longpod or a Windsor variety, allowing rather less space than at the previous sowings, as the plants are not quite so robust in growth as those from seeds sown earlier. Those raised in boxes should be planted out in double rows, as usual, allowing 10 inches between the rows and 9 inches between the plants; 2 feet 6 inches from one double row to another will suffice.

Broccoli, Cauliflowers, Leeks and the various Kalcs and winter greens should be sown in the open on a piece of well-prepared ground. If the soil is dug at the time of sowing, well soak it the day previous, which is much better than watering the seed-beds afterwards. Break the soil quite fine on the surface and sow the seed thinly to avoid overcrowding of the plants, which is fatal to ultimate success. After lightly covering the seed, sprinkle the surface with wood-ashes, which are a preventive of attacks by Turnip fly. Protect the beds with netting to prevent birds pulling up the tiny seedlings, which they are apt to do when peeping through the soil.

Cardoons.—The growing of this vegetable is not nearly as common as its merits deserve, and especially when we consider how easy the plants are to produce. Prepare a trench as for Celery and sow the seed thinly in a drill in the centre, thinning the plants to one in a space of 2 feet when large enough to handle.

Carrots.—Now is a good time to sow the main crop. Of all vegetables, none pays better than this for a thorough preparation of the soil, especially if it is stiff and contains many stones. Without free access for the tap root, Carrots cannot be shapely and large. A few days previous to sowing, deeply fork over the ground, thoroughly breaking the clods. Rake the surface fine, and sow thinly in drills 15 inches apart for the large-growing sorts like New Red Intermediate or Long Red Surrey. Shorter sorts may have 3 inches less space. Cover the seed with wood-ashes, raking down the surface smoothly and covering the wood-ashes with the soil from the drills.

Brussels Sprouts.—The plants from the early sown batch will now be ready for putting out into their permanent site, lifting each carefully with a ball of earth attached to the roots. Plant in rows 2 feet 6 inches apart and allow 2 feet between the plants. Where space can be afforded, a yard apart is none too much, especially where the soil has been heavily manured. If the plants are still in the seed boxes or pans, transplant them into a cold frame or other boxes in a light compost, and hasten on the growth by keeping the frame closer for a week or two. The stouter the plants are when put in the open, the better is the prospect of success.

Lettuce Plants wintered thickly in cold frames can now be put out on a warm border, covering the soil about each plant with finely sifted coal-ashes as a deterrent to slugs, which are partial to the succulent leaves.

Asparagus-Beds should now have attention. Keep them free from weeds, and lightly and carefully fork over the surface 2 inches deep if the soil is inclined to be of a close, retentive character. Afterwards give a dressing of common salt at the rate of 3oz. to the square yard. Last year's sown or planted beds can be much improved in growth if the plants are well saturated with liquid manure or sewage water during the months of May and June. In newly planted beds the point is to induce the plants to make as much growth as possible, and instead of cutting any stems, allow all to grow and mature for the first two years. Some support should be given to the stout growths to prevent their being blown about and often broken, which is detrimental to success. Short, bushy Pea stakes thrust into the soil among the plants answer capitally. Failing these, a wire should be stretched along the rows 2 feet high, to which the stouter growths can be secured.

Swanmore, Hants.

E. MOLYNEUX.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Strawberries in Pots.—Strict attention must now be given to Strawberry plants growing under glass. It is almost impossible to give them too much water at the roots, and the plants which are swelling their fruits will require liberal applications of stimulants till the fruits begin to colour. The foliage also must be vigorously syringed two or three times a day. Plants growing in Peach-houses or vineries should be moved to a cooler house when the berries are ripening. The plants which are still in their winter quarters must be examined regularly to see if they need water, giving them an occasional dose of manure-water.

Cherries in Pots.—When the fruits have set, the trees will require some form of stimulant, but they must not be overdone in this respect till growth is more active. Do not attempt to force the swelling of the fruits, especially by artificial means. Admit plenty of air during favourable weather, using both top and bottom ventilators, and leave them slightly open during the night. Look out for the small grub, which will be found curled up in the leaves.

Early Pot Vines.—When the berries commence to colour, the atmosphere must be kept less moist and more air should be admitted, leaving the top ventilators open a little during the night. The roots must still be liberally supplied with water, but manures should be gradually withheld as the berries approach ripeness. The temperature must still be well maintained, but excess of fire-heat should be avoided while the Grapes are ripening.

Plants Under Glass.

Pot Roses.—As the earliest plants pass out of flower, they may be removed to a sheltered position outdoors. The climbing varieties can now be forced gently into growth. These will be well rooted, and must be well supplied with stimulants, or the colour of the flowers will be poor. Ventilate the houses carefully when cold winds prevail, or mildew will quickly spread.

Sweet Peas in Pots.—Plants which are showing their flower-buds will require abundance of water. Liquid manure and some approved fertiliser must also be given frequently. Keep them growing in a cool, airy house, and when in flower shade them from bright sunshine.

Bouvardias.—Move the young plants into 3-inch pots when large enough. Give them a position near the glass in a moderately warm house. The shoots will require stopping two or three times to encourage a bushy habit. When the plants have been transferred to their flowering pots, they must be gradually hardened off, eventually plunging them in ashes in a cold frame.

Pelargoniums.—The plants which are being grown for flowering in the autumn and winter must have their tops pinched out. A position on a shelf in a cool house will suit them till they are placed outdoors. The fancy kinds must be carefully staked. When these are showing their flower-buds, they should be liberally supplied with stimulants.

The Flower Garden.

Forced Bulbs.—Many Tulips and Narcissi which have been grown in pots may be planted next autumn in the wild garden. In the meantime they can be placed close together in a sheltered position and kept supplied with water till the foliage has died down. Astilbes which have been forced may also be made use of for planting by the margins of streams or ponds.

Bamboos.—Large clumps of Bamboos may be improved by a judicious thinning of the growths. This work can be done now, before the young shoots have made much progress. The present month will be suitable for replanting Bamboos. The ground must be thoroughly prepared by deep digging and manuring, and the work of replanting should not be done till the soil is in a suitable condition.

The Hardy Fruit Garden.

Peaches and Nectarines.—Disbudding of these may be commenced as soon as the shoots are large enough to handle. At the first operation about half the shoots can be removed. Commence

at the top of the trees, and bear in mind to leave a well-placed shoot as near to the base of this year's fruiting wood as possible. When the final disbudding is completed, there should be one growth at the base and one at the point of the shoot, unless it is necessary to leave more to take the place of old, worn-out branches next season. The final disbudding of young, vigorous trees should not be done quite so early as the old-established ones.

Apricots.—Where the fruits have set thickly, some of those which are badly placed may be removed at once. The general thinning of the fruits must not be done till it can be seen which are going to swell. Some of the surplus growths may now be removed, but make sure that sufficient are left to form spurs. These will require to be pinched when they have made several leaves. Where there is room to lay in a young growth, one should be left for this purpose.

The Kitchen Garden.

Potatoes in Frames.—Plenty of air must be admitted to the frames, or the haulm will become drawn and weak. On favourable days the lights may be entirely removed. Cover the glass with mats at night when frost is imminent.

Cauliflowers.—The earliest plants in pots will soon be ready for planting out. Remove the lights whenever the weather will allow, so that the Cauliflowers may be thoroughly hardened off before planting them out. A well-cultivated piece of ground in a sheltered situation ought to be selected for their reception. Should the weather be dry after planting, they must be regularly supplied with water.

Seakale.—The thongs which have been prepared for planting will now be ready for the open. Plant them in rows 2 feet apart, allowing 1 foot between the plants. The sets must be buried about an inch or so beneath the ground.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Cyclamen.—As the plants pass out of flower, water should be gradually withheld. A sudden stoppage of moisture would injure the corms for another season. Stand the plants on an ash-bed in a cold frame and ventilate freely.

Clerodendron fallax must be potted on as the plants develop. Use a fairly rich compost for this potting and keep the plants growing in a very humid, warm atmosphere. The syringe should be used unceasingly to keep red spider in check.

Gesneras.—Some of these may be started to keep up the display in the flower-house. Start in the stove in a light compost in which there is plenty of peat, leaf-soil and sand.

Tree Carnations.—With the lengthening days and greater sun power the quality of the blooms is greatly improved. Still endeavour to maintain a night temperature of 50° to 55°, keeping the atmosphere as buoyant as possible. After this date very little artificial heat will be required, unless on very damp and cold nights. Young plants must be attended to promptly in the matter of potting on and pinching out the tops, keeping them as long as possible on a shelf near the glass. On bright days the staging and pathways may be damped down.

Chironia ixifera.—This useful decorative plant is easily propagated from cuttings if they are put in now in a warm propagating-case. To succeed well the plants must not be overpotted, and should be watered with care. An intermediate temperature suits them best.

The Flower Garden.

Montbretias.—As these are now commencing to grow vigorously, it is time to plant out. The ground having been previously prepared for their reception, the planting simply consists of taking out small trenches and laying in the corms very carefully with the stolons attached, but not at all deep. If planted in rows, they should be 15 inches apart.

Asters.—For the general summer display the sowing of these annuals ought not to be further delayed. Sow thinly in boxes and place in very gentle heat, when they will quickly germinate.

Stocks.—Seeds of Ten-week and Beauty of Nice type should now be sown. As soon as germination has taken place, grow under cool conditions. Watering must be done very carefully, as the seedlings are liable to damp off.

Lawns.—Any portions requiring renovating and levelling must be attended to. This is a good season to sow lawn grass seed, as it then has time to become established before the summer.

Tuberous Begonias.—If these are not already started, they should now all be placed in boxes of leaf-soil and put in gentle heat. Very little moisture will be required except an occasional syringing until the plants are growing freely.

Fruit Under Glass.

Orchard-House.—The majority of the fruit trees will be in bloom, and should be regularly fertilised about the middle of the day. When it is seen that the flowers have set, a judicious thinning of the fruits ought to take place, so as not to overtax the energies of the trees. As it is particularly difficult to prevent some varieties of Pears and Plums from dropping their fruit, great care is required in their treatment, especially regarding ventilation and the application of water.

Early Figs in pots should have a top-dressing applied, as surface roots are very active. Good loam with a fair proportion of some fertiliser which can be quickly assimilated is best, and, for some time after, watering should be done through a rose. If the crop of fruit is rather heavy, it will be an advantage to slightly reduce it.

Early Vines.—Now that the berries are swelling, some extra help may be given to the Vines by an application of liquid manure. The strength should be reduced sufficiently to allow it to be applied without fear of injuring the Vines. If the liquid is very rich in ammonia, it will be as well to leave a small amount of air on the top of the vinery until the fumes have escaped.

The Kitchen Garden.

Celery.—The trenches which are to be occupied later by the Celery crop should now be made before the ground becomes any drier. If there is not much depth of soil, it will be better not to make deep trenches, as these would not leave sufficient soil for the plants to flourish in. Within reason, it is almost impossible to grow Celery too large for general use; therefore the trenches must be treated to a very liberal dressing of cow-manure.

Leeks for general use should be now sown. The plants will be available for filling up ground which has been occupied by some early crop.

Potatoes.—The early crop must be planted in a warm, sheltered border. Do not plant with a dibble, but take out small trenches with a spade, so as not to break any of the tender young shoots. As the young growths appear through the ground they should be constantly covered with soil as long as possible.

Asparagus.—All loose top-dressing, such as Seaweed or litter, must now be cleared off, and the beds and paths between raked over. This is a good time to apply a reliable Asparagus manure.

Peas.—Further sowings of midseason varieties should be made whenever the condition of the soil will allow. As the earlier ones grow, some soil ought to be drawn into a small ridge along each line. Protect with small twigs of Spruce until ready for staking.

Brussels Sprouts.—Do not delay having all that are ready pricked out in cold frames, where they can remain until the end of the present month. As soon as the check of removal has been overcome, admit air freely.

Radishes.—To succeed the crops in frames or on hot-beds an outdoor sowing should be made. For general use French Breakfast is a most desirable variety. Do not sow too thickly, or a number of the seedlings may refuse to develop. This vegetable must be used when young and tender.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

CREAM PINK SWEET PEAS

THIS is by far the largest section, and there have been quite fifty names used since Mrs. Henry Bell was first introduced. It is quite evident that it is a popular section, as so many raisers and others have been striving to get the ideal cream pink. I see the National Sweet Pea Society has divided them into grades. This is a step in the right direction, and will be greatly appreciated by small growers. I hope the society will go a step further and give the names of the best varieties in each section for garden and exhibition. No other cream pink variety impressed me so much as Duplex Spencer at the National Sweet Pea Society's show in July last. It was only shown eight times, but I see it was in five first prize stands. When I stood in front of a grand vase of Duplex Spencer from Ruabon, nearly all double standards, I began to think of the twaddle that was written about double standards only a short time ago. Most of the critics were excused then, as they had never grown Sweet Peas strong enough to carry any more than single standards. Duplex Spencer is an ideal Sweet Pea for the garden as well as for exhibition.

There are two new varieties I am growing this year to compare, viz., Duchess of Portland and Helen C. Stapleton. In the deep cream pinks there are Mrs. R. Hallam, Lancashire and Hawmark Ladys. The latter as shown by Mr. E. Cowdy was grand. The colour is like that of Mrs. Hallam, but it is a larger and bolder flower. Mrs. Hallam is a grand decorative and garden variety. Lilian is, perhaps, a larger Sweet Pea than either in this section, but is rather soft, and with me has not been quite fixed. I hear rumours of Syeira Lee fixed in Duplex form. May it come soon!

T. B. L.

UNDESIRABLE PLANTS IN THE ROCK GARDEN.

AS I am keenly interested in the discussion on this subject initiated by "E. H. J."—whose initials barely hide his identity—and followed up by Sir Archibald Buchan-Hepburn, I ask to be allowed to make the following remarks.

I am inclined to demur to the condemnation of all the plants named, as under certain conditions they can almost all be utilised. But as there are so many different kinds of rock garden, I will try, if I may, to describe one which is my particular care. It is a low retaining wall 4 feet high, about fifteen inches thick, built of the yellowish red ironstone of the country where I live, formerly cottage walls. It was at first a dry wall running round three sides of my bowling green, an aggregate length of about one hundred and thirty yards, the top of the wall being on a level with a terrace. The coping having been removed, a quantity of light, loamy soil was placed on the top of the wall, and in this at first were planted a lot of suitable and unsuitable plants, such as Aubrietias, Sedums, Wallflowers, Mossy and Encrusted Saxifrages, Helianthemums, Spiræas, Aquilegias, Nepeta Mussinii, Cerastiums, Linaria hepaticæ-folia, Veronicas and many others.

Needless to say, many of these died, succumbing to the law of the survival of the fittest and a very dry summer which followed the building of the wall. As it was my ambition—a belated one, I admit—to get plants to grow on the face of my wall, I set to work to fill every interstice with soil, a task which occupied me for many months, and necessitated as many tools as a dentist employs in his profession; but from time to time I kept inserting bits of the very commonest things, such as Sedum acre, Sempervivum tectorum, Cinquefoil, wild Strawberry, Violets, Foxgloves, even common Yarrow, and with iron rods, bits of wire and a watering can I coaxed the soil on the top to percolate down, always keeping a good supply to take its place—a good mixture of loam, peat, sand, granite and limestone chips and grit. It was a slow business, but it gradually succeeded. I think my thanks are due in a measure to lob and other worms, which carried down to inaccessible places and crevices what was food for my plants.

My wall in course of time became fairly well populated or clothed. I never heeded the remonstrances of the fastidious at having such common things on my wall. My invariable reply was that as soon as I got anything better to put in their place, out they would go. I found Foxgloves thrive exceedingly well and flowered abundantly, to everybody else's disgust. Judge of my feelings one morning to find every Foxglove plant torn out by the roots, the loving work of an indignant inhabitant of my house; but I plodded on undismayed by incidents like this, and my wall is now what I would not be ashamed to show to anyone who is a judge or a lover of rock plants. Many of my plants, I grant, are common, others are rare, some quite unknown, but almost every plant has its associations.

I have a quantity of Saxifrages which I brought back with me from the granite cliffs on the fjords of Norway. There is a beautiful road with a wall on each side between Menaggio and Caddenabia on Lake Como, which some readers of THE GARDEN will remember. I have several tokens of a delightful holiday from there and the hills around. I have a Primrose from the churchyard of Hughenden; I have a Violet and wild Strawberry from that quiet spot Jordans, where the great William Penn sleeps, and which is the Mecca of the Quaker community. I have a lovely little Dianthus, a cutting from plants growing in profusion at the foot of a monument at Daylesford, underneath which lies the great Pro-Consul Warren Hastings. He was born and brought up at Daylesford and attended the village school close by.

I have a friend and schoolfellow who is now a professor of mineralogy, whose profession and zeal carries him into remote and untrodden spots in Switzerland and the Tyrol where no tourist is ever seen. Bearing me in mind, he picks up by the roots, with a little earth, beautiful little treasures whose names I do not know and no one can tell me. These with Anemones, Dianthi, Globularias, Geums and Silenes are in perfect health and vigour on my wall. My friend wraps them up in a few folds of tissue paper, packs them in a small cardboard box, and addresses and posts it in the ordinary way. It arrives in two or three days. I plunge the contents into a bowl of rain-water. In twenty-four hours every plant is as fresh as if unearthed yesterday.

Also I have friends sympathetic and kind living at the foot of the Cordilleras, also among the Andes. These occasionally, as opportunities

offer, send contributions to my museum. Though I do possess specimens from the Ural Mountains, the Caucasus and even the Himalayas, these, I am afraid, I have been extravagant enough to purchase. I spent six weeks last summer in Wharfedale in the West Riding. I found the fells a mine of wealth to the rock gardener—any quantity of *Primula frondosa*, *Pinguicula vulgaris*, &c. I was informed by an alpine botanist, though I do not pretend to be an authority myself, that there are few alpine plants which cannot be found on the fells. Under some physical difficulties I was able to secure a good many specimens. While I was ransacking the fells, I was fortunate enough to have a friend staying at an out-of-the-way village in Switzerland, who was able to send me by post in cardboard boxes quantities of plants every few days culled from those famous alpine meadows. These upon arrival were plunged into damp sand and peat to await my return, and are all doing well in their new habitat. They were the last spoils secured before the curtain of war fell upon us all, rock gardeners included.

I do not wish it to be inferred that all these plants are in my wall. No, no; I have another rock garden on a very modest scale situated on the border of a small stream, where there is a moraine constructed on the most approved plans, so far as we have learned them from experts, who are not quite in accord with each other; but we are humble students, and read the masters like Messrs. Robinson, Wright, and Clarence Elliott, and that fascinating little book of Mr. Malby's. There are many others.

We have also established a bog, and on a kind of miniature range of limestone rocks with every necessary aspect we try to humour the idiosyncrasies of our plants, so far as we can discover what they are in the face of contradictory opinions of our experts and masters. Near at hand we keep heaps of black peat, sharp sand, limestone and granite chips, or grit. Of loam of a good light kind we have an abundance, and this has plenty of lime. What more can they or we require? Now, after relating all this at such tedious length, "E. H. J." and Sir Archibald will, I hope, understand that a good many of their undesirables, while I admit they are most objectionable on account of their rampageous habits in the ordinary well-conducted rock garden, can be used with great success and effect in the chinks of a retaining stone wall filled in or stuffed as I have described mine.

Now, with all due respect and diffidence, I consider Sir Archibald's list much too sweeping, and I would make an earnest appeal on behalf of the *Acænas*—I have at least four varieties which suit my wall, especially *microphylla* and *Buchananii*; also on behalf of *Linaria hepaticæ-folia*, which, though most objectionable on the grounds and conditions stated, is an admirable little plant on the face of a retaining wall with its tiny, modest white Violet flower and mottled leaf. *Cotula squalida* is another excellent plant in a chink. I find, however, the following—though each is beautiful in its way—very troublesome: *Vinca minor alba* and *Convolvulus althæoides*, both of which, even on a wall, require the constant application of a strong pair of scissors to cut them back to prevent them throttling their neighbours. *Oxalis corniculata* is also a pest, I agree, and should be grubbed up with a small fork as soon as seen. It is easily detected.

As my contribution to the list of undesirables not yet listed, may I place *Corydalis lutea*, the

most persistent of succulent plants, which seeds itself everywhere, quite indifferent to any conditions of hardship. I would also like to veto a certain number of Dianthi, unnamed varieties, sent to me from the Pyrenees, great straggling things with very little bloom in proportion to the vegetation and room they occupy. I have uprooted a quantity of these, reserving *cæsius*, *deltoides* and *neglectus*.

Double *Arabis* is also, I think, undesirable and untidy, though a persistent bloomer. I agree with "E. H. J." and Sir Archibald about *Cerasium*, but I had anticipated the plan of curbing their irrepressible roots by stuffing them into an old half-pound Tobacco tin with a hole knocked in the bottom for drainage, and burying them up to the neck. This has answered with *tomentosum*, but with *Biebersteinii* still more drastic measures must be taken. I must, however, to give this German devil his due, be grateful for his beautiful green cushions during the winter months, which add to the appearance of my wall. I did not know that earthenware cylinders could be purchased and used for the purpose Sir Archibald describes. I wonder where he gets them!

In conclusion, may I give a list of plants in flower on the top and on the face of my wall on March 15: *Aconite* (common), *Arabis* (single), *Hepatica angulosa*, *Crocus* and *Snowdrops*, *Iberis* Little Gem (just coming on), *Anemone blanda* in various shades of blue, *A. fulgens* (just bursting into bloom), *Aubrietia* Lloyd-Edwards and several other varieties, *Myosotis* (common), *Narcissus cyclamineus*, *N. minimus*, *Iris Danfordiæ*, *Primulas* and *Polyanthuses* in great variety, *Primula marginata*, *Saxifragas sancta*, *Elizabethæ*, *Faldonside*, *oppositifolia*, red and white *burseriana*, *Boydii* and *apiculata*, *Soldanella alpina*, *Scilla sibirica* (at foot of wall), and *Phlox subulata* G. F. Wilson.

EDWARD BROWNE.

Grey Court, Astrop, Banbury.

NYMPHÆA GIGANTEA A TRAP FOR BEES.

ONE would hardly suppose that the blue flowers of this splendid aquatic could become traps for the destruction of honey bees, in some localities in hundreds or thousands, but such is a fact, and I will endeavour to explain this curious matter. This *Nymphæa* abounds in many of the fresh-water creeks which flow into some of the north coastal rivers of New South Wales, as well as in lagoons and billabongs in the dry parts of the country to the north-west. The fresh-water creeks to which I refer are tidal, the water being backed up by the inflowing tides from the ocean many miles distant, and although the Water Lily flowers stand well above the water—1 foot or 18 inches—at low tide, they are completely submerged at high water. As the tide rises the flowers close very tightly, and as the water recedes they open again uninjured. When the flowers are open, they are visited by vast numbers of bees, and numbers of these bees remain busy collecting their requirements, and the gradual closing of the flowers is evidently unnoticed by them when the tide rises. By the time the blooms expand again, all the bees are dead. When I first noticed numbers and numbers of dead bees in the flowers, I was puzzled to account for the destruction, and imagined that the flowers might be poisonous, although I had seen thousands of other bees buzzing around and leaving the flowers apparently unaffected; but at last I discovered

the reason by later observations. Although the honey bee, the common European bee, has existed in the vicinity of this trap for at least fifty or sixty years, it has not yet discovered how to avoid the danger. Whether our native bee, a stingless species about the size of a house-fly, ever visits these flowers I cannot determine, but I have never detected a dead one there. He may have learnt the secret, or he may avoid the flowers to keep clear of his larger brother. When seen in their native glory the flowers of *Nymphæa gigantea* are extremely beautiful, thousands of them sometimes standing well above the water and their handsome, large leaves. The plant seems to thrive best in rather deep water—8 feet to 10 feet deep—and in such places it is very curious to see from a boat enormous numbers of new but undeveloped leaves rising out of the mud below, having the appearance of whip snakes. This illusion is heightened by the appearance every now and then of a real snake gliding over the water or the large, circular leaves of the Water Lilies.

WALTER S. CAMPBELL.

Vamluse Road, Rose Bay, Sydney, New South Wales.

SOME ROSE NOTES FROM NEW ZEALAND.

THE article by "Somerset" in THE GARDEN for October 31, 1914, will, no doubt, bring forth many replies, as varied as they will be interesting. He strikes the keynote when he says he does not want to "spray once a fortnight." There are many more in the same street. They have neither time nor energy. The trouble about mildew is that though we stop it on some shoots, those that grow afterwards will be just as bad, and spraying will have to be done over again. It is of no good going into the reasons; the fact remains that we have it always with us. The freest Roses with me are Mme. Jean Dupuy, Maman Cochet, White Maman Cochet, A. R. Goodwin, General Macarthur, Melody, Mrs. Dudley Cross, Earl of Warwick, Mme. A. Chatenay, General Gallieni and Zephyrine Drouhin. The wichuriana section are bad in some seasons, with the exception of American Pillar and Alberic Barbier. Climbing Roses seem to suffer considerably, and, as far as I know, W. A. Richardson and the Yellow and White Banksians are the best. While giving these Roses that are free or fairly free, there are some that do not get it badly, notably Lady Hillingdon, Mrs. H. Stevens, Louise Catherine Breslau, Theresa, Laurent Carle, Ulrich Brunner, Tom Wood, A. H. Gray, Hugh Dickson, Lady Alice Stanley, Rayon d'Or, Mrs. Cornwallis West, W. E. Lippiatt and British Queen. The worst that I know are Killarney and its white sport, Frau Karl Druschki, Commander Jules Gravereaux, Mrs. John Laing, Mrs. R. G. Sharman Crawford, Grüss an Sangerhausen, Irish Elegance, His Majesty, George Dickson, J. B. Clark, Countess of Gosford, Jonkheer J. L. Mock and William Shean among the dwarfs. Climbing *Devoniensis*, Souvenir de Mme. Leonie Viennot (the best of all climbers), Climbing Caroline Testout, Mme. Jules Gravereaux and Crimson Rambler would get white with it if it was not checked. Climbing White Maman Cochet, about the most rampant grower I know, is, like its dwarf parent, entirely free. This has not been a good season in this part of the world for Roses, as it has been exceptionally windy. In the words of the oldest inhabitant, "The worst I have ever known."

The early spring was very dry, and Roses did not get a good start in life. Most of the shows were held as usual, but the blooms were not as good as they generally are. Only one or two good blooms of George Dickson were staged. Perhaps the best was Melody; it seemed to revel in the dry weather. The second crop is now in full swing, and the blooms are splendid. With such weather as we have had for the last month, Roses will not cease to bloom until well on into the winter.

Fielding, New Zealand.

F. MASON.

[We thank our correspondents for the interesting letters, and shall be glad if other Colonial readers will send similar letters about plants in their countries.—Ed.]

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. A reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artists' or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLETS FOR EXAMINATION (*Enquirer*).—Your Violets appear to be attacked by eelworms at the root. We recommend you to have the frame scrubbed out thoroughly with carbolic soap, to remove all the soil, and replace with fresh which has not been used for growing garden plants in, at any rate recently, and to start with a new stock of plants from a fresh source. We would like to emphasise particularly the need for giving abundance of air on all possible occasions.

ANNUALS FOR DRY, SANDY, SUNNY BORDER (*Mrs. E. R.*).—Perhaps the best of all annuals for such a purpose is the dwarf Tom Thumb *Nasturtium*, a well-regulated mixture of which would provide a perfect floral mosaic. *Abronia umbellata* (Sand Verbena), Orange King Marigold (a superb bit of colour), *Chrysanthemum carinatum* in many beautiful shades, and *Godetias* in variety should do well. *Tagetes signata* pumila, T. Legion of Honour, *Nemophila insignis* and *Alyssum maritimum* are four excellent subjects for lines, ribbons or borderings. *Calandrinia grandiflora* should be quite at home in such a position, and so, too, should the Shirley and other Poppies. Ten-week Stocks, *Coreopsis tinctoria*, Sweet Sultans, *Dianthus Heddewigii*, *Erysimum perofskianum*, Candy-tuft and *Eschscholtzia* (the last two in many shades of colour) are others that should acquit themselves well in such a position. It is, however, high time the seeds of such things were sown. If you want good flowers and plenty of them, do not forget to sow thinly, subsequently thinning early to give each plant a chance.

THE GARDEN.

No. 2264.—VOL. LXXIX.

APRIL 10, 1915.

NOTES OF THE WEEK.

Our Sub-Editor at the Front.—We think the following note, written on March 28 by our Sub-Editor, Mr. H. Cowley, who is with the British Expeditionary Force "somewhere in France or Belgium," will be of interest: "The suggestion of quick-growing seeds for the soldiers is excellent. Rightful instances are now to be seen of dug-outs covered with verdant green turf, garden plots divided by red brick and clinker paths suggestive of an Italian garden design. Some plots are now bright with Cowslips, Lesser Celandine and fresh green leaves of the Cuckoo-pint—wild flowers previously lifted from meadows and ditches near the front. Yet the roar of heavy guns and the roll of the fire are incessant. Verily, the Briton is a born gardener. But why is it my London gardening friends will call the Cowslip a Primrose? Even the appreciative Peter Bell knew better:

A Primrose by the river's brim
A Primrose yellow was to him,
And it was nothing more."

The Gardeners' Royal Benevolent Institution.—We understand that Sir Frank Crisp has sent a cheque for £58 3s. out of the funds of the Institution, this being one quarter of the admission fees to Friar Park, Henley-on-Thames, last summer.

An Interesting Flowering Shrub.—*Corylopsis spicata* is one of the most interesting of the winter or early spring flowering shrubs, but it is by no means common. At the present time it is bearing its primrose yellow flowers in clusters of ten to twelve, the fragrance of which greatly resembles that of the Cowslip.

Corylopsis pauciflora differs from *C. spicata* in the flowers being paler and borne in pairs instead of clusters, while the leaves are also narrower. These shrubs are allied to the Witch Hazels and Parrotias, all of which bloom before the leaves appear.

A Handsome Buttercup.—In *Ranunculus repens* we have a handsome plant for the greenhouse, both for its large foliage and freely branched cymes of large, rich yellow flowers. Good well-grown plants form a bold mass, as they grow from 4 feet to 5 feet high and often 2 feet broad, and either mixed with other plants or alone they create a charming effect at the present time. By no means new, this beautiful species

from the Canary Islands is not well known, certainly not to the extent it deserves, as it is easily cultivated, and, although not quite hardy, only needs the protection of a frame during the winter.

Seasonable Work among Strawberries.—The hoe should be kept regularly at work between the rows of Strawberry plants until the flower-spikes become prominent, and at the same time a sprinkling of artificial manure may be applied carefully between the plants. If blanks have been caused during the winter, they should be made up with spare plants from the forcing stock.

Transplanting Evergreens.—The present time will be found the most suitable for transplanting

of snowy, green-tipped flowers in almost any position. The beautiful variety *carpaticum* has larger flowers and more yellow spots. By planting the Snowflakes in a bed of Mossy Saxifrage, the soft green carpet, studded with the drooping bells, produces a fine effect either in the rockery or flower garden.

A Dainty Spring Flower.—The little dwarf Hyacinth shown in the accompanying illustration is a well-known plant, yet we do not think it is grown anything like so extensively as its merits demand. Its botanical name is *Hyacinthus azureus*, but it is frequently erroneously described as *Muscari azureum*. Owing to its dwarf

habit—it rarely grows more than 5 inches high—it is a beautiful little plant for the rock garden, but to get the best effect the bulbs should be planted in small colonies, as shown in the illustration. When grouped in this way, in soil that is fairly porous, the pale blue flowers are seen to great advantage. It is a native of Asia Minor, and usually flowers in this country during March and early April.

Presentation to Mr. Frank Reader.—The many friends of Mr. Frank Reader will learn with pleasure that on the 17th ult. he completed his twenty-fifth year as chief cashier of the Royal Horticultural Society. In recognition of his valuable services during that period, the president and Council presented him on Tuesday, the 30th ult., with a handsome solid silver tea service, engraved as follows: "Presented to Mr. Frank Reader by the president and Council of the Royal

Horticultural Society in commemoration of the twenty-fifth anniversary of his appointment as Chief Cashier of the Society, March 17, 1915." This gift was supplemented by six solid silver tea spoons and sugar tongs from Mr. J. Gurney Fowler, treasurer of the society; six tea cups and saucers of Royal Worcester ware from the secretary, the Rev. W. Wilks; and a Japanese tea tray from other members of the staff. During Mr. Reader's term of office his courteous manner has endeared him to all with whom he has come into contact, and we sincerely hope that he may be spared many years to enjoy these practical recognitions of his services.

A COLONY OF HYACINTHUS AZUREUS, A CHARMING LITTLE BLUE FLOWER FOR ROCK GARDEN OR SHRUBBERY.

Hollies, Yew, Laurustinus, Box, and other evergreens, as the fresh roots are soon formed, quickly establishing the plants. Before filling in all the soil it is a good plan to give each plant a soaking of water. This also helps to work the soil well round the roots. Should the weather be at all dry, good waterings must be given until the plants have become established, and syringing the tops during bright, dry weather will be beneficial.

The Spring Snowflake.—This beautiful spring flower (*Leucojum vernum*) is now at its best, and to many would appear even more beautiful than the Snowdrops. It is just as easily grown, for rarely does it fail to produce an abundance

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Wattle Hurdles for Shelter.—In your issue for March 27 Mr. Molyneux of Swanmore writes as if he had discovered something new as a shelter for plants and shrubs, when, as a matter of fact, these hurdles have been made for several hundred years in the Southern Counties at a cost of about 7s. 6d. or 8s. per dozen, with stakes (or shores) for every two hurdles at 1d. each for folding sheep. Now, alas! in this age of cheapness, galvanised wire sheep netting is taking the place, on the cheaply run farms, of the wattle hurdles, as being easier to move, but to the detriment of the sheep and lambs, who lose the grateful shelter afforded by a fold constructed of wattled hurdles.

A Word to Daffodil Seedling Raisers.—Now that there are so many fine seedling trumpet Daffodils of all sections, it seems to me that it behoves seedling raisers to harden their hearts

early, and valuable time would be lost if one waited for the basal growths, which might not root owing to their sappiness. Generally speaking, the rooting of cuttings is not worth the trouble, save from a trader's point of view when he desires to increase a stock of a novelty. For garden purposes rooted cuttings are of little value. The plants obtained are never vigorous, and while they come into bloom more quickly than seedlings, the flowers are never equal to those of seedlings. Personally, I would advise amateurs to leave cuttings alone, for, apart from the inferiority of the plants, there is always a danger that the seedlings, deprived of their tops, will collapse.—T. A. W.

Grevilleas in Australia.—In your issue for December 19, 1914, you have, in the "Answers to Correspondents" columns, a reply to a correspondent who had sent a leaf for identification. You say "The name of the plant . . . is *Grevillea robusta* . . . it is a very good room plant . . . in its native country this *Grevillea* grows into a large bush . . . in the London parks it is employed

Though it varies in stature according to the conditions under which it grows in a state of Nature it would have been better had we referred to it as a tree. In this country, of course, it requires glass protection, and we have never known it flower here. We are much obliged for your interesting notes on *Grevilleas*, and also for your kind remarks on the enjoyment and information you derive from *THE GARDEN*.—ED.]

Undesirables in the Rock Garden.—I do not intend to write a further letter on the above subject, but I think "Alpinist's" letter in *THE GARDEN* for March 27 calls for a little comment. He says I sing the praises of *Cerastium tomentosum*. So I do, and I still hold that it is not a plant to be despised in the rock garden. Folks who live in the country (where so many things will grow) may prefer to devote its place to something more delicate and valuable; but townsmen especially (who, as I pointed out, often attempt a bit of rock garden, or, if not, a "rockery") cannot afford to do without this plant. I do not admit that it is undesirable in the rock garden, nor do I agree with "Alpinist" when he says that "the proper province of *Cerastium tomentosum* is that of an edging plant in borders." Your correspondent will find that it does not make a good edging, and, if he tries, he will find that the single *Arabis* makes a much better one. *Cerastium* is too free-growing for that; it is much the best planted where it can scramble down over stones in the rock garden. I have seen it growing in several rock gardens and in combined rock and walled gardens, as well as having it in my pieces of rock garden here, and the only complaint is that it grows so quickly; but this is hardly excuse enough for calling it undesirable. Your correspondent also says: "Fancy cutting alpine plants back twice a year as though they were some subject in a topiary garden!" May I ask him if he has grown the double *Arabis* for a few years together as an alpine in the rock garden? Surely he will remember what a rampagous grower it is, and that to keep it in bounds it has to be cut back once a year. Your correspondent writes without thinking. The cutting back of certain alpine plants is necessary work, though one would, of course, much prefer to let them grow naturally if only space would permit. "Alpinist" thinks that the *Arabis* is less of a nuisance than *C. tomentosum*. If I were asked which I thought was the undesirable plant of the two, I should say the double *Arabis*, inasmuch as it is far more rampagous than the other. [Query.—ED.] But I like both, and I think there are very few persons who would forbid the double *Arabis* in the rock garden, yet they denounce *C. tomentosum*, a much less rampagous grower. Many other plants—*Vincas*, some *Sedums* and certain *Aubrietias*, for example—have also to be cut back when they wish to exceed bounds, and if the work be carefully done, the plants look tidy very soon after. So I cannot agree with him. "Alpinist" goes on to quote from Mr. G. R. Phipps' letter, which was printed next to mine in the issue for March 13, *re* trees in or near the rock garden. May I point out that drip is not nearly so fatal to certain alpinists as "Alpinist" imagines. Certain of the strong-growing *Saxifrages*, many *Sedums*, some *Sempervivums* and other plants will do quite well even if there is a slight drip. Of course, I know that it is much the best to have a rock garden completely away from trees, but this cannot always be managed.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

A FLOWERING SPRAY OF THE MALE PLANT OF *RIBES LAURIFOLIUM*, A NEW EVERGREEN SPECIES FROM CHINA.

and discard any that—no matter how good in other respects—are short in the stem. A noted North Country grower wrote me not long ago: "I am in search of a good white trumpet Daffodil with a long stem, but I suppose that is what everybody else is on the look-out for." Our old friend Mme. de Graaff has had a good long reign, but it now transpires that it is not a popular flower in the market, and it does not need a very discerning eye to discover that shortness of stature is its fault. The ultimate and most desirable use and purpose of every good trumpet Daffodil is the market, and there length of stem is, and always will be, a pre-eminent qualification.—ORNATUS. [We do not think all our readers will agree with "Ornatus." Short-stemmed Daffodils, such as Mme. de Graaff or the Tenby Daffodil, are much better for wind-swept gardens than taller varieties.—ED.]

Sweet Peas from Cuttings.—Mr. William F. Rowles is in error on page 127, March 13 issue, in surmising that basal growths as they lengthen out would make better cuttings than tops. To do any good at all, the cuttings must be secured

as a dot plant," &c. There is some error. The *Grevillea* is represented by fifty-seven varieties, natives of all the Colonies, ranging in height from 2 feet to 100 feet and mostly flowering, the flowers ranging from white to red and yellows. The one you mention as *Grevillea robusta* is more popularly known here as the Silky Oak, and in Queensland, where it grows best (Queensland is largely tropical), as the Tuggan-Tuggan. It is an evergreen tree, 80 feet to 100 feet in height, and its flowers are orange in colour. This year here in Victoria it flowered beautifully, due to the dry winter and early heat. I may say I have subscribed to *THE GARDEN* for many years, and there is no paper I would not sooner do without than *THE GARDEN*. I get a great deal of information and enjoyment from it. It is the paper for keeping one up to date with all garden matters.—E. E. MORBEY, *Camberwell, Melbourne, Victoria, Australia*. [It is quite correct, as stated in our issue of December 19 last, that in a small state *Grevillea robusta* is largely grown for decorative purposes, being a good room plant, while in the London parks it is employed as a dot plant for summer bedding.

Vegetable Manure.—There are many good points in the note by "E. T. E.," page 153, issue March 27. I think if cultivators charred to ashes as much garden refuse as possible, including weeds, during the current year, and, in fact, every year, the results would be more satisfactory than simply consigning it to a hole as suggested. The object in view is laudable, but in some gardens the method would be a serious nuisance. From every side, would not salt be better to use at that stage than lime? There is a great clearance of Brussels Sprout, Cabbage, Broccoli and Kale stems in the spring. It is not difficult to burn them with other rubbish, and collect and store the dry ashes, which are clean and pleasant to apply at any time. Seeds of weeds, of course, perish in the fire and give no further trouble. I add fine cinders, a little coal slack and ordinary soil to the heap, and keep the fire going for many days.—AVON.

The Chatham Island Forget-me-not in Scotland.—The noble *Myosotidium nobile*, the Chatham Island Forget-me-not, is rarely seen doing well in Scotland or in the North of England. It suffers not only from cold in the winter, but also from gales injuring the handsome, glossy leaves, these often being made quite unsightly by the storms, especially in a place where an eddy is caused by the wind. In such a position the fine foliage is often hopelessly marred. It also requires a fairly warm place if it is to flower, and it is not everywhere in the North that all its desires can be met with such completeness as to induce it to live and bloom. The finest specimens the writer has ever seen in Scotland were in the garden of Mr. Kenneth M'Douall of Logan, Wigtownshire, a garden which many tender subjects evidently appreciate, and where many rare plants flourish amazingly. There, with a minimum of winter protection, *M. nobile* thrives in a manner which is the envy of those who are less fortunate. With its large, handsome, shining leaves and good blue flowers this Chatham Island Forget-me-not is quite a delight to see. I do not care so much for the white variety.—S. ARNOTT.

Antirrhinums and Disease.—In reply to Mr. E. K. Potter, page 135, issue March 20, I have had little personal experience of disease in Antirrhinums, but I think there is not the slightest doubt that his plants are infected with the fungus *Septoria Antirrhini*. If Mr. Potter can obtain Part II., Vol. XXXV. of the Journal of the Royal Horticultural Society (November, 1909), he will there find a two-page note, with illustrations, by Mr. Chittenden, F.L.S., on the subject. Spraying with Bordeaux mixture is recommended as a preventive. If I had infected plants, I should try this. I should apply it, I think, even if I had not infected plants, if I had been troubled with the disease in previous crops. Is Mr. Potter's soil well drained? This is essential to the good

health of the Snapdragon. Are his seed-boxes well drained? What is the source of his seed? Is it home-saved or bought? I am sorry I cannot tell Mr. Potter if his particular fungus is the same as the American one called by them rust disease. All I know is they have different names over there, e.g., *Puccinia Antirrhini* and *Colletotrichum Antirrhini*. As an old-fashioned cultivator, I believe the best way to ward off insect and fungoid attacks is to keep plants in good health and apply preventives in time. Some day I hope we shall go to the length of inoculating our plants to make them immune, just as our soldiers are immune to typhoid after the inoculation they undergo.

THE FEMALE FLOWERS OF RIBES LAURIFOLIUM.

Have not some of your numerous readers found a specific for the Antirrhinum disease? Although, as I said previously, I have had little experience of it, I was sorry to be told by Mr. Chittenden the other day that it is spreading in England. I often think we might be more communicative than we are. Some grower in some out-of-the-way corner of the land may have discovered something which would be beneficial to many. Let him take up his pen and tell us about it.—W. CUTHBERTSON, *Duddingston*.

FORTHCOMING EVENT.

April 16.—National Rose Society's Spring Show. Horticultural Hall, Vincent Square, Westminster

A NEW EVERGREEN FLOWERING CURRANT.

RIBES LAURIFOLIUM.

THIS is an interesting Flowering Currant of recent introduction from Western China. Two distinct characters are that the plants are dioecious and evergreen. Evergreen Ribes are not common. Others in cultivation are *R. gayanum* (*R. villosum*, *Botanical Magazine*, t. 7611), a Chilean species, and *R. viburnifolium* (*Botanical Magazine*, t. 8094), a native of Lower California and Santa Catalina Island.

R. laurifolium was introduced by Mr. E. H. Wilson in 1908 from Western Sze-chuan. He collected fruits in September of that year at an elevation of about seven thousand feet, describing it as an unarmed evergreen shrub up to 6 feet in height, not common. Cultivated plants in the Royal Horticultural Society's garden at Wisley, and in the garden of the Hon. Vicary Gibbs at Aldenham House, are 2 feet to 3 feet in height. On March 2 Messrs. J. Piper and Sons, Limited, Bayswater, exhibited male and female plants at the fortnightly meeting of the Royal Horticultural Society.

The coarsely toothed leaves are rich green in colour, with a rather leathery texture, up to 5 inches long and 2½ inches broad. The flowers are greenish yellow, borne on pendent racemes 1½ inches to 2½ inches long during February and March. The plants have stood unharmed outside through the comparatively mild winters of 1913-14 and 1914-15, but the recent frosts spoil the flowers on plants in the open. This suggests that the most satisfactory position for this Chinese Currant will be at the foot of a sheltered south or west wall. The plants thrive in good garden soil, and though coddling is not necessary, they require rather more attention than one is accustomed to give to the Flowering Currant, *R.*

sanguineum, in the shrubbery border. Propagation is done by layering, and by cuttings inserted in pots of sandy soil in gentle bottom-heat during July and August. With both male and female plants in cultivation it should also be possible to obtain seeds.

It is quite probable that this new-comer will prove a valuable shrub for the hybridist. The Ribes family is one that apparently might be considerably improved by crossing or hybridising, as several of the species, notably *R. sanguineum*, already referred to, are very popular shrubs especially among amateurs.

A. O.

NITROGEN, POTASH AND PHOSPHORUS.

THEIR EFFECT ON PLANTS.

ALL plants require at least ten of the chemical elements in order to develop properly. Most of these elements enter into the composition of the living material of the plant itself; the others are required to promote the chemical changes which are necessary to the growth and well-being of the plant. The complete absence of any one results in a cessation of normal growth; a shortage of any one results in failure to obtain the fullest development. One of them, the carbon, is obtained from the air; the other nine are got from the soil. The yield of a crop depends largely upon the presence of each of the nine in sufficient quantities in available—that is, soluble—form in the soil. Of these nine, only three are likely to be deficient in most soils—the nitrogen, the potash and the phosphorus. There are usually abundant stores of the remaining six.

Each of the elements plays a certain definite part in the nutrition of the plant, and on account of this an experienced person can generally tell whether any particular element is deficient by an inspection of the growing crop. He has to take many things into consideration in forming his judgment, and he can, perhaps, form it most easily when a mixed lot of plants are growing upon the soil, for each of the three I have referred to

phosphates as well, consisted wholly of grasses. Deficiency of nitrogen results in stunted growth of shoot and foliage, a poor, starved appearance, and yellowish tint generally. Conversely, excess of nitrogen results in vigorous development of large, soft leaves, sappy shoots and a deep green lush appearance.

Nitrogenous Manures, then, are to be used when it is desired to encourage large leaf development and succulent growth. Too much will cause the plant to become so sappy as to be an easy prey to insect and fungus pests. The form to be used must depend partly upon the speed with which the results desired are wished for. Nitrate of soda and nitrate of lime are most active, as they are most readily available; then follow sulphate of ammonia and calcium cyanamide, or nitrolim; then the organic manures. The last vary in availability, mainly according to the rate at which they decay.

Potash plays a different part. Without it the making of sugar or starch ceases; exactly why is not known. It may be actually necessary for the formation of these things, or its absence may interfere with their movement from place to place. Plants with a deficient supply, therefore, soon grow slowly, and they usually have a poor colour, while frequently the tips of the leaves die and turn brown. The epidermis does not appear to harden so much as when the supply of potash is sufficient, and Tomatoes and the like are more liable to crack as a consequence. Deficient

to reduce the amount of available potash by applying soluble potash salts, paradoxical as it may seem, and lime is the best key with which to unlock the potash again. On lighter lands kainit in winter, or sulphate of potash or wood-ashes in spring, are often an aid to better crops.

Phosphorus is best supplied as phosphates. Phosphates have an extraordinary effect upon root development, and are thus a capital preparation for periods of drought. They hasten ripening, and they further the storing of food in seeds. They are, therefore, particularly desirable wherever crops are wanted early, or where it is wished to encourage the ripening of wood, as with fruit trees and with tender shrubs in winter, and where crops are grown for their seeds.

Superphosphate is best where lime is present in the soil, and may be used in spring, as may bone-meal. Where the soil is heavy or lime deficient, basic slag should be used. SCIENTIST.

SOME GOOD GARDEN RHODODENDRONS.

DURING recent years a great deal of attention has been given to hardy Rhododendrons, stimulated, no doubt, by the numerous seedlings that have been raised in many gardens and nurseries from seeds sent home from China by Wilson and other collectors.

Already a number of these have flowered, and a few promise to make really good shrubs for garden purposes, while others would seem to be of botanical interest only. However, we need to know more about these before any definite statements can be made. Apart from these, however, we have a great many beautiful species and varieties that have been well tried in our gardens, and which, during May and June, impart to their surroundings rich Oriental effects such as cannot be obtained from any other shrubs. In the favourable climate of Devon and Cornwall a number of beautiful species, such as *Falconeri*, *argenteum* and *arboreum*, can be grown successfully in the open. At Tregothnan there is a wonderful specimen of *Falconeri*, which is a native of Sikkim. This plant has been known to carry as many as 1,200 of its large trusses of white flowers in one season. But these are not Rhododendrons for exposed gardens and less generous climates.

Fortunately, our hardy Rhododendrons do not impose any severe tax on the skill of the cultivator. It is true that in a few gardens the best skill does not prove effective, but this is the exception rather than the rule. What the majority do demand, however, is soil that is well drained,

practically free from lime, and preferably of a light, sandy and peaty character. This must not, however, be taken to mean that peat is essential for their well-being. The statement so often made that it is necessary has been exploded in many gardens, though no one would deny that the plants like it when it can be afforded them. But peat is not always easy to obtain, and, given a moderately light soil, this can be made quite suitable by adding to it liberal quantities of top spit from an old pasture, decayed leaves and thoroughly decayed manure, that from old Mushroom-beds being ideal. In a great many

RHODODENDRON COMPACTUM MULTIFLORUM, A DWARF VARIETY THAT FLOWERS FREELY.

encourages the development of a different set of plants. In the famous Rothamsted experiments, for instance, where potash and phosphates, but no nitrogen, were used in manuring pasture land, in course of time leguminous plants came to constitute half the herbage. Now, leguminous crops have, by reason of the bacteria in the nodules on their roots, means of getting nitrogen which other plants lack, so that it is evident that the leafy grasses were discouraged by the comparative deficiency of nitrogen, and the idea is strengthened by the fact that the vegetation on the plots receiving only nitrogen, or nitrogen, potash and

supplies of potash appear also to affect the colouring of fruits adversely. That their ripening is affected is evident from the fact that sugar formation is checked. Certain fungi are more easily able to attack plants suffering from potash starvation.

Potash Manures are wanted particularly by plants which produce and store large quantities of sugar or starch. Beet, Carrot, Potato, Tomato, fruit trees and the like are all benefited by the application of potash salts where they are deficient. Clayey, strong soils often need liming to unlock the stores of potash they contain. The peculiar composition of these soils renders it quite possible

gardens where the natural soil is a friable sandy loam, it is quite suitable for Rhododendrons without any more than ordinary preparation. The ground beneath the bushes should be carpeted with decayed leaves, so that the surface roots are protected from fierce sun.

Although spring—early April—is the season most favoured for planting Rhododendrons, specially the evergreen species and varieties, they can be successfully moved at the end of September and during October, or even later if the weather is open, though there is always an element of risk should severe frost set in directly after the work is done. Deep planting must be strictly avoided, an inch of soil over the uppermost roots being ample. If early autumn or spring planting is adopted, heavy waterings must be given to thoroughly soak the soil, and overhead syringing or sprayings daily for a fortnight should the weather be sunny and dry. Rhododendrons need little, if any, pruning; but it is very important to remove all seed-pods as soon as the flowers have faded. If this is neglected, the chances of getting a display of flowers the following year are small.

As already pointed out, there are now so many beautiful species and varieties that can be successfully grown in gardens situated in reasonably favourable localities that it is exceedingly difficult to make a selection of the best. It is doubtful if any two persons could draw up lists alike, as personal taste differs so widely. The following, however, are all good. Unless otherwise stated, they flower during May or June. All are evergreen. The height of garden varieties varies considerably, according to circumstances.

Alice.—A beautiful new variety, very compact, with rich, clear pink flowers. Too expensive for general planting yet, but is undoubtedly one of the Rhododendrons of the future.

Countess of Clancarty.—A charming Rhododendron that bears large trusses of light rosy crimson flowers.

Cinnabarinum.—A charming species from the Himalayas. It should not be planted in very cold, exposed positions, though it is quite hardy at Kew. It makes a rather upright bush, and produces its curious, pendulous, bell-shaped flowers fairly freely. These are of orange, red or crimson colour, and usually open in June.

Compactum multiflorum.—This is a dwarf variety, often below 2 feet high. It is of compact habit, with rather small leaves, and bears a profusion of white, pink-flushed flowers during April or early May.

Cornubia.—A new hybrid that is being very largely planted in gardens. The flowers are large and clear, and of a rich tint of glowing scarlet crimson. Very erect habit. It is more suitable for the warmer parts of the country than for general cultivation.

Fortunei.—This is a Chinese species of vigorous habit which bears large, delicate pink, fragrant blossoms which are distinguished from other kinds by their greater number of petals. A set of garden hybrids has been raised between it and other hardy kinds. They are free flowering and usually fragrant. Good ones are Miss E. A. Boulton, Mrs. Thiselton-Dyer and Duchess of York.

Caucasicum, an early flowering species from the Caucasus, is recognised by its compact habit

and early flowering qualities. The flowers, of different forms, may be white, or white heavily flushed with pink. It is one of the parents of the garden hybrids.

Doncaster.—A very compact-growing Rhododendron that produces its flowers in great abundance. These are glowing scarlet crimson in colour, and as they stand the sun well, it is admirably adapted for massing in beds where a gorgeous effect is desired.

Gomer Waterer.—This is a very beautiful variety, the flowers being freely produced on a bush of good habit. They are white, with a faint

would desire, but it is a very beautiful and charming variety.

Racemosum is a very beautiful species from Western China, which was introduced about a quarter of a century ago. Of dwarf habit, it takes many years to attain a height of 3 feet. It differs from most other kinds by its small rose-flushed flowers being produced in axillary as well as in terminal clusters. The flowering-time is April.

Campylocarpum.—This Himalayan species is worth attention in the milder parts of the country, for its large yellow flowers are distinct among those of the taller-growing kinds. Although

A BEAUTIFUL HYBRID FROM RHODODENDRON FORTUNEI.

tinge of pink, and the trusses are very large and pleasing.

John Waterer.—This is a very fine variety, the flowers being of good form and very freely produced in large clusters. They are intense glowing carmine in colour.

Lady Clementina Mitford.—Although some have a difficulty in cultivating this variety, it ought to be tried, if only for the colour of its blossoms, this being a charming shade of peach. The trusses are very large and shapely.

Mrs. E. C. Stirling.—This is a new variety of great promise. It has a good compact habit, and the flowers are freely produced in medium-sized trusses. They are unique in colour, inasmuch as the delicate pink flowers are quite free from spots.

Nobleanum.—This is, perhaps, the most interesting of all the outdoor Rhododendrons, as it is frequently in full flower at Christmas. It makes a tall, spreading bush, and the blossoms are of a pleasing shade of bright red. They are often damaged by frost. The best of all for forcing.

Pink Pearl.—It is quite safe to assert that there is more of this beautiful Rhododendron grown than of any other variety. It has very large flowers, borne in large trusses, of flesh pink colour, the delicacy of which it is impossible to describe. The habit is not quite all that one

usually considered a tender kind, it grows and flowers freely in sheltered positions in the neighbourhood of London. It is at its best in May. H.

SEASONABLE NOTES ON AURICULAS.

AT the beginning of April a few of the alpine varieties opened their flowers, and by the end of the month a grand display will be the general rule if the plants have received proper treatment during the rest of the year.

This is the time when the grower will realise whether he has been successful or otherwise. Strong, healthy spikes that need little or no support, with well-defined flowers, denote good cultivation; but where they are weak and of poor colour, something is wrong, and this must be rectified during the coming year.

General Treatment.—Now that the plants are producing their flower-spikes, it will be advisable to look over them daily to ascertain if any require water. On no account ought they to become dry at the base, or the blooms will be poor in quality and lacking in colour. Good colour is one

of the chief attributes of the Auricula. Plenty of ventilation is necessary, which not only improves the plants, but the cool air will prolong the life of the flowers. When the blooms begin to open, the early morning sun is beneficial; but later in the day a thin shading will be needed. Directly all the flowers are expanded, the sun's rays must not reach the plants, or the flowers will soon be ruined.

How the Flowers May be Shown to the Best Advantage.—Some growers like to exhibit their plants, while others keep them at home for the pleasure of themselves and their friends. The following remarks are applicable to both. There are exceptions to every rule, and a few spikes will, in all probability, require the aid of a thin green stake. This should be applied in the early stages of growth, or at any rate before the stem is bent over by the weight of the flowers.

Thinning Flowers.—Some of the trusses will contain more buds than can properly develop, and in such instances it will be necessary to thin them, but only two or three should be removed

Seed-Saving.—The only way to obtain new varieties is by seed. Careful seed-saving is most important, and no indiscriminate crosses ought to be made, while it should be borne in mind that a good pollen parent is as essential as a first-class seed-bearer. It is always advisable to keep the classes to themselves, such as mating a green edge with another of the same kind, and so on. With the alpinas a variety with a yellow centre should be pollinated with another plant having a centre similar in colour. Each flower must be carefully crossed, and the anthers ought to be removed from the selected seed-bearer before they expand. T. W. B.

DAFFODIL NOTES.

BY THE REV. JOSEPH JACOB.

Bibliographical Items.—A few notes on books wholly concerned with the Daffodil may be of interest. I recently submitted a list of them to

grounds for his statement, for the late F. W. Burbidge was unable to come across it, and borrowed old Peter Barr's in order that his wife might copy it out in manuscript. I am the proud possessor of this, which has a note in Burbidge's own handwriting stating the above fact. What, however, gives me even more satisfaction is the possession of an original, which I accidentally came across in a second-hand bookshop "somewhere in England," and which, on my producing and leaving certain round, flat objects, I was allowed to carry away. Haworth's monograph is the first attempt to classify in a botanical way the Daffodil family, and as such must always have a special interest, although more recent workers have proved many of his deductions to be wrong. His main fault was classifying as species forms which were only varieties. Another item which has a little history attached to it is "Ye Narcissus or Daffodyl Flower," by F. W. Burbidge. This was published by Barr and Sons in 1884. Anyone who has

examined it cannot fail to have been struck with the curious, large black ornamentations on the tops of many of its pages, and also with a somewhat aggressive one on the cover and on the inside title-page. Thereby hangs a tale. Hartland of Cork had already brought out a list which he called "A Little Book of Daffodils," when Barr and Sons published their work, "Ye Little Booke of ye Narcissus," &c. The fat was in the fire, as those of us who knew old Baylor Hartland can well imagine. And the end of it was that the offending words, "Ye Little Booke," had to be obliterated. I possess a copy of the original issue with no obliterations whatever; also one with the obliterations done in quite a different style from what they were later; and, lastly, what I may call an ordinary copy. The book is scarce, but it is sometimes to be met with in second-hand book catalogues. I need hardly say that it is a veritable mine of information on all that pertains to the Daffodil. It is not everyone who knows about the "little breeze" that its first appearance caused.

N. eyclamineus.—Many people, like myself, have doubtless found this variety difficult to manage. Wise people, however, live and learn. I

hope that I have now found out how to manage it, from what I saw in the Rev. W. Wilks' charming coppice garden at Shirley, where, on a light soil, carpeted with Ivy, numerous colonies were flowering in rude, vigorous health. No bulb had ever been planted. Seed had been sown when he went there six or seven years ago. Now the plants seed themselves, and are spreading in many directions. Evidently cyclamineus requires light soil, the nurturing influence of friendly roots, and slight shade overhead in summer.

Flowers at the Royal Horticultural Society's Hall on March 30.—Daffodils are sadly hanging fire this year. Whereas on the corresponding date of last year the season was at its height, I can only report of the current one that it has hardly begun. The only open-air grown flowers came from Devonshire or Cornwall. The sole group was that put

HARDY RHODODENDRONS GROUPED FOR EFFECT.

at one time. A pair of small scissors or tweezers may be used for this purpose. The alpine varieties do not require a lot of thinning, but show kinds are subjected to more severe treatment, particularly the greens, greys and whites. If a fancier can secure four or five good flowers upon each stem, he is generally satisfied; but those who do not exhibit may leave one or two more, though overcrowding must be avoided. The selfs are also thinned, but not quite so severely. A fine truss of bloom should be the object, and with this in view few will go wrong in removing superfluous buds. A few points to be observed by the exhibitor are careful handling of the plants to prevent injury to the flowers and the farina or meal upon the leaves and stems; see that the pots are clean and have a neatly written label, and put a layer of fresh moss around the base of each plant.

my friend Mr. Harman Payne, whose knowledge of purely *florist* garden books is all-embracing, which was returned with the remark "perfect." Far and away the rarest is the "Narcissinearum Monographia," by A. H. Haworth, which was published in London in 1831. It is called the second edition on the title-page, but, all the same, it is the first and only one which has a separate existence as a book or pamphlet by itself. The first edition was issued as a supplement to the first volume of the second series of Robert Sweet's "British Flower Garden," and this second edition was brought out to correct certain errors in the first. As Quaritch might say in one of his lists, it is excessively rare, so rare, in fact, that I wonder if he has ever had one for sale. The late Peter Barr possessed a copy, and he said he believed it was the only one in existence. He had good

up by Messrs. Barr and Sons. It contained many beautiful seedlings—for the most part trumpet forms. I thought the *tout ensemble* of the whole excellent; so did the Narcissus committee, who awarded it a silver-gilt Flora medal. Two charming cyclamineus hybrids were shown for the first time, and as they are increasing every year, there is a likelihood of their growing into stocks. Golden Arrow is very similar to the hybrid pictured in THE GARDEN for March 27. The dimensions are very nearly the same, so is the colouring. The other one is a much deeper shade of colouring, and has wider segments and a shorter but more flanged corona or trumpet. There are now six plants of this, so I hope it will remain with us.

A most interesting little Tazetta appeared in public for the first time, under the name of *T. canaliculatus*. This is a wild form from the Riviera. The stems are 7 inches or 8 inches high, the perianth is much reflexed, and the colouring is that of *Gloriosa*. From Moggridge's account of it in his "Contribution to the Flora of Mentone," one would have expected a starry perianth, for no mention is made of any reflexing.

Messrs. Carter's pretty display of Daffodils and Crocuses, and further comments on that of Messrs. Barr and Sons, I leave till next week.

A BEAUTIFUL HARDY PLANT.

MECONOPSIS WALLICHII.

IT is a tribute to this, the noblest and best of its tribe, hailing from the mountains of Sikkim at elevations varying from 12,000 feet to 14,000 feet, that, as a garden plant, it is also one of the most tractable. Often seen in the highest perfection—though never, perhaps, in sufficient numbers—rearing its glorious pyramids of mauve-coloured, saucer-formed flowers to a height of 7 feet or thereabouts, it is at such times a plant of commanding presence and high distinction, one which no flower-lover could ignore, while many would be fascinated by its charms.

While the accompanying illustration will afford some idea of the form and outline of this fine species at flowering-time, neither this nor a pen-picture could possibly portray a tithe of the beauty of which it is possessed. It is at such a time that the scores or hundreds of its 3-inch wide, mauve-coloured flowers appeal, their plenitude as forcibly, perhaps, as their indescribably beautiful colour. In these respects it is a plant to be seen, and remembering its beauty may remain for weeks, there is abundant opportunity for intimate acquaintance.

In winter-time its well-developed rosettes of leaves would attract any plant-lover. In their highest excellence these may reach to 2 feet or more across, their grey-green ground colour shrouded by innumerable soft reddish brown hairs, ever a conspicuous feature in rock garden scenery.

Biennial in character, or to be so regarded from the cultivator's standpoint, it is a subject

to be dealt with on definite lines if success is courted. A tantalising fact in respect to this species is the apparently large number of good seeds a plant yields and the comparatively small proportion of which vegetate. Other members of the genus have their idiosyncrasies, and, so far as I know, the above is the general experience of this particular kind. In any case, seeds are best sown a few weeks after maturing, September and October being perhaps the most suitable time, and preferably in a greenhouse temperature of 45°, which assists—one might say ensures—a more prompt vegetation. Sown under cold frame conditions, the results are less satisfactory and vegetation slow. So treated the earliest seedlings appear in about a month, and, pricked off with care when large enough, should be grown

about equal parts. Coolness and summer moisture are important. Those desiring a good seed crop should hand fertilise the earliest flowers with a view to obtaining the same. E. H. JENKINS.

THE MOST USEFUL DECORATIVE PALMS.

THE last twenty-five years have seen a great increase in the number of Palms grown for decorative purposes. In some of the large trade establishments the more popular kinds, such as the Kentias, are grown by hundreds of thousands, and so cheaply are they sometimes disposed of that well-furnished specimens may be frequently seen hawked around the streets of London and suburbs.

The various Palms are all increased by seeds, which are sent to this country from various quarters of the globe. As the germinating power of some of them at least quickly weakens, the seeds should be sown as soon as possible on receipt. For Palms in general a loamy soil is more or less necessary, a suitable compost for the free-growing kinds being from two-thirds to three-quarters of good turfy loam, according to its constituency, and the remainder made up of leaf-mould, well-decayed manure and sand.

The present is a very suitable season to repot the different Palms that require it, as the young roots will soon take possession of the fresh soil. With regard to repotting, it is as well to bear in mind that good specimens may be grown in comparatively small pots, provided they are well supplied with water and given an occasional stimulant during the growing season. This is often a very important consideration, for when Palms are used for decorative purposes indoors, they are frequently dropped into vases or jardinières, many of which do not permit of a very large pot being used.

In most Palms the roots are of a deep descending nature, and find their way at once to the bottom of the pot, around which they coil, and in time will lift the ball of earth entirely. When repotting such as these, it will be found that an ordinary flower-pot is not sufficiently deep unless a very large pot is used, and then the plant will be what is termed "overhatted," that is to say, the width of the pot will be out of all proportion to the plant growing

therein. Furthermore, Palms do not like a mass of soil around their roots, which is the case when inordinately large pots are used. To overcome this difficulty, I have had pots made a good deal deeper in proportion to their width than those usually met with, and found them a great advantage in every way.

Palms of all kinds thrive best in a fairly shaded structure with a considerable amount of atmospheric moisture, so that they may be freely syringed, particularly during hot weather. They must also be liberally watered at the roots, but

MECONOPSIS WALLICHII, A BEAUTIFUL HARDY PLANT FROM SIKKIM WITH LILAC BLUE FLOWERS.

on steadily throughout the winter under similar conditions, potting them on as they appear to need it.

These earliest seedlings by the ensuing May should be strong examples in 5-inch pots ready for their permanent positions. Developing during the year of planting to the extent already indicated, the plant commences its flowering in July of the following year, remaining attractive for weeks. At no time during the early stages should the seedlings be coddled or forced. A sturdy growth is essential to success. The plant revels in rich vegetable soils—peat, leaf-mould and loam in

at the same time stagnant moisture is very injurious to them. In the case of all Palms, a sharp look-out must be kept for scale insects, to which they are somewhat liable. Should any of these pests put in an appearance, they may be got rid of by sponging with warm water in which some soft soap has been dissolved, while, if necessary, the scale should be loosened with a pointed stick, taking care at the same time not to injure the leaves. It will be found that in the case of these pests "a stitch in time saves nine," as if they are allowed to increase, which they do rapidly, it is not so easy to get rid of them.

Palms in the Dwelling-House.—

Complaints are often made that Palms purchased in a perfect state soon become unhealthy when taken indoors. This may be caused by various circumstances, but probably the most general is that in order to obtain good saleable plants in as short a time as possible, they are subjected to a considerable amount of heat and moisture to push them along. Naturally, when taken into the dwelling-house, and particularly if the weather is cold and fires extensively used, they feel the change very much, and the leaves become more or less yellow. To prevent this as far as possible, a good plan is to purchase the plants about the end of May, when the difference in temperature will not be so great as when the weather was colder, while there is ample time before the winter comes round for them to become used to their surroundings. Except during very cold weather, Palms in the dwelling-house should be sponged about once every ten days with lukewarm water. It is very essential that the under as well as the upper sides of the leaves are so sponged, as this tends to keep away insects. In the summer especially they need to be well watered, but on no account must the water be allowed to stand in the saucers or jardinières in which they are placed. A good plan, when the plants are but few and can be conveniently handled, is to take them to the sink or some other convenient place, soak them in a pail of water, and allow them to drain before returning them to their quarters. In the summer the plants should be so situated that the sun does not shine full on them after eight o'clock in the morning. During a warm, soft rain they are benefited by being stood out of doors. When the pots are well furnished with roots, an occasional stimulant will be helpful. Some of the chemical plant foods that have little, if any, unpleasant smell are the best. In winter, when the nights are cold, do not leave the plants in the window, as they are much safer in the centre of the room.

Among the most suitable Palms for decorative purposes, the first place must be assigned to the Kentias, which are so universally grown. Of the two species, the taller and bolder is *K. forsteriana*, while *K. belmoreana* is of dwarfer

growth, with more finely divided leaves. Others that can be recommended are *Chamærops humilis*, a pretty little Fan Palm from Southern Europe; *Cocos weddelliana*, with much divided leaves, which needs more heat than most of the others; *C. flexuosa*, a tall grower with pinnate leaves, much used for the background of groups and similar purposes; *Corypha australis*, a Fan Palm with spiny leaf-stalks, bearing exposure to draughts better than most Palms; *Geonoma gracilis*, somewhat like *Cocos weddelliana*, but more graceful, yet needing the same treatment; *Latania*

FORSYTHIA INTERMEDIA SPECTABILIS, A VERY FREE AND EARLY FLOWERING HARDY SHRUB.

borbonica, a large-leaved Fan Palm more grown at one time than it is now; *Phoenix* (Date), the most ornamental of which are the large-growing *P. canariensis*, the medium *P. rupicola*, and the small but exceedingly graceful *P. Roebelini*; and *Seaforthia elegans*, which before the Kentias were so general was much grown, but it is not now generally met with. It attains quite tree-like dimensions.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Odontoglossum Mars.—A hybrid remarkable for colour, fine form, density of flowering, with blossoms of great substance. Having a certain leaning to *O. illustrissimum*, the shapely flowers, with well-imbricated sepals and petals, are of brownish crimson hue, finely bordered with purest white. The lip is also white. A conspicuous feature is the pronounced bloom overlying the dominant colour, this imparting a richness that is quite unique. Of sturdy habit, the branching spike is erect, the flowers of large size, arranged with unusual density. It is a very handsome variety.

Lælio-Cattleya J. F. Birkbeck (*C. Mendelii* × *L.-C. Henry Greenwood*).—A variety unusually large in all its parts. The sepals and petals are of blush pink tone, the handsome fringed lip of rich purplish crimson, and the throat yellow lined. These two superb novelties were exhibited by J. Gurney Fowler, Esq., Brackenhurst, Pembury, Kent (gardener, Mr. J. Davis).

AWARDS OF MERIT.

Forsythia intermedia spectabilis.—

Of a few shades deeper yellow than the well-known *F. suspensa*, this fine flowering shrub is also characterised by greater density of blossoming, the exhibited example, 5 feet high, being laden with its golden yellow flowers. Quite a valuable plant among the earliest flowering hardy shrubs of the year. From Mr. M. Prichard, Christchurch.

Carnation Mrs. G. Lloyd Wigg.—

A pure white sport from *R. F. Felton*, and those who know this fine variety will not require any further recommendation. Strangely, too, for a sport, it is endowed with a pronounced Clove perfume, which the original does not possess in like degree. The flowers are handsome in size and pure in colour. From Messrs. W. Wells, Limited, Merstham.

All the foregoing plants were shown before the Royal Horticultural Society on the 30th ult., when the awards were made.

THE MOUNTAIN TULIP.

(*TULIPA MONTANA*.)

The rock garden is made much more attractive by planting among the other plants some of the dwarfer bulbous flowers which supply features distinct from those usually possessed by the flowers which are the general objects of the taste of the alpinist. These should be dwarf in stature, bright or pleasing in other points besides colour, and should also be fitted to become permanent occupants of the rock garden with as little need of lifting and replanting as possible.

The dwarf Tulips afford us some flowers of this category, and among them a suitable and charming subject is offered by *Tulipa montana*, a very dwarf species only a few inches high. It has nice scarlet flowers, adorned with a black and yellow blotch at the base of the bloom. It is thoroughly hardy, but likes a rather sandy soil and a sunny position in a sheltered nook which is well drained. It flowers during March and April.

H. P.

S. A.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE most forward plants will now require considerable space, and as frame accommodation will be limited very considerably at this time, only those plants that are really required should be retained in them. The wise amateur cultivator should make a list of all the plants he will need for various purposes, namely, for exhibition, for greenhouse or conservatory decoration, for late flowering, for the supply of cut flowers, and for the open border. It is astonishing how the total swells when even a few pots of each section are grown. The summer accommodation may be ample, but the space under glass in the autumn very limited. All these points must be considered. It is much more satisfactory to grow just the number that can be easily dealt with and given proper treatment throughout than to have too many.

A Brief Guide.—To obtain twelve cut blooms for exhibition, grow twenty-four plants in not fewer than eighteen varieties; if some are duplicated, in fifteen varieties. To have six blooms on long stems for vases, one variety, six plants should be grown. To be able to stage eighteen blooms, six varieties, three blooms of each, grow at least thirty-six plants in not fewer than nine varieties. For cut blooms for home vases and for plants for decoration, specimens bearing from six to fifteen flower should be the rule; then the required number of plants can be easily estimated. The single-flowered sorts should be grown on the same principle as the decorative varieties, as the highest class blooms are usually from late-formed and terminal buds.

Repotting Late-Struck Plants.—At this season, when the newly rooted cuttings are in very small pots, close attention must be given to the matter of watering and repotting. I have seen the small plants, whose roots have been constantly dried up—almost parched—become quite hard of stem and small of leaf before the end of April. Such plants rarely, if ever, make stocky, robust specimens. When in a fit state to be repotted, give them the necessary shift without a day's delay.

General Repotting.—This work has a direct effect on the first break caused by the formation of a bud in the point of the plant. If the plants remain potbound for a few days or a week, the formation of the bud is hastened. Then on the resultant side shoots the important and keenly looked-for crown buds show too soon, and if retained "taken," develop into badly coloured, coarse blooms. If removed, the later buds that form are inferior as regards size, and develop probably too late for a special purpose. Only in the case of naturally late-flowering varieties does the potbound condition of the plants have any beneficial effect in this matter. By probably causing the first break a week earlier in the spring, the coveted first crown bud is secured early in August; then, other matters being favourable, all is well.

Green and Black Aphides.—Cultivators must be on their guard against these pests, as they increase so very rapidly and do much damage to the young shoots. If allowed to infest the young shoots for even a few days, they cripple the growth, and in later stages the expert can point out where the check occurred. Very fine Tobacco powder sprinkled on the affected parts and syringed off two days later usually frees the plants of green

aphides. For black aphides the ends of the shoots should be held over a saucer while the powder is put on, as if the plant retains its upright position, the pests drop wholesale to the lower leaves and then regain their place at the top. There are valuable insecticides to be obtained from firms advertising in *THE GARDEN*, which are very efficacious if used according to the instructions given with them.

Stopping Plants.—Many of the naturally late-flowering varieties should be stopped during the latter part of April; that is, the point must be pinched off if a bud does not form, to cause a natural break.

AVON.

ROSE-GROWING IN TOWN GARDENS.

BY the time these lines appear in print the much-debated question as to which is the most favourable time for cutting back one's Roses will in many cases have been satisfactorily settled. The operation should depend upon the calendar, and is best fixed definitely at a time which experience has shown to be suited to a particular district. Those who would postpone the operation because the weather happens to be cold at the time can hardly appreciate the effect of it. It is the temperature some three or four weeks after pruning that concerns us most, for then the eyes to which the growths have been cut back will have developed sufficiently to be affected. As we cannot foresee these cold spells in store, it is best to keep strictly to the week appointed.

From now onwards is the time for those rosarians who are also diarists to get busy. Gardeners who have not cultivated this habit should learn to do so, and they will find that the few minutes taken up each day in noting progress will be amply rewarded. With Roses it is especially interesting to compare the time of appearance of one's favourites from year to year, the length of their flowering periods, and other matters of import. To the exhibitor the practice is valuable, for there are no other means by which the duration of flowers can better be gauged than by studying the progress made in previous years, and he can also learn to estimate as nearly as it is possible to do the time which the buds will occupy in development.

The winter rains will have beaten down the soil upon the surface of Rose-beds until it has become caked hard. No time should be lost in loosening it, and those who intend to add a mulch of manure to their beds should defer doing so until the hoe has been used. This early aeration of the soil has a most beneficial effect upon the roots, which are now coming to their most active period, and require all the stimulating that one can give them.

From the Rose-grower's point of view the past winter (in the Southern Counties, at all events) has been anything but unfavourable, and there are very few losses. The frosts have been of such short duration that they have proved almost harmless, and many of the Teas have not yet shed last year's foliage completely. Cases of flowers opening out of doors have been almost continuous. Perhaps one of the most exceptional was that of Mme. Edouard Herriot, of which I saw a fully expanded bloom in early February. It was poor in colour, but quite recognisable, and this certainly goes to prove the reliability in opening of this beautiful variety. P. L. GODDARD.

NOTES ON CARNATIONS.

Carnations in Mixed Borders.—The Carnation is one of the plants suitable to furnish those parts of the mixed flower border occupied by early flowering bulbs, and, as soon as these are over, the former may be planted. The ground need not be loosened, and manure is best supplied by surface-dressings from time to time. In case anyone should feel qualms about planting in firm soil, there is no reason for such, firmness being almost a necessity in the rooting medium of the Carnation; and as showing that the writer has no fear in that respect, it may be noted that a lot of the florist's type of Picotees and Carnations have recently been planted on ground undug since the previous crop. The plants should not be very close—15 inches apart, perhaps—and any time in April or early in May a few seeds of Virginian Stock sown in the intervening spaces will, a few weeks afterwards, render the groups gay.

Growing Border Carnations in Pots.—It may be news to some that the Carnation has been cultivated in pots for centuries, and for long none but singles and those which the florist of the day would designate "rubbish" were planted in the open. Those who have seen the extensive cultivations of the late Mr. Martin Smith and Mr. Douglas need not be told of the striking beauty of housefuls of Carnations of all types, and these two cultivators did much to popularise this very old way of treatment, which had fallen about the middle of last century into desuetude. Neither employed such large pots as earlier cultivators, and very nice material can be produced in 7-inch pots, while 9-inch pots are quite large enough to embrace triples.

The Best Soil.—The old growers, again, were very particular regarding composts, in England perhaps following instructions contained in two French monographs of the seventeenth century. In a translation of Van Oosten's "Dutch Gardener," "Horse-dung that is quite rotten" is recommended as the one material necessary. So impressed do our own cultivators seem to have been with the value of this material that Maddocks at the end of the eighteenth century, made his compost of one-half of rotten horse-manure, one-third of sound loamy earth, and one-sixth of coarse sand. Hogg, thirty years later, used five parts of loam, ten parts of horse-manure from frames, and one part (the minimum) of coarse sand. Anyone who can grow the common Zonal Pelargonium will find this section of Carnation to succeed very well in a similar compost. It must be understood that the manure used by the old practitioners was thoroughly rotted. Some recommend that it should not be used till reduced to the state of "mould" or earth, and also it must be remembered that the value of rotted turf was not then known, the large quantity of manure no doubt being employed to keep the soil open, and, indeed, the whole method of potting was different.

Manure in the Soil.—For my part I do not care about using any manure in the compost. It is an easy matter to apply it on the surface or in water as the plant requires it. It is a curious fact that such a hardy plant as the Carnation undoubtedly succeeds better in the North under the shelter of a glass roof than it does when stood in the open without any protection during the summer months. The value of roof protection is enhanced by the plants flowering earlier than those in the open.

Prestonkirk.

R. P. BROTHERSTON.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Midseason Vines.—The shoots on Vines in active growth will need constant attention in regard to stopping and training. If the Vines are growing quite near to the glass, much care and patience is needed in securing them to the trellis. The work ought to be done, if possible, either during dull weather or late in the afternoon, as there is considerable danger of the shoots breaking when the sun is shining full on the house. When the bunches have set, there should be no delay in removing the surplus bunches. At this stage the borders must be examined to see if they require water, and if it is needed, they must be slightly forked up and thoroughly soaked with diluted liquid manure. At this time of the year the berries should be thinned with as little delay as possible, as they swell very quickly.

Late Muscat Vines.—Before the Vines come into flower, the borders must be watered, if necessary. All shoots which require stopping should be attended to before flowering commences, so that there shall be no check to growth while the bunches are setting. If the shoots are not touching the glass, tying ought to be deferred till the bunches have set, as the berries set better when well exposed to the light. During the flowering stage a mean temperature of 70° must be maintained, and the ventilators carefully manipulated at all times to prevent any sudden fluctuations of the temperature.

Plants Under Glass.

Euphorbia jacquiniæflora and E. pulcherrima.—As soon as cuttings are available, they must be inserted. They require a brisk bottom-heat, or many of the cuttings will fail to root. Insert the cuttings singly in 2½-inch pots, either in fine sand or a light sandy compost. Further batches of cuttings should be inserted as they become ready.

Panicum, Isolepis gracilis and Pilea muscosa.—These are excellent plants for the edges of groups, and should be propagated annually. *Panicums* and *Pileas* may be propagated easily from cuttings inserted in 3-inch pots. *Isolepis gracilis* can be increased by division of the old plants. These divisions make excellent plants if potted into 3-inch pots and placed in a warm, moist house for a few weeks.

Crotons and Dracænas.—Recently rooted plants must be grown on in plenty of heat and moisture. Crotons need a position in the lightest part of the stove, in order to produce good colour in the foliage.

The Flower Garden.

Violets.—Young plants that were rooted in frames last autumn may now be planted out. A border which is somewhat sheltered from the sun should be chosen for the summer quarters of the Violet, as in such a position the plants are not so likely to be attacked by red spider. The ground which was dug and well manured some weeks ago must now be forked over, and the surface made level with the rake. The single varieties may be planted about a foot apart, and the doubles a little closer. If young plants are not available, the old ones may be divided, selecting the most promising crowns for planting. When planted, keep them regularly supplied with water, and during warm, sunny weather spray them every afternoon with a fine-rosed can. A dusting of soot occasionally will help to keep red spider in check, and will also act as a valuable stimulant.

Sweet Peas.—Seedlings in pots or boxes may now be planted out. Put them in shallow trenches, and, should the soil be on the wet side, a little dry soil from the potting-shed will facilitate the work. When planted, the young growths must be supported with small twigs, and, to keep birds off, strands of black cotton should be placed over the rows.

Pansies.—Seeds can now be sown for raising plants for blooming in the autumn. Varieties that are worth perpetuating may be propagated by dividing the old plants, inserting the best portions in a shady position outdoors.

The Hardy Fruit Garden.

Aphides.—A sharp look-out must be kept for green and black fly, which play havoc among crops of stone fruit if they get well established on the trees. Their presence may be detected by the curling of the leaves. To keep the trees clean, there is nothing better than a systematic method of spraying. A mixture of soft soap and sulphur will be found safe and effective in dealing with these pests.

Red Spider and Thrips.—These are more difficult to deal with than aphides when once they obtain a footing on the trees, and a stronger insecticide must be used to destroy them. The Cherry is often attacked by small caterpillars, which roll themselves up in the leaves. These should be sought for and picked off with the fingers, for if allowed to remain they will attack the fruits as soon as they have set.

The Kitchen Garden.

Spinach.—To ensure a good supply of this valuable vegetable, liberal sowings must be made. The old plantations may yet be induced to supply plenty of good leaves by using the hoe freely between the rows.

Peas.—Further sowings must be made to ensure plenty of pods during the month of July. The ground for the later sowings should also be prepared, if not already done. Attend to the staking of the early plants before there is danger of injury by rough winds, and during showery weather dust the rows with well-seasoned soot to promote a healthy growth.

Onions.—The seedlings that were raised in boxes ought now to be ready for planting out, providing they have been well hardened off. Endeavour to transplant them with as little disturbance to the roots as possible. Sprinkle with water in the afternoon, should the weather be dry, till they have become established.

Leeks.—The earliest batch may now be planted in ground which has been thoroughly prepared. If high-class Leeks are to be grown, they should be grown in trenches and treated much the same as Celery.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Fruit Under Glass.

Strawberries.—As the fruit shows signs of ripening, feeding with liquid manure and fertilisers should cease. Although the plants would quickly suffer from lack of moisture, overwatering at this stage must be avoided if the fruit is to be of good flavour. Plenty of fresh air is another very important factor, as well as sunshine, in the production of well-coloured and highly flavoured fruit.

Heating.—Excessive heating of the pipes in fruit-houses is very injurious, and tends to encourage insect pests. Except on cold or damp days, the fires should be checked early in the morning, and not disturbed until well into the afternoon. At the same time, it is never advisable to allow the fires to go completely out, as a sudden change in the weather may require heat to be quickly generated.

The Hardy Fruit Garden.

Fruit Plantations.—The hoe must be used freely, even if weeds do not exist, as this is a good mode of preventing too rapid evaporation of moisture from the soil. Where the soil has become caked, hoeing also allows a free passage for the air.

Strawberries.—As the plants are now growing freely and will soon be forming their flower-trusses, a little extra help might be given in the form of some artificial manure. After giving some to each plant, the surface should be lightly broken up either with the hoe or fork.

Grafting.—This operation ought now to be attended to where it is purposed to use the stock of some undesirable kind of fruit tree to better advantage by grafting it with an improved variety. There are various methods, but the most important point to remember is that the stock to be used must be showing evident signs of growth, while the scions should be almost dormant.

Plants Under Glass.

Primulas.—If a succession is desired of either the *sinensis* or *stellata* varieties during the winter and spring, a start must now be made by the sowing of seed. Plenty of good leaf-soil and silver sand should predominate in the compost required for these plants while they are small. A warm greenhouse will be a suitable place in which to germinate the seed.

Decorative Chrysanthemums.—The majority of the plants will be ready for potting on into 6-inch pots, and as far as possible should be completed during the next ten days or fortnight. The potting compost ought to be fairly rich, as it will have to sustain the plants until the end of May or early in June. These after being potted should be stood on ashes in cold frames. A dusting of soot on the ashes will keep worms and vermin in check.

Plumbago rosea.—Plants which have been resting ought now to be returned to a stove temperature, when they will quickly become active again. As the young growths appear they should be made into cuttings until sufficient stock has been obtained. This plant will grow quite well if shaken out and potted on for a second season; but as cuttings are so easily rooted, it is best to raise a batch of young plants each year.

The Flower Garden.

Roses.—After the pruning is completed, the beds and borders should receive a dressing of manure. Well-rotted cow-manure with as little litter as possible is best; but, failing this, some reliable Rose fertiliser may be used. Care must be taken that neither buds nor roots are injured during the forking in of the manure.

Nemesias, to commence flowering in July, ought now to be sown. The *Nemesia* is an annual difficult to surpass for brilliancy of colour, also an almost perpetual flowerer from the time it commences right on until the frosts of October or November finish its career.

Sweet Peas.—The ground having now settled and become firm, a start may be made to put out the young plants. If extra fine flowers are desired, they should not be planted at a less distance apart than a foot to 15 inches. Slugs and snails are very fond of Sweet Peas, and when planted they ought to be surrounded with soot and lime. If the weather should prove very wet, the soot is apt to lose its effect by being washed into the soil, and must be replaced by a liberal application of sharp, gritty sand or wood-ashes.

Sunflowers must be sown so as to get nice-sized plants for setting out by the end of May. After germination has taken place, they should be kept as cool as possible, and try to keep the plants dwarf by placing them near the glass.

The Kitchen Garden.

Spring Cabbages.—As these are now quickly developing, a little more help may be given by applying a small quantity of nitrate of soda round each plant. When this has been done, the ground should be gone over with the Dutch hoe. This will benefit the plants, besides keeping down weeds.

Celery.—As the young plants become large enough to handle, they must be pricked off closely together in boxes. Here they may remain until a frame can be spared for them, which will give them more room to develop into good plants for planting out later on.

Spinach.—More seed must be sown to keep up a succession of this vegetable until the season has become too hot for its successful cultivation. The crops already growing should receive a good hoeing.

Lettuces.—Where one has a sheltered border at the foot of a south wall or glass house, a portion of it should be used for growing early Lettuces to succeed those grown in frames and on hot-beds. Plants from seed sown our or five weeks ago are now ready to put out on this site. As slugs are bound to attack them, soot must be catered around as a means of prevention.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ANNUALS IN BORDER (W. D.).—The simpler and more effective way of arranging the plants would be to form crescent-shaped bays along the whole of the front, outlining them with the dwarfest things, as *Alyssum* or *Tagetes signata pumila*, and planting the front bays with *Nemophila*, *Eschscholtzia*, *Candytuft* (white), *Phacelia*, *Candytuft* (carmine) and *Nemesia* in the order named. To do this throughout the border it might be necessary to repeat the arrangement, employing a distinctly taller subject, such as *Godetia*, for the centre. For the back the *Larkspurs* will be available, and you might arrange these alternately with the *Penstemons* if you have enough. Take care that you keep all blue, mauve and allied shades well apart, whether at back or front, and work generally for colour contrasts. The *Shirley Poppies* will enable you to do this, particularly if you have them in separate colours. You should arrange the colours on a plan, with size of each group, prior to planting, though it is time the seeds of many were in the ground.

TREES AND SHRUBS.

SHRUBS FOR STONY SOIL (E. L.).—Shrubs such as *Berberis stenophylla*, *B. Darwinii*, *B. Aquifolium*, *Cistus laurifolius*, *C. monspeliensis*, *C. Loretti*, *C. ladaniferus*, *C. villosus*, *Brooms* in variety, particularly *Cytisus scoparius* and varieties *sulphureus* and *andreaeanus*, *C. albus*, *C. praeox*, *C. biflorus*, *Genista hispanica* and *G. virgata*, also *Tree Ivies*, *Olearia Haastii* and *Tamarix* in variety, may be expected to thrive. Place a little good soil about the roots at planting-time. *Rhododendrons* are not likely to do as well as the shrubs here mentioned.

THE GREENHOUSE.

PRIMULA OBCONICA LEAVES FOR INSPECTION (J. Mac).—The markings on the leaves of the *Primulas* are due either to red spider or to leaf-hoppers, we think possibly the latter, and if so, fumigation is called for. These insects are small, winged in their last stage, and run nimbly over the leaves. They are allied to the green flies and *Psylla*. Red spider can be kept down by spraying with water, so as to prevent the air from becoming too dry.

WHEN TO STOP CHRYSANTHEMUMS AND TAKE BUDS (Fresh Reader).—Hon. Mrs. Lopes, stop early in April, take first crown bud. W. Rawlings, stop late in May, first crown. Queenie Chandler, stop early in April and again the first week in June, second crown. Mrs. Gilbert Drabble, early propagated plants, stop in April and first week in June; later plants, natural break, first crown. Lady Talbot, stop early in May, first crown. D. B. Crane, stop early in April and on May 10, first crown in August. F. S. Vallis, stop early in April and middle of May. The remaining varieties in

your list should be allowed to make natural breaks and first crown buds taken.

ORCHID FOR NAME AND TREATMENT (E. S. Martin).—The name of the Orchid of which a flower-spike was sent is *Dendrobium speciosum*. It is a native of Australia, and was first introduced as long ago as 1823. Given suitable treatment, it should flower every year. The temperature of an intermediate house just meets its requirements—that is to say, a structure where in the winter the thermometer ranges from 55° to 65°, with a corresponding rise as the days lengthen. Such a place will suit most of the *Cattleyas*; in fact, it is often referred to as the *Cattleya-house*. This *Dendrobium* does best in baskets or pans, and when in a thriving state annual repotting is not necessary. When it needs repotting, it should be done soon after flowering and when the new growth is partially developed. A suitable compost for this *Dendrobium* is good fibrous peat or *Osmunda* fibre, with a fair sprinkling of sphagnum moss. If it does not need repotting, the plant is often benefited by taking away any of the old soil that can be so treated without unduly disturbing the roots, and top-dressing with some fresh material. From now onwards, if the plants are well furnished with roots, plenty of water must be given, while they will only need to be shaded from hot sunshine, a full light being very essential to their well-doing. By the end of July or thereabouts the growth will be completed, when the plants must be gradually inured to full sunshine and less water given. At that time they may be placed in a light, airy structure, but returned to the intermediate house before the nights get cold. As soon as the flower-spikes make their appearance, more water and a slightly higher temperature will be beneficial.

ROSE GARDEN.

GROWTHS ON ROSE ROOT (Puzzled, Sheffield).—The growths on the Rose root are the result of an attack of the bacillus of crown gall, *Bacillus tumefaciens*. This is present in the soil and invades roots, where it sets up irritation, resulting in the production of a large swelling. It is not at all clear whether this attack results in any real damage to the plants. We illustrated a remarkable example of it in our issue for December 12, 1914.

KITCHEN GARDEN.

CABBAGE PLANT FOR INSPECTION (Zielie).—The Cabbage is not attacked by the club-root disease, which is due to a fungus, but by the Cabbage gall weevil, a minute beetle which lays its eggs in the Cabbage stem. The egg hatches into a grub, which you may see on cutting open one of the swellings. The best way of avoiding future attacks will be to sprinkle sand moistened with paraffin along the rows of young plants.

CELERY DECAYING (Mercury).—The common cause of the rotting of Celery is the attack of a bacterium. No cure is known, and the only way to avoid the trouble is to choose the hardier varieties, especially the red ones.

MISCELLANEOUS.

GRUBS FOR IDENTIFICATION (Puzzled).—The grubs sent are the larvae of the two-winged fly called the St. Mark's fly, a red or black bodied, sluggish fly which appears in considerable numbers in gardens about St. Mark's Day. The grubs feed for the most part on decaying vegetable matter, and only when in great numbers damage roots. We suspect your soil is somewhat sour, and recommend you to give it a dressing of lime, after which, we think, you will not be troubled with these grubs.

GRUBS FOR NAMING (J. Fraser).—The grubs you send are dead, and not recognisable with certainty in their present condition. They are probably the caterpillars of the garden swift moth, which lays its eggs in the summer, and may be caught flitting at dusk over the beds in the garden. This is the best way to get rid of the pest. We do not think you have introduced it with plants.

POMPADOUR PRIMROSES AND MELONS (E. M. H.).—The Primrose should be taken out of the greenhouse before warm weather appears and be planted in rich soil in the coolest spot you can command. The shade of large trees would not be good for it, though shade from smaller subjects would be most helpful. Yes; give the plants liquid manure now, and in the open ground. Do not cut the roots in any way; cover them with rich soil or repot the plants deeply, and so cover the roots. You will find a frame facing south, with manure, the best for the Melons, or you could raise and cultivate them in the greenhouse. Raise the seedlings in a brisk heat of 70° or so, putting one seed in a 3-inch pot, but avoid watering if the soil is moist, as the seeds are liable to decay. The Melon requires a rather strong loam, made firm at planting-time, using a little well-decayed manure in the mixture. You had better raise the seedlings, and write us as to how and where you have decided to grow the plants, and we will give you a few hints for your further guidance.

PESTS FOR NAMING (T. H. Smith).—The creatures you send are very injurious to vegetation. They are, in fact, one of the most injurious pests which gardens, especially where the soil is sour, suffer from. Treatment with lime (using slaked lime now, but, better still, quicklime in the autumn) is one of the best measures to use against this spotted snake millipede, *Blanjulus guttulatus*, as it is called. It feeds on a great variety of different

things, and is especially fond of Lettuces, Potatoes and Peas just as they begin to germinate. Where only a few plants are to be protected, trapping with pieces of buried Potato is possible. Where many, the lime treatment (half a bushel to the square rod, about five and a-half bushels to your garden), constant cultivation and any treatment that will help to sweeten the soil are the methods to pursue. Some good may result by treating the soil with Vaporite, Apterite or some other soil fumigant.

NAMES OF PLANTS.—C. H. B.—1, *Lonicera fragrantissima*; 2, *Spiraea japonica*; 3, *Begonia manicata* var.; 4, *Peperomia argyreia*; 5, *Scilla sibirica alba*; 6, *Chionodoxa Luciliae*; 7, *Scilla sibirica*.—T. P.—1, Possibly *Sternbergia lutea*; 2, *Hippeastrum* variety; 3, *Vallota purpurea*. The bulbs are infested with mite. When badly attacked the bulbs should be burnt. A good remedy is to wash the bulbs with a solution of soft soap, sulphur, and soft water.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THERE were two outstanding features at the meeting held on March 30—the remarkable exhibit of *Dendrobiums* and other Orchids from J. Gurney Fowler, Esq., treasurer of the society, which attracted large numbers throughout the day; and the excellent grouping of *Crocuses* and *Daffodils*, garden fashion, on the floor of the hall, from Messrs. Carter and Co., Raynes Park, S.W. Each in its way was new—probably unique—demonstrating high-class and useful gardening respectively. At 2 p.m. the *Crocuses* had expanded their cups to the increased warmth and made a brave show. For the rest, there were alpinas and *Carnations* in plenty; and *Roses* from Mr. Prince of Oxford in great numbers—it was, however, a very comprehensive and beautiful exhibit, and the visitors revelled in the beauty of the flowers. *Darwin Tulips* in fibre from Messrs. Bath were also good. Messrs. Barr had the *Daffodil* board to themselves. Four novelties received awards.

FRUIT AND VEGETABLE COMMITTEE.

Present: A. H. Pearson, Esq. (chairman), and Messrs. J. Cheal, W. Bates, C. O. Walter, G. Kelf, A. W. Metcalfe, A. R. Allan, H. Markham, A. E. Humphreys, J. Davis, J. G. Weston, G. Reynolds, J. Jaques, A. Bullock, E. A. Bunyard, P. C. M. Veitch, Thomas Coomber, George Wythes, Owen Thomas, James Hudson and W. Poupert. The only exhibit of vegetables came from Mrs. E. H. Denison, Little Gaddesden, Berkhamsted (gardener, Mr. A. Gentle), and consisted of well-kept varieties of Potatoes, Leeks, Parsnips, Carrots, Turnips, Onions and other serviceable kinds. Of Potatoes alone some dozen or so varieties were staged in excellent condition. There were no exhibits of fruit staged.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Jeremiah Colman, Sir Harry J. Veitch, and Messrs. J. O'Brien, R. Brooman White, W. Bolton, Gurney Wilson, C. J. Lucas, S. W. Flory, Arthur Dye, J. E. Shill, W. H. Hatcher, J. Cypher, J. Charlesworth, Walter Cobb, T. Armstrong, F. M. Ogilvie, Pantia Ralli, R. G. Thwaites, F. Sander, R. A. Rolfe, J. Wilson Potter and F. J. Hanbury. J. Gurney Fowler, Esq., Pembury, Kent, received a gold medal for a collection of Orchids, which covered the western end of the hall. They were chiefly *Dendrobiums*, and of these, arranged against the wall as they might adorn the walls of a corridor, some 350 well-flowered examples were placed. In this way every plant—we might almost add every flower—was seen to advantage. It was, in all probability, the most comprehensive exhibit of this genus ever seen at a London show. A few kinds, as *D. nobile virginale*, were in plenty, others being represented by smaller numbers. That named was very pure and good. Others of note were *brymnerianum*, rich golden, with much-forked fringe; *chessingtonensis*, golden, dark centre; *imbriata oculata*, also golden, and fringed; *Armstrongia*, white, deeply coloured lip; *armstrongianum*, pale pink; *amenum*, signatum and a great variety of noble hybrids. A few *Odontoglossums*, *Cymbidiums* and *Cypripediums* were also shown.

Messrs. J. Cypher and Sons, Cheltenham, had good plants of *Epidendrum xanthinum*, E. x. Boundii, *Cymbidium Butterfly*, *Dendrobium Thwaitesii* Veitch's variety, and the white and pink flowered *Sarcophilus Fitzgeraldii*.

Sir Jeremiah Colman, Reigate, sent flowers of hybrid *Dendrobiums* and *Sophras* among others.

Mr. F. Menteith Ogilvie, Oxford, had about thirty well-flowered examples of *Dendrobium Thwaitesii* Veitch's variety, the rich golden, crimson-eyed flowers being very effective.

Messrs. Stuart Low and Co., Enfield, showed *Cattleyas*, *Laelias*, *Brasso-Cattleyas*, *Oncidium concolor*, *Miltonias* and *Dendrobium crassinode alba*. *Cattleya Schröderae alba* was very fine.

Messrs. J. and A. McBean, Cooksbridge, had a nice lot of *Cymbidiums*, *Odontoglossums*, *Masdevallias* and *Odontiodas*.

Mr. Harry Dixon, Wandsworth Common, displayed *Cypripediums*, *Cymbidiums* and *Odontoglossums* in variety.

Messrs. Charlesworth and Co., Hayward's Heath, had a glorious lot of *Odontoglossums*, among them many well-flowered examples of the pure white *O. crispum* *Xanthos*. O. Jasper, a particularly well-blotched

variety; two forms of *Odontioda Brewii*, very intensely coloured crimson; and the curious *O. Langowoyi*, dark sepals and white lip, were also in this group.

Messrs. Sander and Sons, St. Albans, had fine flowering examples of *Dendrobium wardianum giganteum*, *D. harveyanum* (golden flowers, heavily fringed), together with *Cymbidiums*, *Odontiodas*, *Miltonias*, *Odontoglossums* and *Cypripediums*. *Coccyne lawrenceana* was very distinct.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. E. A. Bowles, F. W. Harvey, W. J. Bean, J. W. Moorman, C. Blick, C. R. Fielder, J. F. McLeod, T. Stevenson, W. Howe, J. Jennings, W. Bain, J. Dickson, C. Dixon, C. E. Shea, C. E. Pearson, W. P. Thomson, E. H. Jenkins, G. Paul and R. Hooper Pearson.

Messrs. Carter and Co., Raynes Park, S.W., arranged a floor group of bedding Crocuses and Daffodils, occupying a double table length. The effect was very fine, in that it showed the better varieties of Crocuses as they should be seen massed in the garden. Some leading sorts were Royal Parks (white), Dorothea (pale violet) Purple Striped, White Striped and Triumph. In addition to the Crocuses were three circular groupings of Daffodils—a great central one of King Alfred, the two extremes of Sir Francis Drake. In all probability nothing finer of the former has ever been seen at this season, the rich golden colour and bold proportions of this unique variety appealing to all. Sir Francis Drake is paler in colour, though pleasing and artistic to a degree. It is also a handsome flower, and possesses a fine constitution.

Messrs. William Cutbush and Sons, Highgate, N., staged a very fine table of greenhouse flowering plants and shrubs, in which *Daphne indica*, *Azaleas* in variety, *Prunus*, *Cerasus*, *Wistaria sinensis*, *Azalea mollis* and other plants were well shown. In an alpine section were *Saxifraga Faldonside*, *S. burseriana*, *Iris reticulata*, *I. orchoides*, *I. warleyensis*, double blue *Hepaticas*, *Daphnes* and many others. Carnations, too, from this firm were very good, such as Mary Allwood, Carola, Salmon Winsor, Sunstar (yellow), Lady Ingestre (very fine pink), Mrs. L. Mackinnon (rich scarlet), Countess Fitzwilliam (rich crimson, new) and King George (rich scarlet, of Malmaison proportions) being among the best.

Messrs. Carter Page and Co., London Wall, E.C., exhibited *Violas* in pans, Yellow Beauty, Mrs. W. H. Woodgate, Marchioness (white), Snowflake and Stanley Saul (blue) being some good varieties.

Messrs. H. B. May and Sons, Edmonton, exhibited a floor group of greenhouse plants, in which we noted groups of *Azalea indica* in variety, *Genista racemosa*, *Boronia megastigma*, *Cinerarias* of an excellent strain, a fine lot of the dwarf-growing and useful *Calla alocasifolia*, together with Ferns, Palms and other plants. Two flowering groups of *Clematises* were also on view, such good varieties as Nellie Moser, Miss Bateman (white) and Fair Rosamund (blush) being among those shown. There were also some excellent *Amaryllids* staged.

Messrs. Barr and Sons, Covent Garden, had some charming bulbous flowers in a nice group. Of these, the gold and bronze *Tulipa chrysantha* appealed at once as much by its dwarfness as its grace and distinct colouring. Other good things were *Tulipa saxatilis*, *Narcissus juncifolius*, *N. triandrus*, *N. calathinus*, *N. King of Spain*, *N. Queen of Spain*, *Tulipa clusiana*, *Ranunculus montanus*, *Epigaea repens*, *Chionodoxas* and *Narcissus triandrus albus*. In addition, there were many charming *Saxifrages*, notably *Elizabethae* and *Haagei* (light and deep yellow respectively), *Erythroniums*, *Iris tingitana* and *Anemone blanda*.

Mr. F. Du Cane Godman, Horsham, showed half-a-dozen pans of *Tecophylaea cyanocrocus*, the whole beautifully flowered.

Messrs. Wills and Segar, South Kensington, had a lovely lot of greenhouse flowering plants, among which the spring-flowering *Heaths*, arranged in delightful groups, were most effective. Of these, the finer display was made by *Erica willmoreana*, whose rosy tubular flowers, in 18-inch long spikes, were highly attractive. Other good ones were *E. nivalis* and *E. Cavendishii* (yellow). In addition, the blue *Hydrangeas* were very fine, as were also big groups of white *Cyclamen*, *Boronia megastigma* and *Giant Mignonette*. Everything was most artistically arranged.

Miss C. Mangles, Seale, Farnham, showed half-a-dozen trusses of *Rhododendron eximium*, a very charming kind with short, campanulate flowers of rosy hue, which were most effective.

Messrs. Whitelegg and Page, Chislehurst, Kent, displayed alpine on rockwork with shrubs, *Daphne Cneorum* in profusion among the latter. Of alpine there were many *Saxifrages*, of which *Pauline*, *Elizabethae*, *apiculata* and *Faldonside* (all yellow sorts) were freely shown. *S. oppositifolia alba* was in good bloom.

Messrs. G. and A. Clark, Limited, Dover, showed a variety of *Polyanthuses* in many shades of colour, also a number of *Saxifrages* and other plants.

Messrs. Stuart Low and Co., Enfield, arranged a table of miscellaneous greenhouse plants and Carnations, the former including *Boronia*, *Crowea angustifolia*, *Erica melanthera*, *E. King Edward*, *Grevillea alpina* and other plants. The Carnations were in many varieties and in excellent condition. Mrs. C. F. Raphael (reddish scarlet), Marmion (scarlet and white), Geoffrey Henslow (a modified Marmion more brilliantly illuminated), British Triumph (crimson), Gorgeous (the finest cerise), Philadelphia (pink) and Snowstorm (white) were the best in a very good lot.

Mr. G. Reuthe, Keston, Kent, showed a great variety of alpine, of which the *Saxifrages* were the chief. Of these, *Saxifraga Kyrillii*, *S. Pauline*, *S. pungens*, *S. Faldonside*, *S. Haagei* and *S. Godseffii* are all yellow-flowered.

S. Grisebachii, *S. apiculata alba*, *S. marginata* (white) and *S. coriophylla* (white) were other notable sorts in the group. Lenten Roses were among other things.

Messrs. Allwood Brothers, Hayward's Heath, showed an excellent group of Carnations, of which Fairmount, Mary Allwood, Mrs. C. F. Raphael, Champion, Gorgeous, Terrific and Bishton Wonder were among the best.

Mr. L. R. Russell, Richmond, had a table of *Azaleas*, *Heaths*, *Wistaria* and other early forced shrubs.

Mr. Clarence Elliott, Stevenage, had a delightful rockery group, planting it with the choicest alpine. *Soldanella pusilla alba*, *Saxifraga Obstritii*, *Androsace Lageri*, *Saxifraga illicina*, *S. marginata*, *S. oppositifolia latina* (rosy), *S. scardica obtusa*, *S. Sundermannii*, *Draba imbricata* (yellow), *Anemone vernalis* and *Saxifraga Paulinae* (yellow) being among the more beautiful.

Mr. George Prince, Oxford, had a lovely lot of Roses. Rayon d'Or, Mme. Edouard Herriot, Countess of Gosford, Richmond, Josephine Nicholson (pink), Molly S. Crawford (white), Irish Elegance, Harrisoni, Juliet, Lady Hillingdon, Austrian Yellow and Lady Plymouth (yellow) were a few of the gems with which the group teemed.

The Misses Hopkins, Shepperton-on-Thames, had a select lot of early spring flowers, of which *Narcissus capax flore pleno*, *Shortia galacifolia*, *Hepaticas*, *Primula frondosa*, hardy *Heaths* and double *Primroses* were noted.

Mr. G. W. Miller, Wisbech, again showed boxes of *Daisies*, *Primroses*, *Pansies* and other early hardy flowers.

Mr. James Box, Lindfield, Sussex, showed *Primula Julig*, *Erythronium Hartwegii*, *E. Hendersonii*, *Stylophorum diphylum*, *Shortia galacifolia*, *Primula marginata*, *Trillium rivale*, *Iris orchoides*, *Erythronium nuttallianum* (yellow) and double blue *Hepaticas*, all in excellent condition.

Messrs. W. Wells, Merstham, showed Carnations very finely. Pink Sensation was grand, both in size and colour. Other good ones were Mrs. G. Lloyd Wigg (white), Aviator and Champion (scarlet), Yellow Stone and White Wonder.

Messrs. Piper, Bayswater, set up a remarkable exhibit of forced shrubs and flowering trees, many, as *Crataegus*, *Pyrus* and others, in fan-trained specimens. *Azaleas*, *Wistaria*, *Cytisus andreanus prostrata* and *Rhododendrons* were among those noted.

Lady Paget, Warren House, Kingston Hill, showed a group of *Star Cinerarias* in a great variety of colours. The plants were admirably flowered and nicely arranged.

Mr. Maurice Prichard, Christchurch, had a delightful lot of pot-grown *Saxifrages*, of which *apiculata*, *marginata*, *Petrashii*, *Paulinae* and *Kotschyi* were the choicest. *S. rocheliana lutea* was among rare sorts. The *Shortia* was very fine.

Messrs. R. H. Bath, Limited, Wisbech, had a glorious lot of Darwin *Tulips* in fibre, all the kinds being shown in perfection. Pride of Haarlem (cherry), Sierrard van Flora (rosy), William Copland (heliotrope), Philippe de Comminet (very dark), Angelica (also dark), Maiden's Blush, Bartigon (scarlet) and Isis (bright scarlet) were among the best. The *Chionodoxas* were very beautiful.

Mr. H. Burnett, Guernsey, had, as usual, a very fine display of Carnations, of which Mrs. W. B. Clode (very strongly scented), Salmon Enchantress, Enchantress Supreme, Marmion (scarlet and white, fragrant), Mrs. C. F. Raphael, Mikado, Mary Allwood, R. F. Felton, Champion and White Wonder were very fine.

Mrs. E. H. Denison, Little Gaddesden, Berkhamsted, showed some charming vases of *Acacia cultriformis* and *Rose Fortune's Yellow*. The former were very daintily arranged, and the plant is pleasing withal.

Messrs. Young and Co., Cheltenham, showed Carnations, Triumph, Philadelphia, Mikado, Britannia, May Day, Mary Allwood, Rose Enchantress and Duchess of Devonshire being the more prominent.

Robert Sydenham, Limited, Birmingham, had a group of *Tulips*, *Freessias*, *Lily of the Valley*, *Spiraeas* and *Daffodils* growing in bowls.

WARGRAVE GARDENERS' ASSOCIATION.

On March 24 a very interesting and useful paper on the "Early Flowering Bulbous Iris" was given by Mr. P. Wiseman of Messrs. Waterer, Sons and Crisp's Hardy Plant Nurseries. He referred more particularly to the Juno and Cushion varieties, giving directions for planting, the kind of soil best suited to their requirements, and the best means of obtaining good flowers. A good discussion followed, and many questions were answered by Mr. Wiseman, who received the best thanks of the members for his paper. Messrs. Waterer, Sons and Crisp exhibited a splendid collection of May-flowering *Tulips* in pots, and were heartily thanked for so doing; while Mr. W. Pope was awarded a cultural certificate for finely flowered specimens of *Dendrobium wardianum*. Mr. W. Bazeley showed living specimens of the Black Currant mite under the microscope.

READING GARDENERS' ASSOCIATION.

At the fortnightly meeting of this association, held at the University College on Monday evening, the 29th ult., Mr. H. Goodger, chairman of the committee, was the speaker, and his subject, "A Few Useful Vegetables." Mr. Goodger is one of the most successful growers in the district, and having regard to the importance of the vegetable crop at this time of war, his remarks were followed with great attention. The best methods to produce the finest Potatoes, Peas, Beans, Leeks, Onions, Carrots, Parsnips, Beet, Celery, &c., both for the home as well as the exhibition table, were given in the most able manner, and a profitable discussion followed the lecture.

The points competition resulted as follows: Mr. F. Townsend, 12 (full points) for *Primula malacoides*; Mr.

E. Blackwell, 12 (full points) for *Violet Marie Louise*; Mr. H. Goodger, 9 for Broccoli Sutton's Safeguard Protecting. Mr. G. E. Hawes exhibited two dishes of fine Ailsa Craig Onion.

Razors Wanted for Our Soldiers.—Mr. W. H.

Ellis, Master Cutler, Cutlers' Hall, Sheffield, has been asked by the War Office to collect razors from private persons who have no further use for them, so that they may be made serviceable and sent to our soldiers on active service. Although 25,000 have already been collected in this way, there is need for many more, as it is impossible to obtain sufficient new ones. Those of our readers who have razors for which they have no further use should send them direct to Mr. Ellis at the address given.

Royal Caledonian Horticultural Society.—

This society has just issued the schedule of its spring and autumn shows, to be held respectively on April 28 and 29, and September 8 and 9. The competitions provide the usual features which have made the society's shows of such importance, and should lead to splendid exhibitions of flowers, fruit and vegetables. At the autumn show the probable centre of interest will be the competition for the Thomson Challenge Trophy for Grapes, value fifty guineas, presented by Messrs. William Thomson and Sons, Tweed Vineyards, Clovenfords, and to be won three times before becoming the property of the winner. The society has also issued a list of the books belonging to it, which members may consult on application to the secretary.

The Perpetual-Flowering Carnation Society.—

The schedule relating to the Perpetual-flowering Carnation Society's show, to be held at Leeds on April 29 and 30, is to hand, and we observe that the exhibition is to be held in conjunction with the North of England Horticultural Society. Special classes have been arranged for gardeners and amateurs residing north of the Trent, and several of the North of England Horticultural Society's challenge cups are being offered, in addition to the formidable number controlled by the Perpetual-flowering Carnation Society. Schedules may be obtained from the secretary, Mr. T. A. Weston, Orpington, Kent.

Gardeners' Wages in Edinburgh.—

At a recent meeting of nurserymen in Edinburgh it was arranged to raise the charges for gardeners sent out to work by the day, and also to advance the wages to the men employed. The advance is at the rate of 1d. per hour, and at a subsequent meeting of gardeners satisfaction was expressed at this advance. An effort is being made to induce smaller employers who have not fallen into line to concede the rise also.

OBITUARY.

THOMAS HUGHES.

With great regret Messrs. Young and Co. notify us of the death of Mr. Thomas Hughes of Cheltenham, their much respected foreman. Mr. Hughes was taken suddenly ill on Wednesday, March 24, while at his work at Messrs. Young's Carnation Nurseries at Hatherley, Cheltenham. Deceased, who was well known by exhibitors, had been in Messrs. Young's employ for many years, and was much esteemed by his employers and respected by those with whom his daily duties brought him in contact.

THE GARDEN.

No. 2265.—VOL. LXXIX.

APRIL 17, 1915.

NOTES OF THE WEEK.

Horticulture at the Royal Agricultural Society's Show.—We are pleased to see that there is to be an extensive horticultural section in connection with the Royal Agricultural Society's Show to be held in Nottingham from Tuesday, June 29, to Friday, July 2. The schedule is now ready, and copies can be obtained from the secretary, Mr. Thomas McRow, 16, Bedford Square, London, W.C.

An Attractive Ranunculus.—Although the lesser Celandine (*Ranunculus Ficaria*) is quite common in most places, the same cannot be said of the variety major, sometimes known as *Ficaria vandykeana*, for it well deserves a place in the wild garden. For some weeks it has been pushing forth its large, golden yellow flowers, and will continue for some time to come. When mixed with *Chionodoxa*, as we saw it the other day, with the sun shining on it and the *Ranunculus* flowers wide open, they were very effective.

The Double-Flowered Blackthorn.—Now that the Blackthorn, or Sloe, is flowering freely in our hedgerows, it may be of interest to draw attention to the double-flowered variety, known by the botanical name of *Prunus spinosa flore pleno*. This makes a graceful, low-spreading tree that is pleasing to behold at all times, but just now, when the black-barked branches are wreathed in faint, rosette-like flowers of the purest white, it will pass muster with the choicest of our hardy flowering shrubs or trees. Planted in the woodland, where it can have a background of dark-leaved evergreens, this double-flowered Blackthorn is particularly effective.

Flower Shows and Horticulture in America.—Under the heading of "Societies," on page 192, we publish a report, by Mr. J. Harrison Dick, editor of the *Florist's Exchange*, of a large floral exhibition held in New York from March 17 to March 23. We think this report is of more than ordinary interest, inasmuch as it reveals in no small degree the influence that British gardeners are exercising on horticulture in the United States. We doubt if European horticulturists realise fully the wonderful strides that are being made by our American cousins. Until comparatively recently,

horticulture, as we know it at home, was but little understood by them; but signs are not wanting that they are making strenuous efforts to understand the art of private gardening and European methods of exhibiting.

The Pasque-Flower.—Of the genus *Anemone* few species are more highly prized by lovers of hardy plants than the Pasque-flower (*A. Pulsatilla*). Although a native of Britain, it is not often found in a wild state, but in our gardens it is one of the most pleasing flowers of the spring. The Pasque-flower is never seen to better advantage than when planted in colonies, preferably in the semi-

prove normal, the early flowering section will be at its best towards the end of the present month, and the other sections during the first fortnight in May. In order to facilitate the inspection of the trial, an interleaved index has been prepared in pamphlet form. Fellows of the society visiting Wisley may obtain copies of this index free of charge on application at the office. The gardens at Wisley are situated about $3\frac{1}{2}$ miles from Byfleet, $3\frac{1}{2}$ miles from Horsley, and $5\frac{1}{2}$ miles from Weybridge, all stations on the London and South-Western Railway, with frequent trains from Waterloo and Clapham Junction.

New Zealand Spinach.

Where one has difficulty in keeping up a constant supply of ordinary Summer Spinach in hot weather, the New Zealand kind will supply that want. In Northern gardens it will be advisable to sow the seed indoors, prick out the seedlings into small pots when ready, and harden off for planting outdoors in May. In Southern parts it can be sown outdoors about the second week of that month. If given ample room between the plants, it is really astonishing what a picking one can get from a small plantation. Seed should be ordered now.

Open-air Treatment for

Wounds.—Those who appreciate open-air life—and, we presume, all who are interested in gardening do—will be interested in a letter by Dr. H. S. Souttar that appeared in last week's issue of *Country Life*. Dr. Souttar has

A COLONY OF THE PASQUE FLOWER (*ANEMONE PULSATILLA*). ALTHOUGH A NATIVE OF BRITAIN IT IS NOT OFTEN FOUND IN A WILD STATE

wild parts of the garden, where its lavender violet flowers, each with its silken ruff, can thrust themselves up between the russet fronds of hardy Ferns. There are several varieties, one with rose-coloured flowers and another with blossoms of lilac hue, while a more rare plant has petals of almost chocolate colour. This *Anemone* appreciates well-drained soil of a calcareous nature, and for that reason is often grown in the rock garden, where the natural soil in other parts of the grounds is too heavy.

Trial of Tulips at Wisley.—The trial of Tulips which is being continued this year in the Royal Horticultural Society's Gardens at Wisley includes about 5,000 stocks. Should weather conditions

had considerable experience of wounds in the Belgian Field Hospital, close to the Front, where the wounded men came direct from the trenches, and where only the very worst cases were treated. It was found that septic wounds became much worse when treated with the ordinary dressings, but when the patients were put out in the courtyard, as, it was thought, to die, the wounds quickly became clean and inoffensive, and the patients made rapid recovery. Dr. Souttar states that the bacteria which cause sepsis cannot live when exposed to the air, hence the good results that were obtained. His letter is of national importance at the present time; therefore we make no apology for referring to it.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Cherokee Rose in Scotland.—*Rosa lævigata* has been flowering well this spring in the conservatory at St. Mary's Isle, Kirkcudbright, where it is grown up the roof. It is also successfully cultivated there against a warm wall in the open, where it blooms and usually stands the winters well, as St. Mary's Isle has a mild climate for the district. The Cherokee Rose is not too well known, and would be appreciated by many who take pleasure in single blooms. The handsome flowers are of a good white, are large, of good substance, and look exquisite with the contrast between the yellow stamens and the white petals. It lasts longer as a cut flower than do many of its sister Roses with single blooms.—A.

The Genus Grevillea.—There is an evident omission from Mr. Morbey's communication on

Forsythia intermedia spectabilis.—This charming Forsythia, which was given an award of merit at the meeting of the Royal Horticultural Society on March 30, and is illustrated on page 176 of THE GARDEN, deserves to be better known. It is now some years since it was distributed, and though stocked in many nurseries that make a speciality of hardy shrubs, it is not generally met with. *F. intermedia* itself is a hybrid between the two old species, namely, *F. suspensa* and *F. viridissima*. In general appearance it is about midway between the two, combining the exceeding floriferousness of *F. suspensa* with the bushy habit of *F. viridissima*. Since *F. intermedia* was distributed, some three or four forms thereof have been put into commerce. Of them *spectabilis* is remarkable for the rich yellow colour of its blossoms and the profusion in which they are borne. In any selection of flowering shrubs, however limited, this Forsythia is, I consider, fully entitled to a place. Like the other members of the genus, it is not at all difficult of increase,

plants are such delightful and uncommon shrubs—they are yet so rare in gardens—that all the plants it is possible to secure should be grown. The *Stachyurus* belong to the Natural Order Ternstroemiaceæ, and are deciduous shrubs about 3 feet in height. The pale yellow flowers are borne in pendent, catkin-like inflorescences towards the ends of the shoots of the previous season's growth. The buds form in the axils of the leaves in autumn and during winter they may be noticed developing gradually. The flowers open during February and March, in advance of the leaves. In describing *S. chinensis* as distinct from *S. præcox*, botanists denote broader and crenately serrate leaves abruptly contracted into a long acumen, a difference in the colour of the young wood, a longer style and smaller fruits. The *Stachyurus* require a warm, sheltered position from the east, and light, well-drained soil, consisting of sandy loam and peat or leaf-mould.—H. O.

The Bardfield Oxlip.—I was very interested in the excellent article on this flower in your issue of March 27, page 152. I have several plants, collected in the Bardfield district a few years ago, flowering in a cool corner of my garden just now, and feel sure that other readers would grow it, could plants be easily obtained.—A. B. ESSEX.

Rock Gardening as Represented by Its Votaries.—I have read with immense interest the recent articles on the inmates of rock gardens for I had formed a fancy to make a rock garden with the sandstone found in parts of my garden that is to be, within my "hedge of sorts" (now planted). But oh! on reading the said discourse I am disillusioned, and do not want one at all. For from what I read it seems that a rock garden should be a sort of invalid home for feeble foreigners chiefly. No natives need apply for a place unless they are "miffy." Nothing but plants which need continual coddling, shading and sheltering, fussing and feeding with special food in the way of soil may be admitted. Any plants which thrive without special attention, or—worst crime of all—actually dare to spread and increase, must immediately be banished, or at best be "cribbed, cabined and confined" in tin tubes or starved in stone cylinders. Now, this is the very reverse of my ideal in a garden. I love to see my flowers look happy and healthy, as if they enjoy growing in my garden. I would as soon keep a puny, pining, homesick child in my house as these poor prisoners of the cruelly kind rock gardeners. They bring to my memory a certain clump of Parsley Fern I once captured on the slopes of Conistone Old Man and brought home in triumph to my mother, who cherished a choice collection of British Ferns. In spite of every care, the poor thing gradually became more and more sallow and sickly, and eventually wilted and withered away. Every time I looked at it I felt myself a murderess. No; I will not have a rock garden. My flowers shall freely grow and blow at their own sweet will, and any that do not thrive shall be sent to some more congenial climate.—ANNE AMATEUR.

Prospect of the Apple Crop.—Although last year was remarkable for the heavy crop of Apples and the quality of the fruit, the trees here have again a most promising appearance for a full show of blossom; indeed, I never saw them looking better. Where all are so good, it is difficult to specialise. Lane's Prince Albert, which cropped thinly last year, is very thickly studded with fruit-buds. Some six-year grafted trees of Norfolk Beauty and some five-year grafted tree

FLOWERING SHOOTS OF A NEW HARDY SHRUB, STACHYURUS CHINENSIS.

Grevillea on page 170. As it stands, he is made to state that there are fifty-seven varieties of Grevillea in Australia instead of 157 species. I substitute the latter denomination as the correct one in this connection. Grevillea, as well as Acacia and Eucalyptus, is a characteristic element in the vegetation of all parts of Australia, including one species, at least, very common in Tasmania. A few species occur in New Caledonia, but the genus does not extend to New Zealand. The number of species described in Bentham's "Flora Australiensis" of forty-five years ago is 156; but that has been increased by the discovery of additional new species. The species of Grevillea vary in stature from trailing, prostrate shrubs to trees 100 feet in height. Many of them have very brilliantly coloured flowers, and are conspicuous objects in the scenery when in flower.—W. BOTTING HEMSLEY.

as cuttings of the growing shoots taken in the summer, dibbled into pots of sandy soil, and placed in a frame which is kept close and shaded, will soon root.—H. P.

A New Chinese Shrub.—*Stachyurus chinensis* is a new species or variety of *Stachyurus* noted by several Chinese collectors and introduced by Mr. E. H. Wilson, who sent home seeds. These have germinated well, and the plants are growing and flowering freely. In a bed of seedlings the habit of growth varies, some of the plants being quite upright, while in others the shoots are spreading. A curious feature of one plant is that when the racemes are developing they are upright, but before the flowers open they assume the usual pendent habit. Whether the Chinese *Stachyurus* is sufficiently distinct from the Japanese *S. præcox* to be given specific rank we must leave the botanists to decide. Both

of James Grieve show much promise of fruit. Bramley's Seedling, although it carried enormous crops last year, again gives much promise. Trees of Mank's Codlin on their own roots are thickly budded with fruit-buds, and so are the trees of Cox's Orange Pippin.—E. M., *Swanmore, Hants.*

Magnolia stellata.—I was much interested in the note by "W. F." and the beautiful illustration of a plant in bloom on pages 150 and 151, issue March 27. The position for effect is ideal. I have grown Magnolias for many years on a large scale, carrying on the work of other cultivators, and some of the trees of *M. grandiflora* resembled Oaks, measuring more than 15 inches through the stem and being 25 feet and over in height. There were many young trees and others of medium size in good variety, and growing in naturally dry and very moist soils without apparent difference to the health of the trees. In my case *M. stellata* was marred by late frosts in exposed positions; but one large tree, several feet higher than that mentioned by "W. F.," growing on the north side of a very high wall—as a standard or bush and not trained to the wall—flowered late, and even when frosts came the lovely blossoms were rarely damaged by them.—G. G.

Two Good New Potatoes.—I was interested to read the note about the new Potato Prosperity by "H." in your issue for March 13, page 128, and can endorse all that he says about its excellent cropping and keeping qualities, and also its flavour. It may interest readers to hear of two other good new varieties that I tried last year with considerable success. These came from Mr. W. E. Sands, Hillsborough, County Down, Ireland, and were named, respectively, Mayflower and King George V. The first is a very early Potato and a heavy cropper, the tubers being pebbled, shaped, with white, beautifully netted skins. Planted at the same time as Midlothian Early, the roots were ready for digging ten days before that variety. King George V. is a second-early or midseason Potato, the large, oval tubers coming of good shape and with shallow eyes. The flavour and cooking qualities were excellent, and I feel sure both these Potatoes have come to stay.—A. B. ESSEX.

What is Wanted in Daffodils.—A very desirable thing for Daffodil raisers to work for seems to be the production of giant yellow incomparabilis. Of Giant Leedsis we now have an excellent and ever-growing selection—I mean things of the Lord Kitchener type. But flowers of a class such as, for instance, a magnified Homespun, though badly wanted, do not appear to be forthcoming. A batch of seedlings from a cross made here between King Alfred (seed) and Homespun (pollen) is now in bud for the first time, and should yield something useful; but very likely, after all, the particular thing that I am craving for will turn up as one of the results of a totally different cross—such are the vagaries of seedling raising. If there is in existence a flower of the calibre and proportions of Great Warley, but with more refinement and a greater length of stem, and self yellow, I have not yet seen it; but possibly someone else may have done so—Mr. Jacob, for instance, who is a perfect mine of information on the Daffodil. In any case, it seems to me to be a thing that will fill a gap, and be welcomed by all keen Daffodillers.—ORNATUS.

Colour Charts: What is Wanted.—The Rev. Joseph Jacob, in his article on the above in *THE GARDEN* of March 6, page 116, brings to notice a matter of much importance. There

are several good reasons why the shades of colour in flowers should be standardised, and not the least weighty of these is the benefit that would accrue to prospective buyers of plants and seeds when scanning the lists of nurserymen and seedsmen. As things are at present, if you stick religiously to one list, you will meet with many surprises (if you purchase) and not a few disappointments; and if you consult and compare several lists, the result will be "confusion worse confounded." Take the following examples of descriptions from leading firms, chosen at random. Sweet Pea Charles Foster: (1) "Combination of mauve and pink"; (2) "Metallic opal pink"; (3) "Hydrangea pink, suffused pale mauve." Or Rose Marquise de Sinety: (1) "Roman ochre, shaded fiery red"; (2) "Golden yellow, shaded bronze red." Keeness of perception in distinguishing between shades of colour is a natural gift, and perhaps not a very common one; therefore there are, I think, thousands of flower-lovers who would hail with gladness a well-arranged colour chart, produced in pocket-size book form, and to be sold at a popular price. Of course, when hundreds of shades have to be described, it puts a fairly heavy tax on one's vocabulary, but such descriptions as "Hermosa pink," "Isabel yellow" and "Nelson pink" should be avoided.—CHARLES COMFORT.

The Celery Fly.—As a reader of *THE GARDEN* I am writing to tell you of a method I adopted with the Celery fly last year and in 1913. Like many others, we were troubled with it season after season, and our plants were made wrecks in spite of soot dustings and crushing the maggot in the leaf, a slow and tedious affair when badly attacked. In 1913, after the fly had begun its work and the plants were looking rather bad, the thought occurred to me, while passing down the rows for maggot, to catch the fly, and this is done by drawing the open hand quite close to the fly when settled on the foliage, and with a quick sweeping movement and closing it again most of the flies are caught after a little practice. In the first season after adopting this plan, for the first few days we caught from sixty to eighty flies, for several more days fifty to sixty flies, and by the end of a fortnight or so we seldom saw more than half-a-dozen on any day. After this we could detect a great difference in the newer foliage, which was comparatively free from maggot. As the pest generally commences its attacks early in August, and as we did not put the new plan into use till September, I quite believe it would have kept the plants from the bad state into which they had become if we had started when the pest did; but the idea had not then occurred to me. Last year I was on the look-out early for the flies, but there were very few to be seen compared with 1913, and I caught what I could and crushed what maggots there were. I may say that I never had cleaner Celery when it was earthed up. Perhaps the small number of flies seen in 1914 compared with the previous year was due to killing the flies and maggots. I generally go over the rows of plants each day, spending a few minutes crushing the maggots, and while one is doing this it takes no more time to catch the flies. As there are several broods in a season, it is certain there will be no more from the flies that are caught. As no insecticide is of use, as in the case of sucking insects, I think it is better to get rid of the flies, as far as possible, in the way I have stated. Perhaps you may think this of some use.—E. COPE.

QUALITY IN VEGETABLES.

MY mind being rather filled at present with the following grievance, I am hoping you will let it be ventilated in *THE GARDEN*, so that perhaps something may come of it. There must be many who, as the advertisements put it, are only "two in family," and no matter how many servants are kept, if only one of the two in the dining-room eats vegetables, the problem is always how, in these days of enormous kinds, to have ones that either do not form a dish looking enough for a large family, or an equally absurdly small one of, say, four or five (gigantic) Brussels Sprouts, &c., for it is a sad fact that the smaller and more refined-looking vegetables are now only mentioned in small print, and seldom, if ever, sent out in the guinea or other "collections," which are in themselves so convenient and so amply sufficient for small households. One is, therefore, forced to eat Broad Beans the size of kidneys, Brussels Sprouts like large Walnuts, Salsify, one stick of which is enough for a helping, Cauliflowers that no woman could tackle alone, and so on (even the Parsley having become almost a shrub), all of which varieties have the recommendation (?) of "Exhibition," "Prize," "Giant," "Mammoth," "Leviathan," &c., attached to them.

Surely the perpetual shows and consequent competitions for medals, certificates, &c., are creating a class of vegetable which is becoming nothing less than a nuisance for private growers. No one *really* cares to eat these gigantic vegetables, which hold the water of our English cooking, look ungainly and coarse on a dish, take up a great deal of room on one's plate, and are never as sweet-tasting as the smaller kinds. I would rather go without puddings than vegetables, growing every unusual kind, and to my mind Broad Beans cannot be small enough. They should be first picked when no larger than Marrowfat Peas, and the supply for the dining-room should stop when they are the size of Filberts, otherwise they are tasteless and woolly. Brussels Sprouts, too, cannot be too small, only the "Gem" varieties being grown both of these and the Broad Beans; Carrots also, and so on, to ensure which I have always endeavoured, when ordering a collection, to get besides some of the daintier "breeds" of items I know will be sent as exhibition varieties, thus paying twice over, perforce.

If these must be grown—and till competition at shows for size ceases they will be—could not seedsmen try the experiment of sending out some collections of seeds of small varieties of vegetables of a high quality for people who want plenty of every sort, but ones that will furnish them, if they live alone, with small, dainty dishes, instead of the either mountainous heaps or equally absurd three or four Sprouts, &c., considered from motives of economy to be enough for the one person by the autocrat in the kitchen? A. LA T.

FORTHCOMING EVENTS.

April 20.—Lincolnshire Spring Show at Spilsby.

April 21.—Midland Daffodil Society's Show at Edgbaston Botanic Gardens, Birmingham (two days).

April 22.—Eastwood Continuation Schools Glasgow. Lecture by Mr. John Smellie on "Pansies and Chrysanthemums," at 8 p.m.

April 24.—Presteign Spring Show.

THE DIANTHUSES OR PINKS.

NOTWITHSTANDING the fact that considerable confusion exists in the nomenclature of the Dianthuscs, or Pinks, they form one of the most interesting and pleasing families of hardy plants that we know. Members of the genus have been grown in English gardens from very remote times, and the day is far distant when the fragrant florists' Pinks will fail to interest those who appreciate quiet beauty and old-world fragrance. In an article of this kind it is impossible to do more than briefly touch on a few of the most important; in the Carnation itself—a member of the Pink family—there is material sufficient to make a large book, and one has only to call to mind the lovely Malmaison Carnations, the border varieties

are now a great many hybrids in existence, some of which are very charming, and at Friar Park Sir Frank Crisp has raised quite a host, which have yet, I believe, to be named. The following are all good:

Dianthus arenarius.—This is commonly known as the Sand Pink. It makes a neat tuft of very narrow, grass-like foliage of bright green colour. The flowers are borne in June and July on slender stems 6 inches to 9 inches high, and are much fimbriated at the edges. On most plants they are white, but in some instances blush or pale lilac blossoms are produced.

D. cæsius.—This is the Cheddar Pink, and is one of the most beautiful of all our native flowers. The plant forms a dense, spreading tuft of slightly glaucous foliage, and produces its flowers on stems about six inches high. The blossoms are bright rose pink in colour, and usually open during the early part of June. It loves a crevice in the rocks and a little old mortar in the soil.

colour, and are borne on branching stems a foot high. There are a great many varieties, however, one of the best being Duchess of Fife. If raised from seed, considerable variation will be found in the plants.

D. superbus.—In appearance the foliage of this Pink reminds one of a miniature Sweet William. The flowers, which open from May to August, are variable in colour, generally, however, showing rose or pale pink tints. The petals are very long and deeply fimbriated. It is not difficult to grow, but should be treated as a biennial, new plants being raised from seed one year, to flower the next. It is really more curious than beautiful.

D. neglectus.—In some gardens this charming Pink is difficult to grow, but in others it seems to thrive without any special attention. Evidently it appreciates peat and good loam as a rooting medium, with copious supplies of water during hot weather. It has neat, grass-like foliage, and the flowers open during May and June on stems 4 inches to 6 inches high. These are bright carmine in colour, and when well grown the plant is a gem for the rock garden.

D. Spencer Bickham.—This is a very beautiful garden hybrid, raised, I believe, by crossing the Cheddar with the Maiden Pink. It is much like the first named in habit, but the rather large flowers are brilliant, glowing rose colour. Its blossoms very freely in June, and ought to be grown wherever Pinks are appreciated.

Although border Pinks scarcely come within the scope of this article, one cannot let the opportunity pass without mentioning a variety named Gloriosa. This was put into commerce three or four years ago, and is the best all-round garden Pink that I know. It has flowers as large and as fragrant as the well-known Mrs. Sinkins, but they are bright rose pink in colour, and do not split their calyces as do the blooms of that variety. Moreover, it commences to flower at the end of May and continues until well into July, a trait that I have not yet found in any other Pink. H.

GLADIOLI FOR SPRING PLANTING.

DURING the late summer and autumn months, from mid-July until well into October, there is usually a heavy demand for bold, brilliant-coloured flowers for cutting, and few plants will give such a wealth of material for so comparatively small an outlay of time and trouble as the large-flowered, modern Gladioli. Time was when these flowers found a home in but few gardens in the country, a fact that was largely due to the paucity of really good colours among them, and to an erroneous but widespread belief that they were tender plants and very difficult to grow really well. Hybridists, with their usual acumen, have during the last two decades given us a wonderful wealth of new colours, principally by crossing the different species or types, and, in addition, have imparted to the plants increased vigour and to the flowers greater size and graceful poise, so that the modern Gladioli are flowers that should be grown on a bountiful scale in all good gardens, and especially those where autumn flowers are appreciated.

Of the stately bearing of these Gladioli in bed or border it is not necessary to comment at length.

DIANTHUS PLUMARIUS, A FREE-FLOWERING AND FRAGRANT PINK.

and the newer, but none the less pleasing, Perpetual-flowering type to realise what vast ramifications exist. For that reason it is only proposed to deal here with a few of the best of the dwarf-growing kinds—those specially adapted for the rock garden or for forming edgings to beds or borders.

In a broad sense these dwarf Pinks are not difficult to grow. Some there are, it is true—such, for instance, as the Glacier Pink (*Dianthus glacialis*) and the Alpine Pink (*D. alpinus*)—that call for a considerable amount of cultural skill, but these are plants only for the connoisseur. There are plenty of good ones available that grow easily and flower freely. What they need is rather porous soil that is not over-rich, and in most cases a sunny position. Most of those named here are easily propagated by means of cuttings or pipings taken off during July and planted in very sandy soil in a shady place, or even a cold frame. Some of the species are also easily raised from seeds, sown preferably early in spring in a cold or slightly heated frame. There

D. deltoides.—Another native of Great Britain, and known as the Maiden Pink. It has very small, green, grass-like foliage, which forms a dense tuft, whence spring the lovely deep bright rose pink blossoms on slender stems about nine inches high. There are several varieties of it, notably albus, with white flowers, and superbus, with larger blossoms.

D. fragrans.—Although its specific name implies that this has fragrant flowers, I have never yet been able to detect sufficient scent to be worth mentioning. It is a useful and easily grown Pink, however, its much fimbriated white flowers being produced in abundance during June and July from good-sized tufts of narrow, green foliage.

D. plumarius.—This is the wild form of our fragrant garden Pinks, and is a splendid plant for the bolder parts of the rock garden. It is easily grown, and quickly makes a large tuft of glaucous foliage. The flowers, which open in June, are usually of a rather pale pink

A SEEDLING PINK WITH HEAVILY FRINGED PETALS.

Flower-spikes 3 feet or even more in height, clothed for at least a third of their length with large, fully opened and gloriously brilliant blossoms, the middle tier carrying a wealth of partly opened flowers, and higher up neatly folded buds in their pale green sheaths, need only to be once seen to be fully appreciated, and it is difficult to think of a position in either large bed or mixed border where they would be out of place. Grouped in colonies of nine or more, according to the size of the border, they are ideal for growing with herbaceous flowers, and can be planted in close proximity to some that flower early in the summer and so fill the hiatus that would otherwise occur. One of the prettiest combinations of Gladioli and herbaceous plants I have ever seen was a large bed sparsely planted with the white Phlox Mrs. E. H. Jenkins, and the scarlet *Gladiolus brenchleyensis* freely interspersed among them. Both flowered in August, and the combination of pure white and scarlet was particularly good.

Although these Gladioli are such excellent and useful plants for creating brilliant effects in the outdoor garden, I think they are even more useful for cutting, a point in their favour that was briefly referred to at the outset. The reason is this. The flowers on a spike, as already stated, do not all open at one time, the lower ones unfolding first, to be followed later, and in stages, by the buds on the upper portion of the stem. This development of blossoms goes on equally well when the spikes are cut and placed in water as if they are allowed to remain on the plant; consequently flower-spikes which are cut in their early stages of development will last in good condition in water for ten days or a fortnight, removal of the lower flowers as they fade and the replenishing of water every other day being all the attention that is necessary.

Now that the planting season is here, it may be useful to give a few hints on the cultivation of these flowers, which play as important a part in the autumn garden as the stately Darwin Tulips do in that of the spring. Fortunately, they are

not very difficult to manage, and providing good corms, as the bulb-like roots are technically called, are procured, they can be accommodated in almost any garden in the United Kingdom. There are, however, a few essential points that must be remembered. These plants must have an open position, *i.e.*, one not heavily shaded by trees or buildings; well-drained, moderately rich soil; and the corms must at planting-time be kept from actual contact with fresh or green manure. With a modicum of ingenuity these essentials can be provided in almost any garden. Providing

the soil has been deeply dug, and manured deep down with thoroughly rotted manure in fairly bounteous proportion, it should be in good condition for planting, an additional forking over of the top 10 inches and mixing well with it some steamed bone-meal—a good handful to each square yard—rendering it even more agreeable to the plants. The actual depth to plant will vary somewhat with the character of the soil. For instance, if it is heavy clay, 3 inches of covering soil will be sufficient; while in that of a very porous nature nearly twice that depth would be necessary, ranging it between these two according to the variation of the soil. At the risk of repetition, it is necessary to emphasise the fact that perfect drainage is essential, and when planting Gladioli in clay soil it is advisable to put an inch of coarse sand under the corms and surround them with the same material; while for the choicer varieties it would be quite worth while to fill in the hole with some good potting soil.

Varieties are now so numerous that it is almost invidious to name any. The majority of those offered by firms of repute can be relied upon to do well, and particulars of these and others large-flowered sorts can be obtained from any good catalogue of bulbs for spring planting. S. X.

SOME NOTES ON LACHENALIAS.

Their Lasting Qualities.—Now that my Lachenalias are almost over, I would like to draw attention to their wonderful lasting properties, both as pot plants and as cut flowers for rooms. Compared with Daffodils, Tulips and Hyacinths, they are like Marathon runners to sprinters. Potfuls last in perfection for quite two weeks, and sometimes longer if they are brought into the house before the top bells of the spike are fully expanded. Of how few other

ANOTHER SEEDLING PINK WITH PLAIN EDGES TO THE FLOWERS.

flowers can it be said that they last in water as well as, if not better than, they do when growing, yet this is literally true of *Lachenalias*. Every year they seem to give me a fresh surprise in the time during which they remain in good condition.

I hope, too, that I am getting a strain which will enable them to be used in average-sized vases, for up till now the great majority of varieties are only possible in low receptacles on account of the shortness of their stems. I have now, however, quite a dozen kinds which in pots look as if the flower-heads were walking on stilts, but which I have found to be the very thing for vases. These measure from 13 inches to 16 inches in length, and have from 9 inches to 11 inches of clear stem before the flower-spike begins (see illustration). They are as different as chalk is from cheese compared with *Cawston Gem*, *Nelsoni*, *Ruby*, *Brightness*, *Shiner*, *Ruth Lane* and *W. E. Gumbleton*. They are more of the type of *Rose Barton*, which is one of the very best of all deep yellows.

I was glad to see that in the list of Frank Lilley of Guernsey last autumn, and also in that of Messrs. Barr and Sons, some of the new varieties were catalogued. It would be interesting to know what sale they had. I fear not a very large one, for the merits of the family are not appreciated as they deserve to be, and yet I know a small band of the faithful do grow them. Mr. George Paul, for example, told me that he had a nice collection. Again, it was pleasant to see the edging of well-grown *Nelsonis* round the Marquis of Ripon's group at the Forced Bulb Show. One of my gardening aspirations is to be able to stage a good group of *Lachenalias* at Vincent Square.

The Routine of Cultivation is, like most other affairs, simple when once its main principles are mastered. When people begin to "pot" grouse, then lose no time in potting *Lachenalias*. They require a rich, light, porous compost with good drainage. Personally, I prefer to put one bulb in a 3-inch pot, and then, when they flower, to turn

the plants out and mass them together in a larger receptacle. At this moment I have two grand bowls made up in this manner. The outstanding features of *Lachenalias* are their singularity in form compared with the usual spring flowers, and their extraordinary staying powers. Their popular English name is *Cape Cowslips*, but a more descriptive one for those who are unacquainted with them would be yellow Wood Hyacinths of the Spanish or campanulata type.

After the Bulbs are Planted they must be placed in cold frames, being careful to protect them from frost and to give as much air as possible, but on no account to subject them to a cold

draught. Bring them into a cool greenhouse about early December, unless there have been hard frosts previously; keep them as cool as possible, and again give air on all suitable days. They will flower about mid-February to mid-March.

After Flowering, and for a short time before, mild stimulants must be given. Soot water and cow-manure water are excellent. The plants must be well looked after till the yellowing leaves show us that the bulbs want to go to sleep and prepare for their summer's baking in the sun. Once the leaves have faded (which time will

of foliage and flower, and makes an attractive object.

I feel I am to some extent a scribe writing in the wilderness in penning my meed of praise for this useful plant. Comparatively few, I find, know it by sight, and fewer still its good qualities for decorating our rooms either in a growing or a cut state. I see it is claimed for the *Gladiolus* in the *Gladiolus Annual* for 1914-15 that it will outlast any other flower in water. I wonder if the writer has ever tested the length of time that a *Lachenalia* will remain good and retain its colour. A *Gladiolus*

may last longer, but when it comes to lasting and retaining its true colouring, I must put in a claim for the *Lachenalia*. J. JACOB.

NARCISSUS NOMENCLATURE.

ON page 113, issue March 6th, the Rev. J. Jacob desires alternative designations for the various classes of *Narcissus*. I wonder why. One name for each class ought surely to be enough, if it has been well chosen. We must suppose, therefore, that Mr. Jacob does not consider those names to have been well chosen which have so long been in use. Neither do I. The attempt to classify garden *Narcissi*, or garden anything, on strictly scientific principles must fail, because the differences which interest the gardener are not the specific differences which alone interest the botanist. In the eye of the botanist there is no essential difference between a *Leeds Daffodil*, a *Barr Daffodil* and an incomparabilis. They are different complexioned children of the same family. To the gardener the complexion is everything; to the botanist it is of no interest whatever. But the *Daffodil* people would have a scientific classification for their flower, and in the *Baker classification* they probably got as scientific an arrangement as the material permitted, though in science a miss is as good as a mile.

One thing at least in the present classification is, after the manner of science, its Latin terminology, and it is for this quasi-scientific jargon, I take it, that Mr. Jacob desires some more intelligible alternative—small blame to him! No doubt what he wants is a serviceable English terminology which we can all use without the risk of scandalising Vincent Square by our pronunciation, reserving the more learned Latin (*Magni-Coronati*, &c.) for *Daffodil* conferences, where a certain show of erudition is perhaps only decent. As a matter of fact, the botanist has, in the *Narcissus*, a hard row to hoe, and I am afraid we, mere gardeners, must leave him to work out his own salvation, wishing him joy of the task. Assuming, then, that an English substitute for the Latin

A VASE OF LACHENALIAS WITH EXTRA LONG STEMS.

probably be early May), keep the soil and pots dust dry, and give them all the sun and air that they can get. Do not turn the bulbs out until a day or two before they are to be replanted. As *Lachenalias* are rapid increasers, the ideal plan is to have two lots of bulbs—one to be used for the indoor decoration of the house, and the other to be grown for stock for another season's planting.

If the one-bulb-one-pot system is inconvenient, six to eight bulbs may be put in a 5-inch pot, or five or six in a 4-inch; or wire baskets may be lined with moss, in which the bulbs may be placed pointing outwards and the interiors filled with soil. A well-grown basket of *Lachenalias* is a mass

terminology is desirable, what are the principles which should determine the selection of names for the recognised classes? In my opinion they are three. The names chosen should be (1) accurate, (2) brief, (3) descriptive. If you can find a name which is all three (not always an easy thing) you have the ideal name. "Trumpet Daffodil" is such an ideal name, whereas "Ajax" is absolutely meaningless. "Poetic Daffodil" is not an ideal name, because it is not correct. In the first place, the "Pheasant's-eye" is not a Daffodil; and in the second, though it may be the Narcissus of the poets, that does not make it poetic. "Poet's Narcissus" is not so much amiss. If, however, you want a name that offends in every way in which a name can offend, you have it in "Angels' Tears Daffodil." It is not brief, and it is not accurately descriptive, or descriptive in any way, accurate or inaccurate. In addition to these negative defects, it is mawkish, ridiculous, uncomfortable to the tongue and harsh to the ear, as anyone can discover for himself by pronouncing aloud "Angels' Tears Daffodil." I have heard of "tears such as angels weep," those, namely, which were shed by a dusky archangel on a certain memorable occasion; but his tears were more likely to have been of molten lead than of the dainty stuff of which triandrus is made. In selecting English names for Narcissi, the plan has largely been followed of naming from a resemblance to some familiar object, sometimes a familiar flower, as in the case of *N. cyclamineus*. Now, I will put to Mr. Jacob this conundrum—"What familiar flower does *N. triandrus* most resemble?"—at the same time beseeching him not to name this exquisite Narcissus *N. euchsiaoides*, for we have had too much dog-Latin already, to say nothing of dog-Greek.

Since Mr. Jacob invites comment on his suggested names for classes, I may say that in my opinion there ought to be no separate class for double flowers. *Telamonius plenus* is as much a trumpet as Emperor, and Codlins and Cream is quite as incomparable as Sir Watkin; nor does a double Jonquil by doubling cease to be a Jonquil. Again, Mr. Jacob's class-names would gain in brevity, and simplicity by the omission of such unnecessary words as "flowered" and "leaved." I submit that "Jonquil" requires no synonym, being already a recognised English name; besides that, the addition of "Rush-leaved" raises the claims of the Hoop-petticoat, which has also Rush leaves, to say nothing of tenuior, gracilis and juncifolius. The points, however, in Mr. Jacob's suggested class designations which seem to me least satisfactory are his Classes 2, 3 and 4. "*Incomparabilis*" is surely a piece of pedantry which it is time to jetison. It is begging the question to call these Daffodils "*incomparable*"; but, if they must have this pre-eminence, there is the word "*Peerless*," which Parkinson, I think, and subsequent writers have applied to these hybrids. Mr. Jacob describes the *Peerless* Daffodils as

"large-cupped"; but is not this description equally applicable to the Leeds Daffodils (to many of them at least)? Would it not be more accurate and consistent to group the *Peerless* and Leeds Daffodils under one division, as is done with the various trumpets, making two sub-divisions—(a) yellow cups, (b) white cups—just as we have yellow trumpets and white trumpets? When one comes to think of it, there are three sub-divisions of *Peerless*, just as there are three of trumpet Daffodils—yellow, bicolor, and white. I question (though the doubt is, of course, a heresy) whether there is any sufficient justification for the existence of a separate Barr group, though on that point I prefer not to commit myself till I have had the opportunity of examining this season's flowers. The Burbidge Narcissi have been eliminated as a separate class and merged in the Barrs. But is there any greater distance between the Barrs and some of the

respectively. Again and again they have come into my mind—few exhibits have given me greater or more lasting pleasure. Before a White Emperor, a Mrs. Ernst Krelage, an Avalon or a Helios one has quite different feelings. They are rather those of cold academic wonder and admiration at what ingenuity and (from a human standpoint) what chance has given us. With such flowers as these cyclamineus hybrids there comes something different. It is the warmth that one's special favourites like *maximus*, *Santa Maria*, *Frank Miles*, *Autocrat*, *White Queen* and *Countess of Southesk* create. This sort of dual personality is a strange phenomenon. Some may experience it, and then they will know my meaning; but to others it will be inexplicable, as, indeed, it is in its origin to myself. Few of these pretty cyclamineus hybrids seem able to stand the vagaries of a mundane existence, and nearly all of them perish after a few years of life. Nevertheless,

CAMPANULA PUSILLA MISS WILLMOTT. THIS LITTLE BELLFLOWER HAS BLOSSOMS OF SILVERY BLUE COLOUR. (See page 188.)

Peerless Daffodils than there is between the Barrs and the Burbidges? SOMERSET.

DAFFODIL AND TULIP NOTES.

BY THE REV. JOSEPH JACOB.

Barr and Sons' Exhibit at Vincent Square on March 29.—In my last notes I referred to the two beautiful cyclamineus hybrids which were staged on this date. I owe readers an explanation of my segment measurements in *THE GARDEN* for March 27. I put the cart before the horse in the case of the cyclamineus hybrid and *Golden Chief*. These should be: S, $1\frac{1}{2} \times \frac{1}{2}$; and S, $1\frac{1}{2} \times 1\frac{1}{2}$

they are worth acquiring, and people should endeavour to have a few pods of seed every now and again, cyclamineus being the seed bearer and some trumpet variety of good constitution the pollen parent.

There were several vases of a new white trumpet called *Gwendolin*, which caught the eye of many. Note-taking for a paper makes one unwittingly play the part of an eavesdropper; visitors blurt out remarks, and one is "forced to hear" them. *Gwendolin* did not, or some part of her perianth would assuredly have gone red. A point of interest was the difference between blooms from the open in Cornwall and pot-grown ones from Taplow. The former were rather young, but I do not imagine they would ever rival the latter, some of which were particularly fine. I measured

one as follows: D, 4; C, $1\frac{1}{2} \times 1\frac{1}{2}$; S, $1\frac{7}{8} \times 2$. In all my measurements, the first figure, when there are two following a letter, is that of the length of the segment (S) or the corona (C), and the second that of the width. My *memoria technica*, or memory aid, is "l" comes before "w." The perianth is ivory white, rectangular and slightly twisted; corona, pale primrose, with a bold, jagged flange or reflex. I must put in a word for Santa Maria, as I am told that it is hardly ever found in a wild state now. Mr. P. R. Barr told me that it is doing very well at Taplow. This is good news. I only wish some grower would find he could grow it as easily as Chickweed; I feel sure it would command a ready sale. The deep tone of its colouring and the exquisite grace of its narrow, much twisted perianth segments differentiate it from all other varieties. I wonder if this is grown and known in New Zealand or Australia. Dimensions of the flower: D, $3\frac{1}{2}$; S, $1\frac{1}{2} \times 7-16$; C, $1\frac{3}{8} \times 1\frac{1}{2}$.

Robert Sydenham, as the number of flowers noted there gives that order a preference. D stands for diameter of the whole flower; S for the inner segments, and the first number will always be the length and the second the width of the inner or minor segments. C stands for corona, and the first number is that of its length and the second that of its width at the top, including the flange or reflex in its natural or unstretched out pose. I advocate measuring the inner segments, for I believe they are invariably narrower than the outer ones. If these are of good width, it seems necessarily to follow that the perianth is imbricated or overlapping.

Technical Terms.—I am so glad Mr. Duncan Pearson has taken the matter up. I made a mistake when I classed Frank Miles as having a twisted perianth. Of course, it does not twist. "Incurving" is the proper word to describe the way the edges of the segments bend inwards. This is a pleasing feature in many blooms; but the

It does not look quite so much as if that monarch had been at a proverbial "bump supper."

Lucifer I must watch more closely. "Hooded" in descriptions seems to be no more favourable to the flower described than is "magenta." By "hooded" I do not mean floppy, and I do not think any seedling will now be allowed to live with the lopped ears of the old Humeis. Can Mr. Pearson suggest a better name for all those perianth which are not rectangular like Tenby? On criticism I have to make on my own suggestions as printed. Before "hooded" there should have been inserted the words "of the perianth" (THE GARDEN, page 125).

James Carter and Co.'s Exhibit on March 29.—The combination of Daffodils and Tulips was a very happy one. Purple and gold go well together. There were three tall stone vases, with their bowls and their bases a mass of King Alfred or Sir Francis Drake. Crocuses of many shades, ranging from deep purple to pure white, surrounded them in circles or formed large diamond-shaped panels between them. The whole display, which occupied a length of half that of the hall, was arranged on the floor and edged with stone kerbing. Mr. Bard is to be heartily congratulated on this fine effort.

TULIPS.

R. H. Bath, Limited, had a very fine display of Darwin Tulips grown in bowls and fibre. It was a pleasing change to see that they were nearly all on the young side, and in consequence freshness was the pervading note. Le Rêve was caught at its very best. Everyone remarked how well it looked. With this exception and one vase of Suzon (Rectified), all the other Tulips were Darwins. I append their names: Mrs. Potter Palmer, Melicette, Circe, Euterpe, Suzon, Maiden's Blush, Bartigon, Isis, Wedding Veil, Paris Valentine, White Queen, Sierrad van Flora, Rev. H. Ewbank, Palisa, W. Copland, Erguste and Pride of Haarlem. Circe is not so well known as the others. In pots and bowls it looks like a paler Rev. H. Ewbank.

A CHARMING LITTLE BELLFLOWER.

OF all the dwarf Campanulas or Bellflowers that are hardy in this country, it would be difficult to find one that is more charming than C. pusilla Miss Willmott. This glorious little plant has flowers of pale silvery blue, not unlike those of the common Harebell of our roadsides and downs. As will be seen in the illustration on page 187, it is perfectly at home in the rock garden, where it quickly makes large tufts of neat green foliage, surmounted, during July, by a cloud-like mass of dainty pendulous blossoms. It is also one of the best Bellflowers for planting between paving-stones, where the colour of the flowers harmonises perfectly with weathered York stone, or contrasts pleasingly with the dull red bricks that do duty for pathways in many places.

SAXIFRAGA LINGULATA.

THIS beautiful long-leaved Saxifrage is, to my mind, one of the most decorative of the silvery or encrusted family. It makes peculiarly "spidery" rosettes of narrow, heavily lime encrusted leaves, and when the crowns are mature they throw up during May an inflorescence of great beauty, as will be seen from the illustration above. It will be noticed what an immense number of flowers are produced on such a spike.

A BEAUTIFUL ENCRUSTED ROCKFOIL, SAXIFRAGA LINGULATA.

Maid of Athens, a nice, small-cupped Leedsii with pointed segments, showed up very well. I also noticed Mohican—Canon Fowler drew my attention to it. I do not think I had ever realised what a bright cup it has; in this respect it puts its triplet brother, Sunrise, in the shade—I had written "twin brother," but Mohican is one of three, Sunrise and Sunbeam being the other two that came from the same pod. Mohican is a good substitute for Sunrise, particularly as it is so much cheaper. There were two or three fine vases of the large red-cupped Daffodil Sparkler. It has all the look of what it is—an M. J. Berkeley seedling. Admiral Togo, with its clawed or campanulate perianth, was in good condition. I liked its beautiful Nelson shade of yellow.

Measurements.—I intended to send a short notice of my future intentions with regard to the order in which I am taking measurements down, but have not done so. I purpose in future following that of "All About Daffodils," by the late

reverse, the curling back of the petals, is atrocious. I find, too, I wrote "Queen" for "King," and *vice versa* in describing the tops of the coronas of King and Queen of Spain.

With respect to "flange," it does not seem a bad word, as it conveys the idea that the corona is not a top hat with the brim cut off. Mr. Pearson's word "reflexing" is adjectival, and needs a defining substantive, for the only approaches to a true reflexing corona that I have seen are those of the "thumbis." A railway line is not a bad thing, after all, and between the flanges on the rails and those on the carriage wheels we manage to get to London. Corona, too, means crown, and crown suggests metal, and metal suggests flange, and flange suggests, when coupled with a Daffodil, that animation which gives a face so often its charm and a Daffodil hardly ever. I think I would rather talk of King Alfred's flanged crown than his gashed brim (Messrs. J. R. Pearson and Co.'s catalogue of bulbs, 1913, page 44).

while, given reasonable weather conditions, the display lasts for three or four weeks. Provided the soil is thoroughly well drained, this plant does not seem unduly particular as to compost. I grow it in gritty, sandy loam, leaf-mould and old mortar, where it thrives apace, and also in the moraine, where, by the way, the accompanying photograph was taken. The rosettes are best inserted just above a steeply inclined part of the rockery, so that the more or less horizontal spray may have ample room to show off its full character. It will be noticed in the illustration how decorative the foliage is, especially when the rosettes are colonised in a slanting fashion, as there shown. This plant is sometimes spoken of by its synonym *Bellardii*, though from the examples which I have seen in my friends' gardens, the true plant is not well known.

It hails, I believe, from the Italian part of the Maritime Alps, in the neighbourhood of the Col di Tenda, where it is plentiful. The variety *lantoskana* is readily distinguished from the plant under review, on account of its rather more arching inflorescence, which has the bulk of the flowers crowded on the upper surface—giving it a beautiful fox-brush-like appearance—while the leaves are more blunt, decidedly reflexed and prostrate, the rosettes being only about half the size of *S. lingulata vera*.

R. A. MALBY.

SOWING WALLFLOWER SEED.

THESE are few old-fashioned flowers more highly appreciated than the Wallflower. For its scent alone it is always sure of a welcome, but if the varieties are well chosen, their colour also plays a by no means unimportant part in the decoration of the spring garden. The best time for sowing seed has long been a debatable point among gardeners, some preferring to do the work at the end of April, and others delaying it until at least a month later. If the resultant plants receive really good treatment and are not planted in over-rich soil, and are given plenty of room to develop into robust, short-jointed specimens, there is a good deal to be said in favour of the earlier date. On the other hand, if grown too quickly they are likely to get too large and soft to withstand a severe winter, and under such circumstances one would favour a month hence. Their treatment for ordinary purposes is so well understood that it is not necessary to do more than remind readers of the time for sowing. But where they are grown in the crevices of old walls or natural rockwork, positions for which they are admirably adapted, they need rather different treatment. Here it is undoubtedly much the best plan to sow the seeds where the plants are intended to grow and flower. Wallflowers, under the best circumstances, need some care and preparation for transplanting, and if they must be moved to positions such as those now under notice, they must be transferred while quite small. It does not, however, matter much whether April or May be selected for the sowing; but showery weather, so that the small quantity of soil may be made as retentive as possible, should be chosen. In common with some other flowers, the Wallflower has been almost spoiled by so-called improvements. Those with blooms of dirty creamy yellow hue or a nasty magenta purple are mere caricatures of a dear old fragrant flower.

A. B. ESSEX.

DARWIN AND COTTAGE TULIPS IN THE FLOWER GARDEN.

WHEN spring has gone and the exotic and other summer flowers are still under the sheltering care of the greenhouse or frame, the beautiful colours of the Darwin and Cottage Tulips add to the gaiety of the garden. All who cherish the flowers of the spring months have more than a passing acquaintance with the early Tulips, or "Dutch" as they are more familiarly called, the *Duc van Thol*, *Couleur Cardinal*, *Prince of Austria*, *Maas*, *Rose Luisante*, *Vermilion Brilliant* and many others; but the groups indicated in the heading to these notes should win a larger degree of popularity. I was last year looking at a glorious display—a perfect picture of colour association—white, mauve, crimson, lilac and pink, with many exquisite shades, and painted on thick petals composing flowers of goblet-shaped form, held on strong, tall stems. Probably one of the reasons of the comparative neglect, if we may so call it, of these Tulips is that many hardy flower lovers are unaware of their vigorous beauty. I have grown a large variety for many years, and have urged their more general use, not only for their gorgeous beauty in the open garden, but for cutting to fill vases in the house, in which they will remain for days in full beauty, the flowers even developing under these conditions. It is always wise to seek out some good garden or nursery in which the Tulips are grown and choose the colours that appeal most strongly to the individual taste, thinking out also beautiful contrasts, the length of stem enabling many dwarf plants to cover the ground beneath the flood of flowers. It may be asked whence came the "Darwin" Tulips. The name was given in honour of Darwin and to set seal to a distinct and noble group of Tulips that have their origin in *Tulipa gesneriana*, which is as much sought for as its offspring. A bed of this glorious flower is in the full flush of its scarlet beauty early in May; and it is in a group that this colouring is most assertive. A little forest of stems hold huge goblet-like flowers that glow in the sunshine and open out at midday to disclose a deep purple pool of colour in the base. Before all other May Tulips I would select this, queen of the whole family and one of the most reasonable in price. A groundwork of white *Arabis* or white *Tufted Pansy* throws into rich relief the scarlet colour, and, passing to the warm purple shades, a planting of yellow *Polyanthuses* affords a strong and agreeable contrast.

Catalogues and books give long lists of named kinds, and I will mention a few that seem the most picturesque in all ways, possessing remarkable strength of growth and fine colouring. These notes will, it is hoped, prove acceptable to those who are unable to see a collection in bloom but wish to plant the bulbs in autumn. The Darwin group contains the following forms that were chosen for their beauty and splendour in the garden in May and early June: *Carminea*, intense rose carmine, height of stem, 22 inches; *Clara Butt*, one of the most beautiful of the May Tulips and the most popular in Covent Garden Market, the colour a peculiarly beautiful soft rose and the petals of faultless form, 19 inches; *Glow*, vermillion, with deep blue-purple centre; *La Tulipe Noire*, an intensely dark colour, deeper even than

Vulcan, 24 inches; *Dom Pedro*, mahogany colour, 24 inches; *Loveliness*, satin rose; *Pride of Haarlem*, rich salmon, shaded with cherry colour, 26 inches; *Rev. H. Ewbank*, silvery heliotrope, with a margin of a shade that has been well described as dove grey; *Erguste*, deep silvery heliotrope; *Suzanne*, a delightful colour, a mingling of rose and apricot, tall, graceful and one of the kinds that should certainly be chosen; *La Réve*, satiny rose pink; *Tak van Poortvliet*, warm rose salmon, with a soft base, a strong and fascinating contrast, 25 inches; *The Sultan*, or the *Black Tulip* as it is frequently called, a deep maroon approaching black, with wide, strong segments and tall stem, no less than 28 inches. This and *Clara Butt* are planted perhaps more largely in the flower garden than any of their race, and the duskiness of the former contrasts intensely with white flowers such as *Arabis albidia*. *Remembrance*, rich silvery mauve, 24 inches; *Corydon*, a shade of heliotrope, 20 inches; *Black Knight*, deep maroon; and *Zanzibar*, dark maroon, exquisite in the sunlight, complete the list of those that were carefully chosen for a large collection. But few of the Darwin Tulips are unworthy of our consideration, either for growing by themselves or in association with dwarf alpine.

In the great throng of May Tulips, those called "Cottage" deserve as warm a tribute for their rich and varied beauty as the Darwin section that I have just considered. An atmosphere of the Old English garden permeates this beautiful race, and many of those we cherish in our borders have been gathered from the cottage plots in the British Isles and some from the old parterres of France. Fifty and more years ago these Tulips opened their glorious chalices to the spring sun, and it is strange that many of them degenerate when brought, if one may so express it, "under cultivation." Generations passed by, but still in the homely cottage garden the Tulips never failed, year by year bearing company with the flowers of spring.

A garden should contain the following: *Amber Crown*, amber, as the name suggests, tinted with apricot; *Blushing Bride*, cream suffused with pink, which changes to bright rose carmine, 15 inches; *Bouton d'Or*, intense golden yellow, 17 inches; *Dainty Maid*, white, marked with lilac; *flava*, soft lemon colour, 28 inches; *fulgens*, brilliant crimson, 24 inches; the form of Gesner's Tulip called *spathulata*, *Golden Crown* or *Eagle*, yellow, flushed with orange red, the anthers black, 18 inches; *Golden Glow*, rich yellow, 16 inches; *Inglescombe Pink*, *Inglescombe Yellow* and *Inglescombe Scarlet*, a trio of splendid Tulips, 20 inches; *ixioides*, yellow, with a rich black base, 22 inches; *La Merveille*, rose salmon and orange red, very fragrant, 18 inches; *Leghorn Bonnet*, chrome yellow, beautiful in shape, 20 inches; the sweet-scented *crimson macrospeila*, 18 inches; *mauriana*, glowing scarlet, golden centre, 21 inches; *Mrs. Moon*, pointed petals of deepest yellow, one of the finest of all May Tulips, 28 inches; *Orange King*, a lovely orange tinged with scarlet, very sweet, 22 inches; *Parisian Yellow*, 20 inches; *Picotee* or *Maiden's Blush*, white, edged with rose, 20 inches; *retroflexa*, yellow-pointed segments, 16 inches; and *The Fawn*, a soft shade, indicated by the name. A few of these are, correctly, species, but all are noble garden flowers for the month of May; colour, scent, length of flower-stem and broad grey foliage are the attributes of this race.

W. F.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Late Vines.—Remove the surplus shoots as soon as it can be seen which are the best to leave to supply the crop. Although it is essential that the trellis is well covered with foliage, plenty of room must be allowed for the leaves to develop without crowding, or there will be danger of the Grapes not finishing perfectly. If the Vines are infested with mealy bug, an effort must be made to destroy it before it reaches the young growths, as it is very hard to get rid of if neglected during the early stages.

Melons.—The fruits on the earliest plants will now be swelling freely, and in order to get Melons of the best flavour, the plants must be liberally fed with stimulants. During the final stages of growth liquid cow-manure given at full strength will be found an excellent stimulant. When the fruits commence to colour, water must be gradually withheld and the atmosphere kept drier, admitting plenty of air to the house on all favourable occasions.

Melons in Frames.—Preparations may now be made for growing a batch of Melons in frames. It is an advantage to have a mild hot-bed on which to grow the plants, and during the growing season the best use must be made of sun-heat by judicious ventilation of the frames, closing them early in the afternoon after spraying the plants with lukewarm rain-water. The variety *Eminence* will be found very suitable for frame culture.

Plants Under Glass.

Coleus thyrsoides.—This is an excellent plant for conservatory and greenhouse decoration during the winter months. If cuttings are available, they may be inserted now and placed in the propagating-case. During the growing season a house of moderate warmth will be suitable, and unless very tall plants are required, they may be stopped once or twice during the season to keep them dwarf. A batch of cuttings can be inserted later, to flower in small pots.

Gloxinias.—Plants coming into flower must be well supplied with stimulants. At this stage cooler conditions will prolong the flowering season considerably. Pot on seedling plants before they become potbound, and keep them moving in a warm, moist house. These will flower in 5-inch pots.

Eranthemum pulchellum.—This is a useful winter-flowering plant of easy cultivation. Cuttings will readily root in a sandy compost. Insert three or four cuttings round the sides of 3½-inch pots and place them in the propagating-case. When rooted, pot them singly into 3½-inch pots and grow them on in a warm house. The growth will require stopping twice during the early part of the growing season to induce a bushy habit.

Nerines.—When the foliage shows signs of ripening, water must be gradually withheld, thus inducing the plants to rest.

The Flower Garden.

Seedlings.—Many seedling plants may now be put in their flowering quarters if these are vacant. Such plants as *Antirrhinum*, *Dianthus*, *East Lothian Stocks*, *Larkspurs*, *Matricarias* and *Scabious* may be put out; but in the event of cold east winds, a few boughs of evergreen should be placed among them. *Mignonette* ought to be sown in suitable places at regular intervals. *Nasturtiums* may be sown either in their flowering quarters or in boxes. The *Tom Thumb* type is excellent for massing, but the plants must not be put in rich soil, or flowers will be scarce.

The Rock Garden.—Many subjects may now be planted out on the rocks. For summer effect *Campanulas* can be largely employed. Most of the species are easily propagated from cuttings inserted whenever they are procurable. *Geum Mrs. Bradshaw* is excellent for massing in bold schemes of rockwork, and is easily raised from seed sown as soon as it is ripe. Many annuals may be sown on the rocks, and some should also be sown in boxes to take the place of plants which will be out of flower during the summer months.

The Hardy Fruit Garden.

Strawberries.—Some of the later batches of plants which have been forced may be saved for planting outdoors. With proper care these should give an excellent crop of fruit next season. If the ground is ready, they ought to be planted as soon as they have been hardened off a little. Keep them well supplied with water till they have become established. The young plants which were put out last year for the purpose of supplying runners should have their flower-spikes removed. To encourage strong growth, give them light dustings of soot and hoe them frequently.

Raspberries.—The young growths which are now pushing from the base of the plants must be thinned out, leaving only sufficient to replace the old fruiting wood. If not already done, the roots should be mulched with rich manure. Autumn-fruiting varieties must also be thinned severely, or the crop will suffer.

The Kitchen Garden.

Celery.—Endeavour to grow the plants as sturdily as possible by admitting plenty of air to the frames, removing the lights entirely during favourable weather. Water liberally at all times. Prick out later plants before they become drawn. If the soil is placed on a moderately warm hot-bed, it will greatly facilitate the growth of the plants.

Seed-Sowing.—The seeds of Broccoli, Savoys and all winter greens may be sown within the next fortnight. Sow in drills 12 inches apart in soil which is not too rich.

Asparagus.—Seeds may now be sown in the open in drills 18 inches apart, or in small pots. Where time will allow, the latter method is best, as the plants may be put out without a check.

French Beans.—A batch may be sown in small pots for planting out in a sheltered situation. They may be placed in a moderately warm house to germinate, and be hardened off in a cold house. If a frame is available, another batch may be sown therein. The variety *Belfast* will be found suitable for this purpose.

E. HARRISS.
(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Potatoes.—The planting of maincrop varieties ought now to be proceeded with. The importance of an occasional change of stock of this vegetable cannot be too strongly advocated.

Runner Beans.—If a portion of this crop is needed two or three weeks earlier than the main crop to be sown outdoors, some seeds may be sown in 5-inch pots and grown on in cold frames until all danger of frost is past, when the seedlings can with safety be planted.

Onions which were sown indoors during January, and which have been hardening off recently in cold frames, should now be planted out. Slightly more room ought to be allowed them than the general crop sown some time ago. See that the soil is in a firm condition and be careful not to plant too deeply, leaving the small bulbs just on the surface of the soil.

Turnips.—It will now be safe to make a fairly large sowing of this vegetable for use in June and July.

Carrots.—The main crop may now be sown whenever the conditions are suitable. This crop is a worry to many vegetable-growers, but by frequently dusting with soot and other antidotes it is possible to keep the dreaded Carrot fly well in check, if not to get rid of it altogether.

Seakale.—If the supply of this vegetable is required up to a late date, crowns can be placed behind a north wall, where they can be blanched by being covered with fine ashes.

Fruit Under Glass.

Early Vinery.—As the Grapes in the early house are now stoning, no sudden fluctuations of temperature must take place, as this is a very critical time. It is at this period when scalding

is likely to happen if the treatment is not correct. If the border in which the Vines are growing is constructed to allow for proper drainage and the depth is correct, stimulants may be watered in more frequently than would be safe in a deep border with faulty drainage.

Muscat of Alexandria.—This Vine succeeds best in a rather higher temperature than most Grapes. Especially is this important when in flower; then a temperature of 80° to 85° should be the rule by day, with 65° as a minimum by night. A drier atmosphere must be maintained until the setting period is over. As this Grape is not so even a setter as some, a few spare bunches should be allowed to remain until it is certain a successful and even set has been assured.

Late Vines.—As these are now making quick progress, disbudding must receive attention. The rods should now be secured in their places. If the spurs are rather long, it will be an advantage when tying if they are slung a few inches below the wires instead of securing them actually to the wires.

Melons.—After the fruit has set and commenced to swell, more liberal treatment must be given the plants. As surface roots appear, a top-dressing of fine soil to which some fertiliser, such as *Clay's*, has been added, will be of great service. Secure all the sun-heat possible by closing the house as early as it can be done with safety from scorching. The syringe must be used freely if spider is to be kept in check.

Plants Under Glass.

Cyclamen.—Seedlings which were raised in the autumn and potted into 2-inch pots during the winter ought now to be moved into 3½-inch pots. See that the compost is made porous by including plenty of coarse silver sand. The leaf-soil used should be obtained by rubbing clean leaves through a half-inch mesh sieve. Fumigation is necessary at intervals to keep down thrip, to which *Cyclamen* are very subject.

Reinwardtia trigyna.—Where one has to keep up a display of flowers in a show-house, this subject will be found invaluable from Christmas onwards. Used in connection with *Cero-dendron fallax* it is very effective. After taking cuttings, which root very readily, it should be grown in the cool end of a stove. It is also possible to have it in the form of a standard up to the height of 2 feet 6 inches. Although a useful subject in the show-house, it is not adapted for house decoration, as it has a tendency to drop its flowers if handled very much.

The Flower Garden.

Evergreens.—All planting should cease soon after this date. If the ground is very dry, a watering should be given; and if dry winds or bright sunshine continues, temporary shading, in addition to an occasional syringing, will greatly help the transplanted trees or bushes to recover.

Boxwood.—As danger from severe frost is now past, it will be safe to commence the annual clipping of all Boxwood edgings. Formal bushes and topiary subjects should also be attended to.

Half-Hardy and Hardy Annuals.—Whether used to help the display in the herbaceous border or to be grown in a position by themselves, the majority should now be sown, except when a succession of any special subject is required; then another later sowing will be necessary.

Herbaceous Borders.—If the weather is at all dry, this border should be gone over with the hoe. If time permits, many of the *Phloxes*, *Asters* and kindred plants will make much finer heads if the young growths are reduced at this season.

Dwarf Bedding Lobelias.—Whether propagated from seed or cuttings, the plants ought by this time to be sufficiently advanced for removal to cold frames. After pricking out in good sandy soil, the frames should be kept closed and shaded for a few days.

Marigolds.—All varieties of these annuals must now be sown, including the useful *Legion of Honour*. Either a slightly heated frame or a mild hot-bed will suit the requirements of these plants best.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

DWARF PLANTS FOR FLOWER-BEDS.

EARLY spring is the time to make notes for future planting, and at this season those who care for their gardens should be thinking out future work. One point which frequently produces a discordant note during winter and spring is the large expanse of bare soil in shrubberies and thinly planted beds of shrubs. This, however, may be obviated to a large extent by carpeting the ground with plants which are not of rank growth. In selecting subjects it is always advisable to choose those which bloom and mature their growth early, for then the dead leaves may be cleared away before many weeds appear and before the majority of shrubs are in flower. Daffodils are bad plants for the shrubbery, for the foliage is coarse and does not die down until midsummer. Small-growing plants do not rob the ground so seriously, while, if they are kept at a little distance from the shrubs, they do not interfere much with them. Rings which are kept free from grass round the bases of trees may also have a carpet of bulbous plants, for they do not keep away moisture from the roots of the trees as in the case of a thick mat of turf. In addition to being beautiful in themselves, some of these carpeting plants are valuable on account of the contrast they give to early flowering shrubs in the same bed, and, in planting, consideration should be given to possibilities in this direction.

The earliest effects are those produced by Snowdrops and Winter Aconites, which may be used separately or in combination, the display in either case being effective. As a groundwork for Witch Hazels, Snowdrops are delightful, the glistening white of the carpet forming a beautiful contrast to the gold of the Hamamelis. Following closely on these plants are the Crocuses in mauve, white, yellow and purple, one and all combining to make an imposing display. White Crocuses used as a carpet beneath Cornus Mas are well worth trying; while yellow or mauve varieties surrounding a tree of Prunus davidiana alba are effective. Crocuses are perhaps the best of the dwarf bulbous plants to naturalise in grass, for they continue to thrive and increase in grass that is mown regularly with heavy machines from the time the leaves die down until late autumn, an operation which a great many plants would not long survive.

Blue flowers are introduced by the various Chionodoxas and Scillas, and what glorious displays they make, the different shades of colour being particularly pleasing. For carpeting beds of Forsythias or Magnolia stellata they are specially attractive, the latter shrub being peculiarly appropriate for a groundwork of blue, the white blossoms forming an admirable contrast. Good kinds to plant are Chionodoxa Luciliae and its varieties sardensis and gigantea, and Scillas bifolia and sibirica. Brodiaea uniflora is well adapted for making a carpet of flowers, and is suitable for a position about the base of a young tree. A charming blue-flowered bulbous plant is Muscari botryoides, while the form called Heavenly Blue is specially worthy of note. This increases amazingly, and may be lifted and divided every three or four years.

Turning from the strictly bulbous plants, we find others with corms or underground stems which are well worth using. The hardy Cyclamens form charming groups, and are effective by reason

of their richly marbled foliage and rosy purple flowers. With a selection of several kinds, flowers may be had from autumn until late spring. Such kinds as cilicicum, Coum, europæum, ibericum, libanoticum and neapolitanum are all attractive. These well repay a little trouble, the colour of the flowers being different from that of most dwarf-growing plants suitable for the same purpose. In addition to being of service for carpeting beds, C Coum may be planted in grass where it is short and the ground of a more or less spongy character.

Anemones naturally demand attention for the purpose under notice, and nothing can be more beautiful than the graceful inflorescences of some of the kinds. The common Windflower (Anemone nemorosa) is delightful, whether seen growing wild, carpeting a wood or plantation, or planted as an undergrowth to a bed in the garden. In addition to the type there are several varieties which are of value, such as flore pleno and robinsoniana, the former being remarkable for its double flowers and the latter for its finely formed and large blooms. The common Hepatica (A. Hepatica) is well known, and is charming in early spring when carrying large quantities of flowers. A considerable variation in colour is noticeable, for there are forms with blue, white and red flowers. A species of Anemone with pretty blue flowers is A. apennina; it is quite dwarf and makes an admirable "carpet." A. ranunculoides is a yellow-flowered Windflower, which is a decided change from other sorts; it is worth planting beneath a white-flowered tree. A. Pulsatilla (the Pasque-flower) is charming when growing vigorously in a shady place. It is by thinking out such effects as these that our gardens are made both beautiful and interesting. W. D.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

TREES AND SHRUBS.

SALISBURIA WITH PENDENT BRANCHES (H. H.).—The specimens of Salisburia adiantifolia you mention as having pendent branches were probably the female form of the tree, which is usually acknowledged to be of more pendent habit than the male form. Although many examples of this tree are sparingly clothed with branches and rather gaunt in a young state, they become well branched in later life, and form very handsome specimens. We know of male examples in this country which are very beautiful trees, of easy and graceful outline.

ROCK GARDEN.

VARIOUS ALPINE PLANTS (A. H. Lyne).—You appear to be peculiarly unfortunate in growing some of these, and in certain instances we can only conclude they are affected by local conditions of which we have no information. The Ramondia, which you are unable to flower, is a case in point. Grown in sandy loam or this and peat equally, and given a westerly exposure and half vertical position with moisture assured, the plant is usually very free-flowering. In a similar soil mixture, with moisture assured at the root, it is perfectly

happy in full sun. The Nierembergia loves a half-boggy spot in sandy peat or loam, carpeting the earth and flowering freely. The slug pest of this and Aster alpinus should be kept in check by the usual means. Lay flat slabs of rock, bricks or boards near the plants and strew bran beneath. In this way the slugs are attracted and easily destroyed. The Gentians are as great a puzzle culturally as they are fascinating florally, and their charms should tempt cultivators to wrestle with their caprices till they are overcome. Generally they love cool soil and moisture, detesting drought and parched conditions. You are fortunate in growing G. verna so well. You should be the better judge on the spot as to whether the loss of the flower-buds of the alpine Phloxes is due to birds or slugs. The former may be deterred by a few strands of thread placed early over the plants, which may be removed at flowering-time. If the flower-buds are devoured by slugs, the pest will almost surely leave its trail, and will be found usually secreted beneath the tufts. Lay traps as above.

THE GREENHOUSE.

CYPRIPEDIUM FOLIAGE BROWN (A. C. G.).—The source of the trouble with the Cypripedium foliage is to be found in the watering. Possibly your plants have been overwatered, sprayed during a falling temperature, or watered with liquid manure.

CLEMATIS INDIVISA NOT THRIVING (J. E. L.).—Yes; ants are quite likely to carry the scale from one plant to another, and probably you have some other plants in the house infested with it. Search would reveal the position of the ants' nests, and they should be destroyed by burying a piece of potassium cyanide in them (if no animals or children are likely to be about), pouring boiling water into them in the evening, or water in which carbolic acid is dissolved. These measures, with attention to other plants which are attacked near by, and persistent spraying with paraffin emulsion (paraffin, 2½ pints; soft soap, quarter of a pound; water, 10 gallons) should keep the pest in check and allow you to grow the plant satisfactorily.

ADVICE ON SOIL FOR ORCHIDS AND ON STOPPING CARNATIONS (A. H.).—Cattleyas may well be potted in nothing else but sphagnum moss and peat, though some cultivators prefer a sprinkling of silver sand. The proportions should be two-thirds good fibrous peat to one-third sphagnum moss. Owing to suitable peat being scarce, Osmunda fibre is now greatly used in its stead. Generally speaking, the best compost for Cypripediums is one-half yellow loam and one-half fibrous peat, with a good sprinkling of sphagnum moss, silver sand, and small crocks broken up to about the size of Peas. Peat and moss alone has scarcely body enough in it for Cypripediums in general. The outdoor Carnation: raised from layers and planted last autumn must not be stopped, otherwise you will remove all the best flowers.

TREATMENT OF AZALEAS AFTER FLOWERING (J. T. H.).—Whether pot-grown Azaleas should be pruned or not after flowering will depend upon their condition. If they are good, shapely plants, cutting of any kind will not be needed; but if there are straggling shoots, these should be cut back. Sometimes it will be necessary to prune a plant rather severely, in which case re-potting, if it is needed, should not be done till the young shoots make their appearance. The plants will break out into growth all the more readily if kept somewhat warmer than before and frequently bedewed with the syringe. Those that have not been pruned may be re-potted directly the flowers are over, that is, if they require it. Azaleas, however, do not need annual re-potting, in which case an occasional dose of weak liquid manure and soot-water combined will be beneficial during the growing season.

PROPAGATION OF AZALEAS (S. T.).—You do not say whether your question refers to the Indian Azaleas, which in a great number of varieties are so much used for the decoration of the greenhouse during the early months of the year, or to the hardy kinds, which yield such a wealth of blossoms out of doors in the spring. The Indian Azaleas, which are tender, are evergreen in character, while the hardy kinds are deciduous. Propagation of the Indian varieties is almost universally carried out in Belgium, very few being increased in this country. The war did not seem to lessen the supply much last autumn, but it is more than probable that there will be a great shortage this year. A few of the Indian varieties are struck from cuttings, but nearly the whole of them are increased by grafting. The stocks employed are a couple of strong-growing kinds, concinna and phœnicea, propagated from cuttings. These cuttings are taken in the autumn or winter, dibbled into pans or boxes of sandy soil, and kept close in a warm propagating-house. When rooted they are potted into small pots, and grafted in the August following. If your question refers to the hardy kinds—and we should rather be inclined to think it does—it may be noted that large quantities are raised from seeds; but for the increase of named varieties, grafting is the method generally employed. For stocks on which to graft the best forms, seedlings of the same class are chosen. They are established in small pots, and grafting is usually done in the autumn. After this operation they must be kept quite close in a shaded propagating-case till a union is complete, which will take a couple of months or so. Though grafting is carried out in a wholesale manner in some trade establishments, a good deal of practical knowledge and different appliances are necessary, so that it can scarcely be recommended to the amateur. Seeds readily ripen, and young plants can be freely raised in this way. The seeds are very small and should be sown as soon as ripe in clean, well-drained pans, using for the purpose a compost made up of one

part of loam to two of peat, and about half a part of sand. Care must be taken not to cover the seeds too deeply, a sprinkling of silver sand being quite sufficient. Placed in a snug little structure where a temperature of 50° to 60° is maintained, the seeds will soon germinate, and when the young plants are large enough, they must be pricked off singly. If no warm house is available, they should be placed in a frame and protected from frost. Plants raised from seeds cannot be depended upon to perpetuate any particular variety. The best work on the subject is "Rhododendrons and Azaleas," by William Watson, Curator of the Royal Botanic Gardens, Kew, published by T. C. and E. C. Jack, 16, Henrietta Street, W.C.; price 1s. 6d. net.

KITCHEN GARDEN.

THE CULTIVATION OF HARICOT AND BUTTER BEANS (*Nemo*).—The Haricot Bean is the ripened seed of *Phaseolus vulgaris* and other species of *Phaseolus*, as also is the Butter Bean. The culture is very simple—the same as in the case of the ordinary French Bean. Sow in a deeply dug and generously manured border in a sheltered and sunny position the second week in May. The rows should be 2 feet apart. Draw a fairly wide drill 5 inches deep and plant two rows of seeds in each drill thus: * * * * * the seeds to be 4 inches apart. Earth up with soil when the plants are 6 inches high, not burying the stems too deeply. Give the rows a good watering just before the Beans come into flower, and then top-dress the soil with rotten farmyard manure 3 inches deep. As soon as a crop of pods is formed, give another good watering. Keep the ground clear of weeds. The crop will ripen in due course, and when properly harvested the Beans, if kept in a fairly dry, cool place, will keep well for at least a year. Messrs. Sutton and Sons of Reading advertise seeds of these Beans for sale.

MISCELLANEOUS.

HAUNTS OF THE EARWIG (*T. G.*).—Early in the year the female earwig, which has sheltered through the late autumn and winter in holes of various kinds—in fact, in any convenient place—lays eggs in a hole in the ground, under stones, among dry leaves, fifteen or twenty being laid at a time, and remains with them, collecting them together again if they become scattered. After a month they hatch out and the young earwigs remain for a time with their mother. The clearing away of rubbish of various kinds is, therefore, an important step in preventing the attack of earwigs in the succeeding season. In addition to this, disturbing the hiding-places in the spring and seeing that all walls are properly "pointed" would be wise measures. Trapping by means of inverted pots pressed full of hay would reduce the numbers considerably, and if they are shaken out into a pail of boiling water, or water on which a thin layer of paraffin is floating, they are easily killed.

THE EDITOR'S TABLE.

Green Peas for Winter and Spring Use.—Messrs. Barr and Sons of King Street, Covent Garden, send us a packet of their specially selected dried Marrowfat Peas, which, after testing, we have no hesitation in describing as infinitely superior to the dried green Peas sold by grocers. A pint packet, sold at sixpence, post free ninepence, is ample for six persons, and the flavour and quality are excellent. They are easily cooked, and at a time such as the present, when so much attention is being given to wholesome food, we have no hesitation in recommending these Peas.

Carnation Nora West.—The floral committee of the Perpetual-flowering Carnation Society met on March 29 to consider the variety Nora West for a first-class certificate. This salmon pink variety gained an award of merit on December 2, 1914, which rendered it eligible to enter for the higher award. The floral committee, under the chairmanship of Mr. W. H. Page, after closely inspecting the variety as it was growing at the nurseries of the raiser, Mr. George West, Datchet, Bucks, awarded it 85 points. Nora West thereby receives a first-class certificate, an extremely rare award.

Mauchline Flower Show.—The executive have decided to abandon for this year, on account of the war, the annual show of the Mauchline Horticultural Society.

OBITUARY.

GEORGE GREIG MONCUR.

THE death is announced of Mr. George Greig Moncur, of the well-known firm of Messrs. Mackenzie and Moncur, Limited, horticultural builders and hot-water engineers. Mr. Moncur was well known and respected among horticulturists and others with whom his firm did business. He died at Preston Lodge, Prestonpans, on March 31, at the age of seventy-six. He was interred in the Dean Cemetery, Edinburgh, on April 3.

GEORGE NETTLESHIP.

WE regret to have to record the death of Mr. George Nettleship, one of the best-known amateur horticulturists in the South of Scotland for many years, and one who did much to advance all horticultural movements in the district in which he resided. Mr. Nettleship was a teacher, and was for forty-five years the head-master of Sibbaldie School, Lockerbie, only retiring about eight years ago. As a horticulturist Mr. Nettleship was much esteemed, as he was not only an able cultivator, but a judge whose services were in constant request at the most important shows over a wide area. He was a specially good grower of produce for exhibition, and flowers and vegetables from his garden made a good appearance at many of the shows. Florists' flowers were among his favourites, such subjects as Pentstemons, Phloxes, &c., being admirably grown by Mr. Nettleship. In his private life he was much esteemed, while he took part in a number of local movements of a laudable nature. He was predeceased by Mrs. Nettleship. Our sympathy is extended to his family.

SOCIETIES.

AN AMERICAN FLOWER SHOW.

THE INFLUENCE OF BRITISH GARDENERS.

FOR the third year in succession the gardeners and florists within get-at-able distance of New York City have concentrated their efforts, with very great success, upon a great flower show. This exhibition has been held in the largest and most conveniently situated hall, the Grand Central Palace. It is a big square building of many storeys, and the two lower floors are well lighted and excellently adapted for the purpose of a horticultural exposition. The massive pillars and the balustraded balcony are very daintily and elegantly draped and festooned with Southern Smilax, which grows wild in the South, and this form of decoration adds immensely to the scenic effect. Soft electric lights illuminate from the roof every inch of interior space.

This year's show, held from March 17 to March 23 inclusive, a period of exactly a week, was notable because of three features in particular, namely, a small rock garden display by the Julius Roehrs Company, two Rose gardens each covering 500 square feet of space, and a class for a decorative group of flowering plants. In this latter there were six entries, all by private gardeners—men from the Old Country. In the Eastern States there are hundreds of Scottish and English gardeners, and these are the men who are so largely influencing American horticulture to-day. Their American brethren of the craft welcome them. "The English have gardening in their blood," was the remark made by one of them—English, in this sense, comprising all those from the British Islands.

The six groups of flowering stock were on the lines, generally, of what one sees at Shrewsbury Show, except that foliage plants were excluded. Much taste and skill was shown in the arrangement of at least four of them, and it was remarked on all hands that as regards quality, the plants herein would be very difficult to beat. Mr. William H. Duckham, who was under the renowned Chapman—happily still with us—at Weston-birt before coming to America twenty years ago, was first, and had a magnificent central wedge of Hippocastanums, rising backward and topped there with tall Acacias (*A. pubescens*), which had *Tropæolum Firefly* entwined among them. Pyramids of *Schizanthus à la* Messrs. Sutton and Sons, *Chorizemas* (superb little plants), bushy Bougain-

villas, *Cytisus fragrans*, Azaleas and such like were daringly and effectively blended. Other plants that were much employed in this and other of the groups were *Primula malacoides*, Darwin Tulips, *Cinerarias*, *Lilium longiflorum*, *Rhododendron Pink Pearl* and *Lily of the Valley*. *Pelargonium Clorinda* in 12-inch pots (very handsome plants), together with well-balanced, large-flowered Peach trees, Laburnums, Lilacs, Wisterias, and *Buddleia asiatica* were elsewhere noted; and it was indeed like old times to me to view and compare these charming groups.

The Rose gardens referred to were in purely geometrical form—little gardens in miniature, but well planned. One had a pretty white lattice-work fence or screen 10 feet high on three sides, with ornamental cornices and arched gateways, a sundial in the centre, a statuarial piece within one of the arches, and an artistic garden seat at one side. The wedge-shaped corner beds, as well as the round central bed and the borders, were daintily filled mainly with pink Roses, in which Tausendschön, as standards and bushes, figured prominently. Dorothy Perkins was trained to the screen. The other Rose garden was brighter, with crimson Hybrid Perpetuals, also Tausendschön, Baby Rambler and pieces of Katherine Zeimet. A rustic fir branch fence 2½ feet high surrounded it, and an arbour made gave "point" in one corner, while four walks branched from the centre bed. These were in flagstones, with smooth glen moss, representing sward, between and around them.

Roehrs' rockery was very modest as compared with our English rock gardens at the shows; but just think of the possibilities! Some friends here call me "the Narcissus Crank," because of my insistence upon the desirability of introducing more of the fine modern kinds here; but I have been even more insistent in the matter of rock gardening. All that is wanted here, methinks, is a selection of the proper plants for the climate; and surely the flora is large and varied enough to select from. Many of the alpine in this rockery were direct and recent importations from Mr. Amos Perry's nurseries, and Mr. J. Mallinson, who left Kew in 1902, arranged them in this rockery of his own building.

As for the other parts of the shows, they were good; none was poor. The retailers, or those we simply speak of as "florists" at home, who keep flower shops or stores, are more and more taking part in the large American horticultural exhibitions, and they were represented on this occasion with Italian pergola erections, Grecian cupolas, and so on, with their beautiful vases of resplendent Roses, Carnations, Antirrhinums, Sweet Peas, yellow Marguerites, Tulips, &c., as well as made-up pieces, bouquets and floral baskets. The public keenly enjoys these high-class displays. A novelty shown for the first time was in the form of dainty lace paper baskets about the size of one's two hands when cupped together, and they were filled with bright-leaved Rex Begonias, *Caladium Argyrites*, Ferns and Ericas. A demonstration and talk on floral arrangement was given one morning by Mr. Max Schling, a very talented Austrian, who comes of a family of architects in Vienna, and who has worked there and also in London. He is different from many retailers, who merely sell flowers as they would sell beef or mutton, and has a passionate love for them. He abjures wires and all that, and, while always "inventing" new floral arrangements, combinations and make-ups, these are always pieces of real artistry which even our English love of flowers *au naturel* could not but accept. This subject of the proper arranging of flowers and the use of them in all forms of decorations—personal, ballroom and others—is being studied most diligently and in great detail in America, and regular set courses are given by the floricultural departments of the agricultural colleges.

There is one point at the flower shows in America that could well be copied in England—especially if the exhibition extends over several days—and that is setting aside special days for certain flowers. A seven-day affair like the New York Spring Show would be a gigantic failure without these special exhibits. At first they seemed to me to be a nuisance, but now I appreciate their great value. The show opens with all its main features complete. Next day there are competitions for cut Roses. This brings in all the Rose people with their thousands of blooms. Some of the specimen plants of the previous day have been shifted into outer positions to make due space for the Roses, and the planning is so cleverly done that there is no crowding or questionable relegation of groups. Plants like specimen *Schizanthuses* do not look very fresh after a day or two on the floor, and can easily take a back seat. In their place come the cut flowers—one day, Roses, as mentioned; another day, Carnations; then Sweet Peas and Violets; on other days the tables of floral decorations are moved in, so that even if the visitor comes back day by day, there is something well worth his time to see.

This year, a great coup, so far as the success of the show was concerned, was made by giving a considerable space along one of the galleries to the Red Cross organisations. This was made into the model of a very pretty terrace garden, with a Vine-covered pergola over it, and borders of flowers and groups of shrubs about. Each day a distinct Chapter of the Red Cross League "kept house," dispensing tea and cake at a charge of one dollar for each person. All the great dames of the fashionable world of New York and environs took part, and by means of a remarkably well-organised publicity service, in which reporters, engaged by the flower show committee, supplied readable and very accurate reports of the day-to-day proceedings, interpolated with the names and doings of the society ladies—and gentlemen!—the whole Press of New York gave generously of its space to the show, with multitudinous photographs. So we have our "Temple Show" now, too.

J. HARRISON DICK.

THE GARDEN.

No. 2266.—VOL. LXXIX.

APRIL 24, 1915.

NOTES OF THE WEEK.

The Golden Valerian.—A large colony or a bed of *Valeriana Phu aurea*, with its rich low foliage, has a very telling effect at the present time. In fact, we do not know of any other plant that gives such a striking colour in the spring. It is therefore surprising that this Valerian is not more often met with. It loses its conspicuous colour during the summer, but now, mixed with such plants as red and blue Hyacinths, it makes a very attractive combination.

An Attractive Plant for a Warmhouse.—*Streptocarpus cyaneus* is one of the most charming plants of the whole genus. At the present time it is bearing its graceful flowers in great profusion. They vary in colour from pale lavender blue to rose pink or rosy mauve, and are generally borne in pairs. Like other members of the genus, it is short-lived, lasting little more than a biennial, and closely resembles *Streptocarpus Rexii*. It was first found in 1891 near Barberton, South Africa; but was later discovered at the Reef Bush in Swaziland, whence the majority of plants now growing in this country originated.

Pamphlet on Vegetable Cultivation.—Following on the other leaflets published last autumn and early in the present year, the Royal Horticultural Society has now prepared for circulation a pamphlet dealing with the cultivation of vegetables, principally in small gardens and allotments. The advice given is sound and useful, but we feel sure that the responsible will not misunderstand us when we say that its appearance is rather too belated to be of the greatest service. Had it been available in January, it would have been of considerably more service to the community than at this time. Even now, however, it is well worth the twopence asked for it.

Rosa sertata.—In the note that we published on this Rose in our issue for March 6, we stated that plants had been distributed by Messrs. James Veitch and Sons of Chelsea. Although to some extent, we are afraid that the statement has led to some misunderstanding. We have that seeds of this Rose were collected by E. H. Wilson for Messrs. Veitch, who sent the plant, under number, to Kew a few years since. Then it has flowered and been recorded in the *Botanical Magazine*, where Messrs. Veitch were given the credit for sending it to

Kew. We understand that plants were also received at Kew from Messrs. Vilmorin and Co. of Paris.

Springtime at Kew.—The wilder parts of the famous gardens at Kew are now resplendent with the gold and primrose of Daffodils, planted in the grass so as to give as natural an appearance as possible. That these are highly appreciated

Sparrows and Gooseberry Flowers.—We do not remember sparrows to have been so troublesome in the garden as they are this year. Crocuses, Chionodoxas, Polyanthus, Peas, and even the buds of Daffodils have been ravished by them, and now they are attacking the Gooseberry flowers. This, in our experience, is a new departure. Although we love birds, including sparrows, we have reluctantly come to the conclusion that sterner measures than black cotton and netting will have to be taken with these mischievous rascals.

Professor Keeble's Sad Loss.—We feel sure that horticulturists in all parts of the world will be deeply grieved to hear of the death of Mrs. Keeble, wife of Professor Keeble, Director of the Royal Horticultural Society's gardens at Wisley. Mrs. Keeble was seemingly in perfect health on Wednesday morning of last week, but was taken suddenly ill during the evening and passed away a few hours later. It is only a comparatively short time since Professor and Mrs. Keeble went to reside at Weybridge, so as to be near Wisley, but the deceased lady had already made many friends in the district. The deepest sympathy of everyone who knows him will be extended to Professor Keeble in his exceedingly sad and sudden bereavement.

Gooseberry Mildew in Cambridgeshire.—The Board of Agriculture and Fisheries have received information that the summer stage of American Gooseberry mildew (*Sphaerotheca Mors uvæ*) was discovered in a Cambridgeshire garden on the 10th inst. All Gooseberry growers are advised to examine their bushes carefully, and should any sign of disease be found, to spray their bushes with a solution of liver of sulphur (a pound to thirty-two gallons of water). A leaflet describing the disease and giving directions for dealing with it can be obtained from the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place,

London, S.W., gratis and post free. Letters so addressed need not be stamped. Growers are reminded that by Article 3 of the American Gooseberry Mildew Order of 1911 they are required to report the presence of this disease on their premises to the Board or the Clerk of the Local Authority for the district, either directly or through an inspector, and that the failure to report is punishable by a fine.

A SPRING SCENE AT KEW. DAFFODILS EFFECTIVELY GROUPED IN TURF.

is evidenced by the crowds of people who visited the gardens on Saturday and Sunday, the 17th and 18th inst. The illustration on this page, from a photograph taken on Thursday of last week, gives some idea of the excellent grouping of the Daffodils between and under lofty trees, where the greensward provides an ideal setting for the flowers. Pictures like this should be noted now for reference at planting time.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Tall Specimen of Mahonia Aquifolium.—

In one of the shrubberies here there is a plant of Mahonia (Berberis) Aquifolium over five feet in height. As I have never come across so tall a specimen of this shrub, I am curious to know if it is at all common for it to attain such a height. The plant is growing in heavy clay, and was planted by me thirty-two years ago. May it not be the result of a seedling, developing this tall form?—CHARLES COMFORT, *Broomfield Gardens, Midlothian.*

A Qualified Belgian Horticulturist.—Might I be allowed to call the attention of your readers to the need of a Belgian refugee, now working in our nursery, for a permanent situation, in which his rather unusual abilities would have fuller scope than we can give him? He is able to speak

to my thinking. But the ideal Hyacinths would have all the lovely hues and fragrance of the present garden ones, combined with the graceful form of the finest wild Bluebells. Such flowers would be a real boon at this time of year. The nearest I am able at present to approach this is to plant old bulbs of bedding Hyacinths along the edge of the kitchen garden, and by allowing them to remain undisturbed year after year they yield a number of small sprays, with which I fill bowls for the house. I have tried various kinds of foliage, but the prettiest I have this year seems almost too absurdly simple to describe, only the colour effect is so agreeably fresh and has been so much admired that I will dare to do so. The bowls are filled with some Festuca ovina (the fine bright green Sheep's Fescue Grass) taken up bodily, and the many coloured (or else all white) spikes of Hyacinth, with just a few of their own leaves, set therein. That is all.—ANNE AMATEUR.

A Dwarf Lilac Species.—The flowering shoot of which an illustration is given represents one

SYRINGA JULIANA, A NEW AND DISTINCT DWARF LILAC FROM CHINA.

French, Dutch, German, Spanish, Flemish, and has a knowledge of English sufficient to make himself understood. He has recently managed a large nursery near Antwerp, where some two hundred men were employed, and has been Lecturer at the Horticultural School, Vilvorde, Belgium, and elsewhere, and was for some time in Spain managing an experimental station. Any further particulars would be gladly supplied.—GEORGE BUNYARD AND CO., LIMITED, *Maidstone.*

About Hyacinths.—I want to enlist the sympathy of some readers of THE GARDEN with regard to Hyacinths, those flowers so lovely in colour and fragrance, but, as usually grown, so absolutely impossible (on account of their stiff, ugly, clumsy shape) in the house to any eye which demands beauty of form. I read in THE GARDEN recently that a famous firm of florists is going to give us Hyacinths with several light spikes instead of one orthodox large, awkward one. This is good news, and a step in the right direction,

of the dwarfest of the race and one that, although not particularly showy, is nevertheless very fragrant and interesting. It is quite possible that it may prove of considerable service to those who make a feature of raising hybrid plants. Writing of this in *Country Life*, Mr. W. J. Bean says: "Syringa juliana is a twentieth century introduction of Wilson from Western China. Although it has not the splendour of the common Lilac group nor rivals even the Persian Lilacs in beauty, it flowers freely, as our illustration shows, and it has, also, the characteristic and delightful fragrance of its race. The flowers are nearly white on the upper side, but beneath they are deep lilac, while the calyx is violet coloured, a striking contrast. The leaves are velvety, with down beneath. It commences to flower at 1 foot 6 inches to 2 feet high, and will not, I should say, grow more than 4 feet or at any rate 6 feet high. It likes a loamy soil and abhors drought."

Early Syringing of Roses for Mildew.—those excellent articles by Professor Houst last spring in THE GARDEN, mention was made by him of mildew living on the stems of Rose bushes all the winter. That being so, it seems well to remind readers—especially those who have had occasion to write so complainingly of the presence of mildew—that an effort should be made at this time of year to give the trees thorough syringing with a suitable fungicide. In their almost leafless state the wetting of the wood is an easy matter with a proper spray, while the good result should be quite obvious. Sulphide of potassium is acclaimed by pathologists to be one of the best, if not the best anti-fungal wash, applied usually at the strength of half an ounce to a gallon of water. But while the trees are quite dormant the strength might with advantage be increased to three-quarters of an ounce to a gallon; it will be more effective, and there is no foliage to fear of hurting. That is the proportion in which I have just been using it. There is no doubt that a large share of the mildew in private gardens comes in on fresh plants from the nurseries in the autumn, and if these are not dressed early in the year as above advised, mildew must be more rampant the following season. Only last autumn I was forcibly reminded of this fact by a batch of Rose plants we obtained to re-stock a bed. Though procured from a first-class firm there was no mistaking how badly they had been affected, and, of course, still had traces on the decaying flower-stalks and few remaining leaves. C. T., *Highgate.*

Vegetable Manure.—I should like to thank your contributor "Avon" for his letter in THE GARDEN for April 10, page 171, about my note on vegetable manure, published recently. I quite agree with him when he advises readers to burn as much rubbish as possible and spread the ashes for future use; but the results would be more satisfactory if the soil of the garden were treated with animal manure as well when it is being dug next autumn. Readers should remember that (although wood-ashes are most useful) to dress a big garden with ashes from a garden bonfire is not a substitute for animal manure, even if sufficient ashes could be stored. But well-rotted vegetable manure of the kind I outlined in my previous letter is not only a substitute, but a very good substitute, for animal manure. Vegetable manure supplies humus, and that is what many (especially light) soils require, and humus is the essential of all winter manuring of soil. We can have the most perfectly compounded artificial (*i.e.*, chemical) fertilisers, but that is not to my mind, can only very rarely be used with manure in winter digging. Humus is not supplied by any real chemical fertiliser, and as the ultimate source of humus (*i.e.*, stable manure) will be inadequate for obvious reasons to meet the demand this year, I recommend vegetable manure to be used instead. As "Avon" remarks, the method will be somewhat of a nuisance in some places, but there are, I feel certain, many others where it could be managed. With regard to salt lime, the former might be used, seeing that it kills insects and their eggs; but lime is used to keep down any unpleasant smell as well as the above. We do not, of course, put Cabbages and the like in with the rubbish for vegetable manure; soft material alone is used as previously pointed out. Cabbage and other stuff are burnt to ashes with Ivy clippings.—F. ELLIS, *Weetwood, Ecclesall, Sheffield.*

Hurdle for Shelter.—If your correspondent, whose letter appears on page 170, issue 10, will closely examine the hurdle illustrated in the issue dated March 27, will see that it is not the ordinary sheep hurdle, but a hurdle, which has been in existence for the last thousand years, one might truly say. I do not say that even this type of hurdle, which is very popular for sheltering plants, has not been made also for many years; but I do say there are thousands of readers to whom this hurdle was not known, and it is for these that I write.—E. MOLYNEUX.

Potato Warwick Castle.—The advantage of the new second-early Potato lies in the fact that, apart from its heavy cropping quality, its cooking is not impaired by keeping. When dug in August, it was excellent, and now—early in April—it is even better, if possible. The flesh is white, firm, and of very good flavour. The pebbled tubers are large and handsome, with that high exterior which denotes quality within. The firmness, too, of the skin at this season without special preservation is remarkable. As a potato I think most highly of the new-comer. Those who have not grown this variety should take no time in adding it to their list, either as a second early or for late use.—E. M.

Some Beautiful Hardy Primulas.—Two very beautiful dwarf Primulas in flower at the present time are *Primula Kellneri* and *P. hirsuta* Mrs. J. H. Wilson. The former has smooth, dark green leaves, somewhat glandular. Borne quite singly on stems about two inches long are lovely, crinkled, claret rose coloured flowers with white centres, like so many five-pointed stars. This plant is said to be a natural hybrid of *P. hirsuta* crossed with *P. minima*, and is sparsely distributed over the Brenner Pass. In striking contrast to many rare plants, Mr. Reginald Kellner, in speaking of this group of Primulas, says: "All these in the garden are not only the most gratifying heartiness, but are also—especially *P. Kellneri*—of an even greater generosity in the way of flower than they are on their own native hills." Plants divided last year are thriving here in a loamy soil, and seem to succeed equally well in either semi-shade or any position. *P. hirsuta* Mrs. J. H. Wilson is often spoken of, though in error, as a variety of *P. viscosa*. Its leaves are longer than the preceding, and of a lighter green colour; in fact, the plant is larger in all its parts with the exception of the flowers, which, though more numerous, are not individually quite as large. They are borne profusely in trusses of violet purple, with well-defined creamy centres. Both the above are of easy culture, and are worthy of being more widely known and grown.—JOHN G. BROADHEAD, *Goldale Nurseries, Thongs Bridge, Huddersfield.*

A Rare Plant in Scotland.—Nearly sixteen years ago I wrote a note on *Carduncellus pinnatus*, which was published in THE GARDEN on October 7, 1899. I have had the plant in my garden all that time, and I can state with all confidence that it is one which I never tire of possessing, though it never gives many flowers at a time. It first came to me through the kindness of Sir Frederick Moore, on my expressing my admiration for the *Carduncellus* when seeing it at Snevin for the first time. Then the plant was far from common, and it appears to be as rare as ever now, as I never meet with it in the garden, except in those to which I have sent it. In 1899 I described it as a plant about three inches

high, with pinnate leaves and with a flower like that of a Cornflower borne singly in the centre of each tuft of the plant; this flower is of a light purplish blue. I can only correct what I said by stating that the height is sometimes a little more than three inches. As I remarked when writing about *C. pinnatus* at that time, its fault is that of producing few flowers, and I have never obtained more than a few at a time, even on good-sized plants. It is an easy plant to grow, and thrives well with me on a light soil, both in the rock garden and in the border. It spreads freely at the roots, yet not so rapidly as to be a menace to other flowers. Its seeds freely, but much of the seed appears to be infertile with me. *Carduncellus pinnatus* is one of some fourteen species named in the "Index Kewensis," and is synonymous with *C. acaulis*. It is vaguely reported to be from the East.—S. ARNOTT, *Dumfries.*

Bulbs for Spring Planting.—The article on the above on page 165, issue April 3, ought to have awakened interest among those who labour under the impression that, apart from *Gladioli*, *Begonias* and *Anemones*, there are no bulbs except *Daffodils* and others that flower in spring. It might be pointed out that *Gladioli*, *Begonias* and *Anemones* are not strictly bulbs. This, however, is a mere detail. The point is to encourage the planting of bulbs, tubers, corms and rhizomes that yield a crop of flowers during the summer months. Such bulbs are, for the most part, all available for spring planting. Dry roots of *Dahlias*, either the pot-grown sample or full-sized roots, will flower earlier and make a bigger show than spring-rooted cuttings if planted dormant in April. *Cooperia pedunculata* is a charming little white star-like flowering bulb. It is a Texas plant that opens its flowers in the evening. *Anomatheca cruenta*, bearing red *Freesia*-like flowers, blooms very freely. *Bravoa geminiflora* is quite a stranger to most gardeners. It is a Mexican bulb, sending up tall spikes of coral red, tubular flowers. The bulbs are hardy in some districts, but the safest plan is to lift and store them in fibre or sand. This bulb has fleshy roots, which should not be dried off. It can be raised from seed quite easily, but as the bulbs can be obtained from bulb merchants at 2s. a dozen, raising from seed is scarcely worth while. It is a charming summer bloomer that ought to be better known. The various *Crinum*s are all available for spring planting. *Bessera elegans* and *Milla biflora* are both charming little bulbs from Mexico that are easily flowered; they cost but little. The Peruvian *Daffodil* (*Ismene calathina*) bears beautiful white flowers, and, if planted deeply, it need not be lifted in the autumn. Strong bulbs only cost about 2s. 6d. a dozen. *Watsonia Ardernei* is another delightful bulb, giving spikes of white flowers. *Rigidella immaculata* bears scarlet flowers, and calls for no special treatment. *Cypella Herbertii*, treated like a *Gladiolus*, yields very pretty yellow flowers, and few people know it. Indeed, one might easily extend the list of bulbs that will give a display if planted now. Moreover, many of these bulbs would prove a delightful surprise.—T. A. W.

FORTHCOMING EVENTS.

April 27.—Royal Horticultural Society's Meeting and Exhibition and the Auricula and Primula Show, Vincent Square, Westminster.

April 29.—North of England Horticultural Society's Show and Perpetual Flowering Carnation Society's Exhibition at Leeds (two days).

THE BEST HARD-WOODED PLANTS.

COMPARATIVELY few hard-wooded plants have been shown at the recent meetings of the Royal Horticultural Society, but included in that limited number are some remarkably attractive subjects. Taken altogether, hard-wooded plants in general are so beautiful that one cannot help regretting that they are now so little grown. The reason of their present-day neglect is, I think, to be found in the fact that their flowers are not large (as size counts for a lot with most people), and also that they need a good deal of care and attention in all stages of growth. Probably at some future time hard-wooded plants may again come into their own. Meanwhile, a note on a few of those that still retain their popularity, and also on some that might with advantage be more grown, may not be out of place.

Greenhouse Heaths.—The species and varieties of greenhouse Heaths used at one time to be reckoned by hundreds, most of which have practically disappeared. Still, a few of our market cultivators grow large quantities of a limited number of kinds, chief of which are *Erica candidissima*, white; *E. caffra*, white; *E. cavendishiana*, yellow; *E. gracilis*, rosy purple; *E. g. nivalis*, white; *E. hyemalis*, rose and white; *E. h. alba*, white; *E. melanthera*, pale mauve; *E. persoluta* alba, white; *E. propendens*, lilac; *E. spenceriana*, rosy lilac; *E. ventricosa*, purplish red; and *E. willmoreana*, reddish rose. Several of these kinds have been exhibited of late, and many of the plants showed evidences of great cultural skill.

Boronias, too, are another genus of hard-wooded plants that are still extensively grown. The first to bloom—for its earliest blossoms expand soon after Christmas—is *Boronia megastigma*, remarkable for its delicious fragrance. Being brown outside and yellowish within, the flowers are not particularly showy, but their sweet scent well compensates for this. The next to flower is *B. heterophylla*, which is, like the preceding, a favourite with the market cultivator who makes a speciality of this class of plants. The blossoms of this are of a bright carmine rose colour. Later than either of these two comes *B. elatior*, with rosy red flowers. A very distinct species is *B. serrulata*, but it is now very rarely seen, though Messrs. Balchin, when at Hassocks, used to grow it remarkably well. They were also noted for the charming blue-flowered

Leschenaultia biloba major, which has never been shown in such good condition as it used to be from that Southdown nursery. The scarlet-flowered *L. formosa* seems to have almost, if not quite, dropped out of cultivation.

Azaleas are still extensively grown, though not in the shape of large specimens as they used to be. They have been this season remarkably fine; but as nearly all our plants are imported from Belgium, a shortage may reasonably be anticipated during the forthcoming autumn.

Acacias.—The smaller-growing *Acacias* that can be flowered successfully in pots are, in some cases at least, freely grown. This is doubtless to a certain extent owing to the fact that they are far less particular in their cultural requirements than the majority of hard-wooded plants.

Besides those before mentioned, the following are all worthy of occupying once more a prominent place in our gardens:

Aotus gracillima.—A loose, graceful-habited shrub, whose long shoots are densely clothed with small, Pea-shaped, yellow and crimson flowers.

Aphelexis.—A pretty class of Everlasting Flowers now included in the genus *Helichrysum*. They are of a dwarf, shrubby character, with the stems and young leaves clothed with a hoary tomentum. The flowers, borne on the points of the shoots, are in *A. humile* of a delightful shade of satiny pink, while in *A. macrantha purpurea* they are of a deeper tone.

Chorizemas.—These are met with more frequently than some of the others, and their bright-coloured, Pea-shaped flowers make a goodly show in the greenhouse early in the year. The best variety for comparatively small pots is *C. Lowii*.

Correa (Australian Fuchsia).—The showiest of the *Correas* is *C. cardinalis*, whose drooping, tubular-shaped blossoms are borne in the winter and early spring.

Crowea.—There are two species of this genus, namely, *C. saligna*, which blooms in the autumn and winter; and *C. angustifolia*, which flowers in the spring. Both have pink blossoms.

Diosmas.—Pretty Heath-like plants with fragrant foliage and little terminal heads of blossoms, white, bluish or mauve in colour.

Epaerises.—These are certainly grown more than some of the plants herewith mentioned, but they are not so generally met with as their merits entitle them to be.

Eriostemon.—All the members of this genus form neat bushes, which in the spring are thickly covered with white starry blossoms.

Hovea Celsii.—A leguminous shrub of a rather rambling character, with Pea-shaped blossoms of a beautiful blue tint. It needs careful handling, and used to be regarded as a good test of the cultivator's skill.

Pimelias, with their heads of pretty, light-coloured flowers, were much grown in the olden days, but are now seldom seen.

Polygala dalmaisiana.—The rich rosy purple blossoms of this *Polygala* gain it many admirers when in flower, which is during the spring.

Platythea galioides, also known as *Tremandra verticillata*, is a slender-growing plant with linear leaves disposed in whorls. The saucer-shaped, drooping blossoms are of a delightful shade of blue. This list might be considerably extended, but lack of space prevents.

It may be noted that practically all of these hard-wooded plants have fine, delicate roots and need a compost mainly consisting of peat and sand. Potting must be firmly done, and watering at all times carefully attended to.

H. P.

CHINA ROSES.

I HAVE an idea that the exquisite, old-fashioned Roses which bear this distinctive name are in danger of being ignored. Yet it cannot be questioned that some of their modern representatives are sufficiently effective, in their form and colouring, to preserve this charming race of fragrant Roses from premature extinction. Many of them are as delicately tinted as the Teas or even the *Rosa pernetiana* creations. Since the memorable days

fascination are *Comtesse du Cayla* (recently added to my highly attractive collection in the garden at Kirk House, where Roses of all kinds are growing most vigorously), *Mme. Eugène Resal*, a lovely combination of delicate pink and orange; *Mrs. Edward Clayton*, *Fellenberg*, *Jean Bach Sisley*, and the refinedly beautiful *Mlle. de la Vallette*. These fascinating Roses are of such almost inestimable value by reason of the attribute we term perpetuity, and which the French with even greater expressiveness call *remontante*, that they should be cultivated assiduously and lovingly in every Rose garden that is worthy of the name.

DAVID R. WILLIAMSON.

Wigtownshire, N.B.

THE NEW BORDER CARNATION DAISY WALKER. THE FLOWERS ARE WHITE FLAKED WITH ROSE SCARLET.

A GOOD NEW BORDER CARNATION.

THE fancy class of the hardy border Carnation has a valuable addition in the variety *Daisy Walker*, illustrated on this page. This received a first-class certificate from the National Carnation Society, London, winning also in its class the Cartwright Challenge Trophy for its perfect border habit. It has a pure white ground, lightly and beautifully marked with rose scarlet. The flowers are very large, of perfect form, and borne erect on very stiff stems. All border Carnations should be of such sturdy habit that little or no staking is required. Mr. James Douglas, the raiser and introducer of *Daisy Walker*, now insists on all novelties having this desirable characteristic; otherwise, however fine the blooms may be, they cannot rank as improvements on the older varieties.

THE WHITE-FLOWERED LAVENDER.

To some people the metallic blue tint of the ordinary Lavender flowers is half their charm, but others appreciate deviations from the normal, providing such changes are in harmony with the general character of the plant. A variation of this kind will be found in the white-flowered Lavender, *Lavandula Spica alba*,

when the late Dean Hole of Rochester sang the praises of the "Brave Old Monthly," the China Roses have made a very remarkable advance in the direction of artistic perfection.

They were always of great value by reason of their vigour, their wonderful refinement of aspect and their splendid floriferousness; but of late years their progress in intensity and distinctiveness of colour has been especially observable. For a long period the fine variety entitled *Laurette Messimy* (which may be said to have created a kind of sensation on its first introduction) was one of my favourite varieties, and it still receives every attention in my garden. But of even greater

a plant that has been known for some time, and yet which, for some reason or other, is by no means extensively grown. That this should be so is difficult for one who has grown and appreciated the plant to understand. It is nearly, if not quite, as fragrant as the ordinary Lavender, flowers freely and possesses a good constitution. In all gardens where common Lavender thrives, the white-flowered variety may be relied upon to do well, and at least a few plants should be grown. The blossoms are not the pure glistening white that we find in the *Snowdrop*, but rather a sort of greyish white. They are, however, quite distinct from those of the ordinary Lavender.

H.

THE HEATH GARDEN IN SPRING.

THERE are few more pleasing features in the outdoor garden at any season than the home of the hardy Heaths. In midwinter, as we have on more than one occasion shown in these pages, there are several kinds in flower, and the display is continued by others right through the spring, summer and autumn. Just now there are several very beautiful kinds in flower, the most charming of all being the so-called Winter Heath, *Erica carnea*. Although the flowers of this actually open during the waning days of winter, it is not until spring is here that their full beauty is revealed.

It is a generally accepted belief that *Ericas* and other peat-loving shrubs of the same Natural Order, such as *Rhododendrons* and *Azaleas*, will not thrive over soils containing lime or chalk. In this bright rose-coloured Heath we have a notable exception, for even though it shows preference for a sandy peat or loamy soil, it will, nevertheless, thrive in a soil rich in chalk or limestone. In Lord Sherborne's garden, situated in the middle of the Cotswolds, where the soil is nothing but limestone, this accommodating Heath spreads rapidly and flowers abundantly. This is a point worth noting, and those who have not yet been successful in the cultivation of Heaths should not despair before giving *Erica carnea* a trial. It is a low-growing species not exceeding 6 inches in height, and when established never fails to display a carpet of bloom in the springtime. It is an admirable subject for planting in the foreground of the rock garden.

A taller species that is now very beautiful is *Erica mediterranea*. This must not be confused with *mediterranea hybrida* (now named *darleyensis* at Kew), which flowers in midwinter and is of much dwarfer habit. *Mediterranea* proper makes a more or less erect bush several feet in height, and in April is freely bespangled with its pink flowers, which are delightfully fragrant. It is a native of the south-west provinces of France and Spain. There is a white-flowered form of it named *alba*, which makes a rather more compact bush and is not so good as the type. The Tree Heath, *Erica arborea*, has nearly finished flowering.

It was introduced from the Mediterranean and Caucasus as long ago as 1658, and is to be found in a good many gardens. It forms quite a large shrub, sometimes as much as 20 feet in height, and is usually freely clothed with its white blossoms in early spring.

Very similar in appearance is the Portuguese Heath, *Erica lusitanica*. It flowers at the same time, and in most gardens is now past its best. A very pretty Heath that many find difficult to grow is *Erica australis*. It also is a native of Portugal, and although of rather a loose, ungainly habit, is well worth trying on account of the colour

of its flowers; this is a charming shade of rose red.

This Heath flourishes in many Cornish and other West Country gardens, where it attains a height of 5 feet; but one does not often see good plants in the London district. Just now it is at its best, so far as flowering is concerned. The foregoing may be regarded as the best of the spring-flowering Heaths; those that blossom in summer and autumn will be described later.

ERICA.

PRIMULA INVOLUCRATA

THIS dainty *Primula* rejoices in a moist position in the rock garden. It is a native of the Himalaya, producing fragrant, creamy white flowers borne on slender stems well above the rosettes of bright, shiny leaves. This year it has flowered with remarkable freedom. Moisture is essential for the well-being of this species, and it will thrive even in a bog

PRIMULA INVOLUCRATA, A BEAUTIFUL HARDY SPECIES WITH CREAMY WHITE FLOWERS.

garden. It is seen to best advantage when grown under similar conditions to the beautiful *Primula rosea*—that is, in peaty soil by a stream in the lower parts of the rock garden. Here the plants will thrive and flower during May and early June. There is, however, just a risk of losing the plants in the winter, when, as in the case of many other *Primulas*, the rosettes of foliage die down. This is obviously a *Primula* to plant in little colonies, for isolated plants seem lost when planted out in the rock garden. Our illustration depicts a small colony of this *Primula* effectively grouped by Mr. Clarence Elliott in his rock garden exhibit at the Chelsea Show held in May last, when it created a considerable amount of interest among connoisseurs of hardy plants. We wonder what the prospects of the Chelsea Show for this year are. So far as we can ascertain now, the rock and other gardens will be considerably curtailed.

THE ROWAN OR MOUNTAIN ASH.

ON the Scottish mountains one may often find beautiful effects formed by wild trees of the Mountain Ash, sometimes growing alone, but more often in the company of Birch, Scots Pine and wild Juniper. The trees are sometimes in fair sized groups, particularly when growing on the gentler slopes and in the valleys, but when growing upon precipitous mountain sides or among the crags of almost perpendicular walls of rock they more often occur as scattered, isolated trees or in clusters of two or three. Wherever found, however, they appear to occupy the right position, and in the autumn, when covered with bright red berries, add much assistance to the Heather

and other plants which are responsible for so great a share of the wide-famed autumn beauty of the Scottish Highlands.

Under natural conditions the Mountain Ash is usually smaller than when growing in gardens, and is often found as a bush or small tree below 15 feet in height, altitude, poor soil and exposure being responsible for reduced growth, although there are few places where tree growth is possible that it absolutely refuses to thrive.

In gardens it is a great favourite, for not only is it attractive in May when covered with its dense heads of white flowers, but the leafage is distinct among other trees, and there are few species with such brilliant fruits. In some parts of England it is used effectively on the outskirts of plantations, but not so often as its value warrants, and more extensive plantings might be made with advantage. Any trees and shrubs of the right types which harmonise with our

native trees may be used for the outer parts of plantations, where those with brilliant fruits or autumn foliage serve to brighten the landscape by creating patches of brilliant colour among the sombre-hued Pines and other trees of that class which are so often planted for silvicultural purposes.

Moreover, the wood of the Mountain Ash is valuable for various kinds of work, although it is not obtainable in sufficient quantity to make it a commercial success at the present time. Being hard and close-grained, it is useful for turning, and with other kinds of *Pyrus* wood may be used for many small articles. The typical *Pyrus Aucuparia*, the common Mountain Ash, is not, however, the only kind available for planting. Horticulturists have selected a number of kinds for varietal names, which are really better than the type for garden purposes. The majority are distinguished by differences in the size or colour of the flowers, but a few exhibit differences of habit or foliage. In the succeeding

essential to the most effective weeping trees. *P. A. asplenifolia* differs from other varieties by having the margins of the leaflets deeply cut, a curious little lobe often being present at the base of each leaflet. *P. A. laciniata* also has its leaflets deeply lobed. Both have red fruits. *P. A. Dirkenii aurea* has yellow variegated leaves. It cannot, however, be regarded as an important variety, for the golden colouring is not really first-rate. The American Mountain Ash, *P. americana*, is also worth attention, and in many ways is quite as beautiful as our native tree. Its berries are, if anything, larger than those of the common Rowan, and are borne in larger heads. The variety *nana* is, however, preferable for most gardens. Of lower stature than the type, it is, nevertheless, of vigorous growth and compact habit. Its branch system is stiff and upright, its leaves dark green and of a peculiarly healthy appearance, while its large, bright red fruits are borne in bunches which are often 9 inches across. The common Mountain Ash is easily

make the most of. For adding charm to the tiny pool or more majestic lake they have no peer, and as they are not difficult to cultivate, if not actually to perfection, at least to a high degree, we may reasonably expect in a few years' time to find them much more widely grown than they are at present.

There are, however, a few essentials to success. Almost still water is necessary, as also is a sunny position. If in partial or permanent shade, the flowers do not open freely, and consequently much of their beauty is not revealed to the observer. Shelter from strong winds should also be aimed at. I know of few plants that look more miserable when tossed about by boisterous winds, and often considerable damage is thus caused to the large leaves, which, when well preserved, are in many instances second only in beauty to the flowers themselves. Then, the grouping of the plants needs some little care. Generally speaking, formality should be avoided like the plague; a water garden must, above all else, be informal,

or as Nature herself would have it; hence straight rows of plants, well grown though they may be, can scarcely be said to exhibit that informal grouping that one has in mind as being so desirable.

Undoubtedly the best time of the year to plant these Water Lilies, and, incidentally, to divide any that need it, is from the middle of April until about the third week in May. At that time new growths begin to get active and the plants quickly establish themselves in their fresh quarters, and consequently receive the least possible check. Whether or not an established plant needs lifting and dividing is a question that must be determined on the spot. If a plant has obviously become overgrown and congested, as exemplified by crowded leaves and stems and few flowers, then such a course is necessary and desirable; but with a great many of the newer hybrids such measures are seldom called for. So long as a plant is healthy and producing each year a reasonable quantity of good flowers, it is a golden rule to leave it well alone. When

division is done, a strong crown and some roots should be secured to each portion, a sharp knife being used to cut through the thick tuberous-like rhizome that is characteristic of many varieties.

Reverting to the actual planting. Having determined the depth it is desirable to submerge the plants—this ranging from 18 inches to about six feet, according to the variety—some preparation of soil and receptacles for the plants must be attended to. Mr. James Hudson, V.M.H., the well-known head-gardener at Gunnersbury House, who grows these Water Lilies better than anyone else I know, uses Strawberry punnets for the small plants that are usually received from the nursery, and the large wicker sieves or nursery rounds for plants of more ample dimensions. These, in the course of a year or two, decay, but meanwhile the roots have been able to find their way through the wicker-work, and the plants are therefore by that time quite able to take care of themselves. So far as soil is concerned, one

NYMPHÆA MARLIACEA ROSEA, A BEAUTIFUL AND FREE-FLOWERING HARDY WATER LILY.

notes attention is directed to a few of the best: *Pyrus Aucuparia moravica* is a very fine fruited kind, its rich red berries being larger than those of the type. The growth is very vigorous, and the handsome leaves 9 inches to 12 inches long with red midribs. It is one of the best of all. *P. A. discolor* is distinct by reason of its orange-coloured berries, which appear in large clusters. A very distinct variety with yellow fruits is found in *P. A. fructu luteo*. This should always be grown as a well-marked kind. *P. A. integerrima* is useful for gardens of restricted area, for it is of close, fastigate habit, with the appearance of a dwarf Lombardy Poplar. The berries are red and borne freely. *P. A. satureifolia* has some affinities with the yellow-berried Rowan, for its fruits are a similar colour, but the bunches are larger and the tree rather more vigorous. *P. A. pendula* and *P. A. p. Dawsonii* both have a pendent habit, but neither is a really handsome tree, for the poise of the branches is such as to preclude the degree of gracefulness which is

raised from seeds, while the different varieties are grafted or budded upon stocks of the type. W. D.

PLANTING THE HARDY WATER LILIES.

IN those gardens where comparatively still water exists, there are few more interesting operations during the spring months than the planting of hardy Water Lilies or *Nymphæas*. To those who only know the family by the white-flowered British species, beautiful though it is, the many lovely, gloriously coloured hybrids that are now obtainable will come as a pleasant and interesting surprise. Sufficiently hardy to withstand our ordinary winters with impunity, and embracing varieties suitable for deep and shallow water, these comparatively new Water Lilies hold possibilities that the average gardener of to-day does not

cannot do better than give Mr. Hudson's recipe, which is as follows: A layer of decayed leaves is first placed over the bottom of the basket, then some broken-up turfy loam of good quality, with some road scrapings added, and into this the Water Lilies are planted and tied so that they cannot escape while the baskets are being submerged.

There are now a great many varieties obtainable, some with yellow flowers, others with varying shades of red, and others, again, with blush pink blossoms. All are beautiful and hardy, and names with descriptions can be obtained from any good catalogue of hardy plants for spring planting. F. W.

DAFFODIL NOTES.

BY THE REV. JOSEPH JACOB.

"London, 1915."—The contrast between the outward circumstances of this year and last could not well be greater; lateness instead of earliness, and war in the place of peace. Truly, "one never knows." Poor "London" has had a rough start in life. First, the setting of its house in order; then a series of super-abnormal seasons; and now, to cap all, the horrid anxiety inseparable from a gigantic national conflict. No one can have expected a large show. I think everyone felt that it was something to have one at all when so many others have had to be abandoned, for Lincolnshire and Presteign must now be deleted from the list I gave some weeks back in my notes. Let us hope that in the time to come we may be able to refer to 1915 as "the war year," and not have to couple 1916 with it and speak of "the war years." Two very important matters came before the committee.

Registration of Names.—I promised to report when the question was finally settled. In future no name will be registered unless accompanied by a fee of half-a-crown, and unless an official form giving certain details about the flower has been filled up. All these new additions to the list are to be marked with an asterisk.

It is impossible to forecast with any certainty what the practical outcome of this momentous change will be. Some think it will cut off the supply of names altogether; whereas others, and myself among the number, hope that it will effect the much-needed reform, and that only those varieties that are likely to be seen on the show tiers or in our gardens will be registered. This would extend the sphere of its usefulness considerably, for it would be equivalent to a kind of minor award, inasmuch as it is natural to suppose that only a raiser's best will be registered. Here again, of course, it must be remembered that one raiser's best may be another's worst. This cannot be helped; it is the price that has to be

paid for catholicity of taste. There is one very important proviso with regard to the flower that is registered which will ensure, as far as is possible, the name standing for a reality, *e.g.*, within a period of five years from the date of registration that flower must be actually shown, and a notice must be sent to the secretary of the committee to that effect.

The second subject is the division of the Leedsii, Class IV, into two divisions to correspond to the division of the "cups" into incomparabilis and Barrii. Mr. C. L. Adams, the hon. treasurer of

opportunity to reintroduce the name Engleheartii again, and I would propose it for the large-cupped varieties. One would then be Engleheartii and the other Leedsii. For the employment of the old word I would urge (1) it is an honour I would like to see paid to the Rev. G. H. Engleheart; (2) that by adopting one word we get in line with the other classes, *e.g.*, Barrii and incomparabilis; (3) that they are of such a distinct type that a new word is better than our old description Giant Leedsii. Against its adoption I can only see the possible mixing up of the old flat eyes like Incognita or Sequin with the revived name.

Trade Exhibits.—No exhibit can ever take the place of one of Engleheart's. The old associations which centre round the dead white backgrounds which our Master in Israel of late years always selected as a foil for his polished gems were on this occasion broken. It was not the war, I regret to say, that made the break necessary on his part. It was "doctor's orders," a much more serious matter for us Daffodil people to contemplate, for the ordered one is no longer in the heyday of youth, and the strain of a long day at the Hall is beginning to tell. Although for once we have been unable to express our appreciation of his efforts in a tangible way like we generally do, let me assure him that it is none the less real if it has not the visibility of a scrap of paper nor even the hieroglyphical markings that must have so often made the well-known little pocket-book such good reading when he got home.

We had no group either from Mr. A. M. Wilson, but we were more than compensated for the omission by seeing him in our midst in excellent health, and by his playing the difficult part of *backbone* to the competitive classes. The following firms put up their usual style of groups: Barr and Sons, Robert Sydenham, Limited, Christopher Bourne, Cartwright and Goodwin, Walter T. Ware, R. H. Bath, Limited, and James Carter and Co. Mr. Bard of this latter firm must appreciate a parson's difficulty in having

to put the old story in a different dress every Sunday for the same people. He has to do something akin to it in the Hall. After that wonderful orchard-like display (which, by the way, is figured in the "Daffodil Year Book" for 1914) at our last great show, and after his beautiful Crocus creations of this present season, I suppose I expected too much. It was very good, but again like us parsons, even a genius like my good friend cannot always be at his very best. The general idea was a lawn with King Alfreds in the grass, bounded by a raised border wherein were massed blocks of yellow and white Daffodils in front of close

NARCISSUS WHELP, A BEAUTIFUL SMALL-CUPPED VARIETY, SHOWN BY MR. P. D. WILLIAMS AT THE LONDON EXHIBITION.

the Midland Daffodil Society, brought the matter forward and explained the reason for the change. He found a very sympathetic committee, and the proposed change was unanimously agreed to. I presume that the final stage will be its passing the Council and the formal notification to the committee. Writing in the train on the way to Tewkesbury, where I am to act as judge, I am unable to state decidedly what I believe to be a fact, *viz.*, that there was nothing in the proposition as to the names of the two divisions. As these notes will be read before the next committee meeting, I would suggest that it might be an

growing evergreens, the whole being held in position by a low stone retaining wall.

Messrs. Barr and Sons' exhibit was a particularly fine one, well set up and rich in "good things." Had a gold medal been awarded, it would not have surprised me. Ten years ago half-a-dozen would not have been a sufficient recognition of its merits. Few probably—even Daffodil people—were aware that it helped to mark the beginning of a new era, inasmuch as only once before and on the present occasion, when the Hon. R. J. Seddon again appeared in public in the competitive classes, have we had Australasian-born blooms set up in a trade group in the ordinary way, as it were, without note or comment. Did Professor Thomas of Auckland see that lovely vase of Mrs. D. V. West from the great big island just a little nearer to the Equator than his own? I cannot say, nor, if he did, what he thought of it. However, I do know this: that two very keen gardeners indeed—one an Orchidist and the other a Montbretian—each made a list of the three or four most pleasing varieties which they would like to buy, and that Mrs. D. V. West and Bernardino were the only common factors. Mr. West, I congratulate you; and may your success stimulate other raisers in the dominions down below to send us more of their best, and our own people to grow and stage them.

Mr. C. Bourne, R. H. Bath, Robert Sydenham, Limited, Walter T. Ware, Limited, and Cartwright and Goodwin each had groups of interest. It is very evident that before we are many years older, both Walter T. Ware and R. H. Bath are going to show us some fine seedlings of their own manufacture. Their advance guard was in evidence last week.

Two Grand Flowers.—There were some excellent blooms scattered among the different competitive and trade exhibits. The two whose likenesses are given were those which were picked out by one of our leading fanciers as the two best in the show. Without entirely subscribing to that verdict, I can honestly say they were very good indeed, but I would have to bracket others with them were I to call them the best.

Alchemist, which was exhibited by Mr. A. M. Wilson, is a fine large, clear-cut, deep yellow trumpet variety. In depth of tone and smoothness of texture it has but few, if any, superiors.

Whelp, shown by Mr. P. D. Williams, is a grand small-cupped variety (Barrii) with a great expanse of white perianth, which slightly recurves, and a fluted yellow eye with a narrow edge of red. D, $3\frac{1}{4}$; S, $1\frac{1}{2} \times 1\frac{1}{4}$; C, $\frac{7}{8}$. One has seen this flower on several occasions, but never in such superb condition. See illustration on page 199.

In my next notes I hope to give a long list of from twenty to twenty-five of the most striking flowers in the Hall.

THE COLLARETTE DAHLIAS

ON all sides from those who have grown Collarettes nothing but praise is heard. It seems exaggeration to speak of these plants being in constant growth and flowering perpetually; yet such is the fact. A herbaceous border containing half a dozen clumps of Collarette Dahlias is in October, as in August, radiant with their beauty when all else except Michaelmas Daisies has faded. As a garden decorative plant this type of Dahlia surpasses all others, and is altogether most useful, being bushy in form, moderate in height and carry-

opened will last from a week to ten days in water. Of cultural details, suffice it to say that the Dahlia is most amenable to cultivation, revelling in a well drained and manured clayey loam, and it responds to every care bestowed upon it. It can be grown in many positions, and is most effective in clumps on lawns, or it flowers profusely between shrubs, while it is most useful in the herbaceous border, forming patches of colour when other perennials are over.

Of the varieties now grown, a number stand out prominently above the others. Chief among them are: Frogmore, the very best at present grown, a yellow ground splashed with vermillion,

with a yellow collarette. This leaves nothing to be desired in form and colour of flower, while the habit of the plant is vigorous, erect and bushy, producing long-stemmed flowers with a freedom without parallel. Queen Bess, an orange scarlet with yellow collarette and slightly star-shaped, flat-petalled flowers, comes second in point of freedom of flowering and artistic effect. Balmoral is a very showy and effective variety with long-stemmed flowers of bright puce colour, with a white and rose striped collarette. Princess Louise, a very distinct variety of especially dwarf habit and very free-flowering, has petals of rich glowing crimson and a white collarette. Negro, a maroon with white collarette, has a good stem and blooms very freely. Probably the best word to use for Henri Farman, a bright vermillion edged with primrose, with a straw-coloured collarette, is "grand." This variety is exceedingly showy, and should be widely known.

Of the newer varieties to be sent out this spring, some are sure to gain wide popularity. Messrs. Dobbie and Co. are offering twelve new ones, and various firms also are sending others, so there will be a wide field for choice. From notes gathered, the following six, in the writer's opinion, will surpass any yet grown: Tuskar, a deep crimson with white tips, an excellent grower, carrying an abundance of magnificently-formed blooms. Undoubtedly Prince of Orange will be adjudicated the finest of all Collarettes, very free-flowering, with flowers, as its name implies, of deep orange. The best of its colour yet seen. Skerryvore, a wonderfully

free-flowering and beautiful variety. Eddystone, a crimson with yellow tips. Pladder, a shady maroon carrying well-formed flowers with a fine stem. Inchmarnock, the nearest approach to a scarlet yet obtained, is excellent in form and colour, and a splendid grower. The foregoing descriptions are made up from notes taken on the Dahlia-beds (when the writer singled out the six from the many varieties on trial), and may not quite coincide with the raisers' descriptions given in catalogues when issued, but every variety is in advance of any at present grown, and deserves a trial.

S. W.

NARCISSUS ALCHEMIST, A FINE NEW YELLOW TRUMPET VARIETY SHOWN BY MR. A. M. WILSON IN LONDON LAST WEEK.

ing flowers on long stems well above the foliage. The huge, hideous stakes usually associated with a Dahlia-bed in early summer find no place with Collarettes, as the only support required is that afforded by their canes, which soon become completely covered by the graceful foliage, and the whole plant thus has additional merit in its artistic worth. The blossoms, too, have an increased value for floral decoration, as cut blooms last longer than those of any other Dahlia, while their long stalks and beautiful forms add to their charm and utility. From July right on till frost comes, a plentiful supply is available, and if cut freshly

NEW AND RARE PLANTS. THE BEST CLIMBING

AWARDS OF MERIT.

Odontoglossum Leviathan.—The name is suggestive of the giant proportions of this very handsome variety, whose petals are finely pointed, broad and overlapping at their bases, and, coloured dark chocolate to maroon, are irregularly reticulated with white and edged with the same colour.

Odontioda Zenobia leeana (*Odontoglossum percultum* × *Odontioda Charlesworthii*).—A small plant of this handsome bigeneric hybrid, having a two-flowered raceme, was shown. The colour is rich glossy maroon, with large, pure white lip. These were shown by W. R. Lee, Esq., Plumpton Hall, Heywood, Lancashire.

Lælio-Cattleya Nana (*L.-C. warnhamensis* × *L.-C. dominiana langleyensis*).—The sepals and petals are coloured orange scarlet, the frilled lip of rich ruby red tone suffused with velvety crimson. From Messrs. Flory and Black, Slough.

Auricula Edenside.—This distinct and pleasing variety belongs to the show fancy set. The individual flowers are large, well formed, though lacking slightly the ideal show standard of excellence. The colour is heliotrope, with lilac shading, which is in contrast to the large white centre. The variety has mealy foliage; is very vigorous, and bore a handsome truss of flowers. From Mr. James Douglas, Great Bookham.

Prunus Cerasus Chealii pendula.—A very handsome, free-flowering example of this drooping variety was shown, the pendulous branches of 3 feet or more long being studded with pink flowers. A variety of unusual merit and excellence, calculated to create new effects in the garden. From Messrs. J. Cheal and Sons, Crawley, Sussex.

Primula Reinii.—A Japanese species of dainty grace and charm which attracted considerably. Though not in the nature of a novelty, it is a plant of some rarity, and appeared at this meeting for the first time. It has petiolate, hairy leafage, which is deeply lobed when mature. The umbels rise well above the foliage, and are two to six flowered. The colour is rosy lilac, the notched flowers not unlike some of the *P. Sieboldii* set. Height, 4 inches to 6 inches. Exhibited by Mr. E. H. Jenkins, Surbiton.

Saxifraga Vandellii.—A superbly flowered example of this rare and difficult species was shown, which in a long experience we have never seen anything like so good. It is from the Southern Tyrol, and is distinct from all in its densely arranged dark green, spiny rosettes of leaves. Peduncles three to six flowered; flowers pure white, of large size. It loves calcareous soils. Shown by Messrs. R. Tucker and Son, Oxford.

Narcissus Chrysee.—A self yellow Ajax variety, rich and intense in colour, though small as trumpet Daffodils go to-day. The colour attracts, notwithstanding. From Messrs. Cartwright and Goodwin, Kidderminster.

All of the foregoing novelties were shown before the Royal Horticultural Society on the 13th inst., when the awards were made.

Some of the new Daffodils shown on this occasion, though they did not receive awards from the Narcissus and Tulip committee, were particularly interesting and good, and descriptions of several will be found in the Rev. J. Jacob's notes on page 199.

ANNUALS.

AN efficacious screen is oftentimes a most desirable thing in a garden, especially during the summer months, when many gardens are open to the public. Provided the subject receives consideration sufficiently early in the season, it is sometimes possible to make a temporary screen a floral attraction as well. That some annuals provide us with excellent material for such a purpose is amply illustrated by the Sweet Pea, which answers both purposes.

The climbing *Nasturtium* is also good, and gives plenty of flowers in a sunny position with its roots partly confined. This is easily carried out by placing a board or slates along each side of a 9-inch trench in which the plants are to be grown. A good support for the plants to climb upon is made by erecting some coarse-meshed wire-netting, or, if preferred, use the *Simplicitas* Netting, and then in either case thread it through with, or otherwise fasten securely to it, some dead Spruce or brushwood, and over this the *Nasturtium* will simply revel. Should the screen be required near the vegetable quarters or actually in them, the ornamental Bean may be more in keeping, and while making a very pretty pink and white feature, the additional use of a few gatherings of pods may be considered, although this can hardly be recommended for general practice, as the flowering must naturally suffer. Of course, the Runner Beans answer the same purpose, provided all the pods are removed as soon as formed. Personally, I prefer a few of each for the purpose.

Omitting the Runner Beans, the plants mentioned are equally useful for the covering of pergolas, trellis and such like. Other suitable climbers among annuals are *Cobæa scandens*, *Convolvulus major*, *C. Ipomœa*, *Eccremocarpus scaber*, *Humulus* (annual Hop), *Loasa aurantiaca*, and *Tropæolum canariense*. The best results are obtained by sowing the seeds of each variety in small pots under glass, and growing them on until all danger of sharp frosts has passed before planting them in their flowering or permanent positions.

When used as a covering for pergola or trellis, it is a mistake perhaps to entirely rely on the annuals to provide a good covering or show by themselves; but used in conjunction with established creepers and plants of perennial habit they certainly are capable of adding a little to the floral scheme. Care, however, should be taken that the annual does not flourish at the expense of the permanent subject by making excessive growth, and for this reason the annual Hop and the climbing *Nasturtium* need to be carefully watched when used to assist in covering any position.

Convolvulus Ipomœa rubro-cærulea delights in a sunny position, and is certainly a lovely blue creeper. *Eccremocarpus* has an orange and scarlet tone, and *Loasa* may also be said to have orange shades. Strictly, *Cobæa scandens*, with its purple, bell-shaped flowers, is a half-hardy perennial, but it answers well as a half-hardy annual if sown early in February. No doubt plants could be purchased during the next few weeks. As is well known, *Convolvulus major* (*Ipomœa purpurea*) may be procured in quite a

number of colours; and while *Tropæolum canariense* provides us with a yellow creeper, *Tropæolum lobbianum* Lilli Schmidt is a good scarlet.

Serlby Gardens, Yorks.

H. TURNER.

THE ROSE ANNUAL, 1915

ALTHOUGH rather late in appearing, this, the official organ of the National Rose Society, is an exceedingly interesting number, and will, we feel sure, be read with the greatest interest not only by the numerous members of the society, but also by many others who are interested in the Rose.

The contents are, as usual, of a very varied and practical nature. We would draw particular attention to the symposium on manuring Roses, to which Rose-experts living in various parts of the country, and growing Roses in all kinds of soil, contribute. The summary of these articles, prepared by Dr. A. H. Williams, is very useful indeed. Another interesting article is that dealing with "Municipal Rose Gardens," by Mr. W. Easlea. Rose gardens of this kind are being planted in the United States, but it is exceptional to find public Rose gardens in this country. The best we know—apart, of course, from those in the various botanical gardens—is that at Westcliff-on-Sea, two illustrations of which appear in the publication now under notice.

Mr. E. J. Holland contributes a very useful chapter on "The Prevention of Mildew on Roses Under Glass," and Mr. T. N. Cook of Boston, U.S.A., gives some interesting particulars about "Black Spot and Mildew." Rose species, which, of course, have been very much supplemented in recent years, are dealt with in a very practical manner by Mr. W. Dallimore, who draws attention to the best of the newer additions. We are also very pleased to notice the most lucid article by Mr. H. R. Darlington on "The Rugosa Roses." These Roses do not receive the attention they deserve from gardeners and amateurs generally. As will be seen by Mr. Darlington's list, there are a great many excellent Roses that belong to the Rugosa section that might be used much more extensively in our gardens than they are at present. Messrs. E. and M. Hockliffe put forward an excellent plea for the cultivation of Roses during war time, and one that we hope will not be ignored.

Those who appreciate cut Roses in the house—and we think everyone does—will derive much benefit from the very charming article by Mrs. H. R. Darlington on "How to Cut Roses." Until we read this, we must confess that we did not give very much thought to the right and wrong ways of cutting flowers. The Annual also includes a Rose analysis by Mr. Mawley, and the report of the Rose Conference held at the White City last year.

As usual, the volume is well illustrated, both with half-tone blocks and coloured plates. Two of the latter represent an arch and pergola respectively in Mr. Wettern's garden, and we wish the reproduction had been better so as to do justice to the very fine effects that he has obtained. The thanks of all rosarians are due to those who have given so much time and experience in its compilation. Copies can be obtained by non-members from the hon. secretaries, 25, Victoria Street, Westminster, London, S.W., price 2s. 6d. each, post free.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Bananas.—Very liberal treatment is required to fruit Bananas successfully. They must be planted out in a lofty structure giving them ample room to develop their large leaves. When the fruits are developing, liquid manure should be supplied frequently. A surface-dressing of rich farmyard manure will also be of valuable assistance. Plenty of heat and a moist atmosphere are necessary during the growing season, but the plants must be shaded from the direct rays of the sun. After fruiting, the old plants ought to be cut out, selecting the most promising suckers to take their places. These may be lifted with a good ball of soil and planted in a compost of loam, well-rotted manure and crushed bones. As the plants require abundance of water when in active growth, good drainage must be provided.

Cucumbers.—Fruiting plants will require constant attention to the stopping and regulating of growth. If this is neglected, they will quickly become exhausted. Cut the fruits when large enough and place the ends in water in a cool room. Preparations may now be made for planting a batch in cold frames. A hot-bed must be made on which to grow the plants, and plenty of litter placed round the frames will help to keep an equable temperature inside during spells of cold weather.

Plants Under Glass.

Freelias.—After flowering, the pots should be placed on a shelf in a cool house in order to ripen the bulbs. Keep the plants well supplied with water, supplementing this occasionally with liquid manure. When the bulbs are ripe, place the pots closely together in a cold frame to let them dry off.

Indian Azaleas.—As the plants pass out of flower, the old blooms must be removed. If repotting is necessary, it may be done now. They should then be placed in a warm, moist house to complete their growth.

Tuberous-Rooted Begonias.—Seedling Begonias must be transplanted when ready into boxes and kept moving in a warm, moist house. They will eventually require to be potted into 5-inch pots.

Gloriosa.—Where a suitable house is available, this is a most useful plant to grow, the flowers being very suitable and attractive for decorative purposes. When in active growth, the plants must be well supplied with stimulants. A few plants trained over the roof of the plant stove will supply plenty of flowers all through the summer months.

The Flower Garden.

Dahlias.—The old stools will now be throwing up young growth, and it will be an easy matter to divide them so that the most promising parts may be potted up. After potting, place them in cold frames, and keep them close for a few days till they have recovered from the check. They may then be inured to cooler conditions. The cuttings which were put in last month must be potted on when well rooted. Seedlings may be similarly treated.

Lobelia cardinalis.—If the plants have been well hardened off, those required for the herbaceous border may be put out. Those in boxes which are required for bedding out in June should be potted up singly into 4-inch pots and kept well supplied with water.

The Water Garden.—A great many subjects may now be planted in the water garden. If Nymphaeas are to be grown, they must be protected from swans. The following are suitable for associating with water: *Caltha palustris*, *Spiraeas*, *Ranunculus*, *Rumex*, *Polygonum amphibium*, *Stratiotes aloides*, *Myosotis palustris* *sempervirens*, *Butomus umbellatus*, *Funkias*, *Osmundas*, *Alisma*, *Sagittarias*, *Gunneras* and *Callas*.

The Hardy Fruit Garden.

Gooseberry Caterpillars.—These destructive pests must be watched for most assiduously, as they are capable of doing great damage in a few

days if left alone. Hand-picking is the most effective way to deal with them where time will allow. Powdered Hellebore is very effective, but owing to its poisonous nature it must be washed off the trees when its work is done. The powder should be dusted over the trees when the foliage is damp.

Mulching.—Any arrears of this work must be done without delay. It is often a difficult matter to obtain sufficient good manure for this purpose. I have used stable litter along the alleys with good effect.

The Kitchen Garden.

Potatoes.—No time ought to be lost now in planting the main crop of Potatoes. The sets should be planted in trenches about three inches deep, and the soil thoroughly worked while the operation of planting is going on. A distance of 30 inches ought to be allowed between the rows, allowing 12 inches between the sets.

Cabbages.—The season has not been favourable for the growth of most green vegetables, and while the earliest batch of Cabbages is now fit for use, the later plants are very backward. These will benefit by an application of artificial manure. Afterwards stir the soil between the plants with the hoe.

Runner Beans.—These may be sown outdoors about the end of the month or early in May, or be sown in 4-inch pots and planted out when the danger of frost is past.

Salads.—Sow Radishes in a sheltered situation every ten days or a fortnight. They require plenty of water during dry periods. Mustard and Cress must be sown according to requirements. A supply of Watercress may be obtained by planting cuttings in a frame under a north wall. It should be sprinkled with water every day.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Dwarf French Beans.—If the soil is in good order during the next few days, a start may be made outdoors by sowing a few rows of French Beans. As, however, continued rains after sowing would possibly cause the seeds to decay, only a limited quantity should be sown. For general productivity and reliability a good strain of Canadian Wonder is still the best to grow.

Seakale.—If root cuttings were placed in boxes as advised earlier, they will now be ready for putting out. Planting early will allow them a longer season to make good growth. A distance of 18 inches should be allowed between the lines.

Brussels Sprouts.—Plants which were raised early in the season and pricked out into cold frames three or four weeks ago ought now, after they have been properly hardened off, to be planted out where they are to grow. The lines should be drawn 3 feet apart, and a distance of 2 feet 6 inches allowed between the plants. After planting, a dusting of soot should be given to guard against slugs. Where wood-pigeons are troublesome, means must also be adopted to prevent their raids in the early morning, the time of day when they seem most active.

Leeks that were sown during January or February and have been hardened off are now ready for planting out. If extra fine specimens are wanted, they may be grown in trenches in a similar way to Celery; otherwise they can be planted in the open by making holes with a dibble and only allowing enough soil to fall in to cover the roots.

The Hardy Fruit Garden.

Wall Trees, such as Plums and Apricots, will be improved in shape if they receive a timely disbudding to regulate the growths. Young trees in particular can be assisted in this respect.

Mulching.—In very porous and light, sandy soils this is beneficial to established trees, also

to newly planted ones. Its benefit will be very apparent should any length of drought continue. It also encourages surface roots, which are always desirable for fruit trees, as additional food is then easily applied and quickly assimilated.

Fruit Under Glass.

Peaches and Nectarines.—While stoning is in progress in the early houses, no undue forcing must take place. If the temperature at night is maintained about 65°, this will be sufficient, allowing it to increase 10° or 15° during the day. If possible, try to avoid sudden fluctuations of temperature during this critical period.

Succession Houses.—As soon as it is certain the crop is set, a thinning should take place, as delay in this respect taxes the energy of the trees needlessly. Badly placed fruits and those on the under side of the wires must be removed first, leaving for preference the fruits which are well exposed to the sun and not in contact with wires or branches.

The Flower Garden.

Arrears of Work.—Any ground that is not already dug, and which is to be occupied later on by bedding plants, should be dealt with immediately, as it will be possible soon to make a start, planting out some of the more hardy subjects.

Hollyhocks.—These stately plants are not nearly so much grown as formerly, owing to their liability to collapse during the summer through being attacked by disease when in full flower. Raising young stock annually from very early sown seed is recommended; but owing to the shortness of the season in Northern districts, they only commence to flower when frost intervenes. Plants raised from seed sown indoors during January may now be put out where they are to flower.

Calceolarias should now be gradually hardened off in readiness for planting out next month. It is wise, however, to retain the covering materials at hand, as a sudden drop in the temperature below freezing point necessitates them being protected.

Early Flowering Chrysanthemums.—As these will soon have to be planted out, the lights must be kept off during all fine days and later removed altogether, so that the plants may become well hardened. If they are at present growing in pots, the plants could be stood outdoors altogether, with, of course, the protection of a wall or hedge. It would also be as well to have protecting material ready in case of frost.

Plants Under Glass.

Winter-Flowering Begonias.—The large and double-flowered sections are most useful additions, with their greater colour range, to the Gloire de Lorraine varieties, although they have not the same freedom of flowering. If plants were partly cut over early in March and have had a slight rest, they will by now be making young growths; these should be taken and propagated in bottom-heat. *Elatior*, *Eclipse*, *Lucy Clibran*, *Altrincham* *Pink* and *Bowdon Beauty* are among the best of this race of Begonias.

Arum Lilies.—The earliest batch will by this time be almost exhausted, and should be removed outdoors where there is the protection of a wall or hedge to screen them. Water must be withheld gradually until the foliage ripens, when it can cease altogether.

Evergreen Azaleas having passed out of flower and developing their young growths ought to be overhauled, and any that are in need of potting receive attention. The compost should be composed almost entirely of peat, with a little silver sand added. A very slightly increased size of pot will be best, as Azaleas are compact-rooting subjects. After potting, plunge the pots in ashes up to the rims and water with care. In bright weather the syringe should be used freely.

Coleus thyrsoides.—This useful winter-flowering plant can be increased by cuttings if given strong bottom-heat. After they are rooted and potted up, cooler conditions will suit their requirements.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET WILLIAMS DYING (*Susan*).—It is probable that the Sweet Williams have been attacked by the grub of a small two-winged fly similar to that which attacks Carnations; but you only send part of the plant. Possibly spraying the plants at intervals during the autumn with paraffin emulsion would tend to prevent the fly from laying its eggs.

PLANTS FOR BEDS (*Sussex*).—It is somewhat late now to be sowing seeds for making a good display during the coming summer, and, for some of the beds at least, we think you had better resort to young plants. For scarlet there is nothing to equal *Salvia* *Pride of Zurich*, and it is free and continuous in flowering. It is 2 feet high. *Salvia patens* is intense blue, though sparsely flowered, and should be planted thickly. *Nemophila insignis* is rich blue and free-flowering. Raise from seeds. It is not more than 6 inches high. *Verbena* *Lovely Blue* makes the finest blue bed we know, and *Verbena* *Miss Willmott*, if not true scarlet, is very bright and effective. Plants of these could be had from Messrs. Keynes, Williams and Co., Salisbury. For white, a good Ten-week Stock might be used, or *Antirrhinum*, by securing plants at once. Tuberous Begonias in white and scarlet could be started in boxes now and, planted in the first week of June, would give a succession of flowers till frost arrived.

PLANTS FOR WALL (*Mrs. C. B. A.*).—You have omitted two essentials in the case, viz., the height of the wall and its aspect; hence we cannot say what plants would be the most suitable for an old red brick wall. It would also be helpful to know something of the condition of the wall; that is to say, is the mortar good or in a state of partial decay? If good, some difficulty will be experienced in starting the plants, and much subsequent attention will be required. In certain instances seed-sowing is best, but that could only be done after preparing positions for the seeds. It is an easy matter to establish plants on a dry wall or one specially built to receive vegetable life, but quite a different thing to garnish a vertical wall correctly built. Is the wall "capped," and what facilities does it offer for planting on the top? The best general season for planting is the autumn. We do not know where near London you could see a wall planted with the largest selection. Those we know have been specially built, and would help you but little. If you will give us the above particulars, we will do our best to help you. We think, however, you would be well advised to consult a specialist on the spot.

VIOLETS UNSATISFACTORY (*E. M. H.*).—If your Violets were in good condition when placed in the frame in October, we are of opinion that your non-success is owing to want of sufficient air, and probably an excess of moisture at the roots. Violets in the winter are very particular in this respect, and unless great care is taken in the removal of all decaying leaves, the Violet disease, a fungus bearing the name of *Puccinia violæ*, is very apt to make its appearance. Violets in frames should

have plenty of air whenever possible, except during hard frost. Water must be sparingly applied at the same time; enough must be given to prevent the plants from suffering. This operation should be carried out on the morning of a bright, drying day, as by so doing any superfluous moisture will be dissipated before night. It is very essential that all decaying leaves be pinched off, while the soil between the plants may be occasionally stirred in order to prevent any stagnation. During sharp frosts the frame should be covered with mats. As soon as a thaw sets in, air must be given, even before the mats are removed, as this allows of the escape of superabundant moisture. Violets are benefited by being so situated that they are shaded from the sun during the very hottest part of the day in the summer; but during January, February and March they should have all the sunshine possible.

ROCK GARDEN.

DAMAGE IN ROCK GARDEN (*Harraby*).—Probably most of the damage of which you complain is being done by the millepedes and woodlice, and not by the ants at all. Ants rarely eat plants, though they feed on sweet fruits and on nectar, but are very apt to feed on insects. They do harm by making the soil about the roots too fine and in other ways, and the best way to deal with them will be to track them to their nests and pour boiling water upon them. The millepedes and woodlice may be captured by putting half Potatoes, slightly hollowed out near their haunts, examining the traps daily and killing the captures by dropping them into hot water or into water with a thin layer of paraffin on top.

THE GREENHOUSE.

NATIVE COUNTRY AND YEAR OF INTRODUCTION OF PRIMULA MALACOIDES (*P. E. K., Lockerbie*).—*Primula malacoides* was introduced by Messrs. Bees, Limited, and was by them brought prominently forward in 1908, on November 24 of which year it was given an award of merit by the Royal Horticultural Society. It may, of course, have been introduced a year or two earlier, as some time would be necessary to work up a stock before it was sent out. It is a native of the Yunnan district of China, where it is said to grow at an altitude of 9,000 feet.

REPOTTING VALLOTA PURPUREA (*E. M. H.*).—The best time to repot *Vallota purpurea* is directly the flowers are past, and, next, towards the end of the summer, just as the new leaves and flower-spikes are on the point of being pushed up. At the same time, it is not necessary to repot the plants every year; indeed, if the roots are in good condition, they will stand for two or three years without repotting and flower all the more freely. The *Vallota* does not require much root room; in fact, a mass of soil around the roots is very detrimental to its well-doing. A large single bulb may be accommodated in a pot 5 inches in diameter, and smaller ones in proportion. Whether the small bulbs are removed and potted by themselves is just a matter of choice, as if allowed to remain they will reach flowering size and in time form a clump; whereas, if taken off and potted by themselves, their rate of progress may be somewhat faster. In order to obviate frequent repotting, the soil for the *Vallota* should be of a good lasting character, say, two-thirds loam to one-third peat or leaf-mould, and a liberal sprinkling of silver sand. Unless the leaf-mould is well decayed and free from insects, peat will be better. If you had given us an idea of the condition your plants were in, we could have been more explicit in our reply.

KITCHEN GARDEN.

TOMATOES, MELONS AND CUCUMBERS (*J. H. S.*).—You will hardly get a full measure of success in attempting to grow any two of these together, as at certain seasons different treatment is required. The best division will be as follows: Reserve the warmer portion of the house to the Melons and Cucumbers, giving each a side to themselves, setting the plants on mounds of soil on the side stages and training them to wires fixed near the glass. Both crops revel in heat and moisture in the early stages. Later, at the period of fruit setting, and at ripening more particularly, the Melon prefers drier conditions than the Cucumber, which revels in heat and moisture at all times. For securing a good set, artificial pollination is essential in the case of the Melon. In the case of the Cucumber it is not desirable, the more shapely fruits being produced without it. The Tomato requires cooler as well as more airy conditions, and with a little warmth in the pipes the ventilators should never be closed completely. A close atmospheric condition for these soon favours mildew; hence must be avoided. You might certainly carpet the surface of the Rose-beds with Violas if you wish; it is frequently done, renewing the latter annually to admit of affording the soil of the Rose-beds proper cultivation.

MISCELLANEOUS.

SOWING MISTLETOE (*California*).—Mistletoe is sown by rubbing the berries into a crack in the bark of the tree—Apple being a good host—in May or thereabouts. The berries must be ripe when they are gathered, and they are not ripe until about May. If there are no cracks in the bark of the tree, a little piece may be lifted, preferably on a branch near the main stem, and the seeds rubbed into the crack of the bark, which is allowed to close again.

CATERPILLARS FOR NAMING (*J. Fraser*).—The caterpillars are, as we thought, those of the garden swift

moth. They are very fond of various fleshy-rooted plants, such as *Pæony*, and often attack bulbs, such as *Daffodils*. All that are turned up should be destroyed, and starlings and rooks eat considerable numbers of them. The moths themselves may be captured with a butterfly net when they are fitting over the flower-beds during early summer evenings. Some good might be done by putting traps of pieces of Carrot near their haunts.

MOSS ON LAWNS (*Pons*).—The past winter has been very conducive to the growth of moss, and lawns in most places have suffered. If large patches are covered with it, it would be best to rake them bare and sow grass seed in the places, but otherwise it would be well to spread sulphate of ammonia at the rate of half an ounce to the square yard (not more) on the grass. To obtain an even distribution, the sulphate of ammonia should either be dissolved and watered on at this rate, or be mixed with fine soil or sand and distributed. Any treatment, such as mulching with manure, which will encourage the growth of the grass, will discourage the growth of the moss. One of the advertised lawn sands would also destroy the moss if used according to the directions.

MANURE FOR PLANTS (*G. Robins*).—For all the plants mentioned, organic manure of some sort is advisable, but it may be supplemented in the case of Potatoes by a mixture of 5lb. of superphosphate, 2lb. of sulphate of ammonia, and 3lb. of wood-ashes at the rate of 3oz. to the yard of row; for ordinary vegetable crops like Cabbages, &c., a top-dressing of nitrate of soda up to 4lb. to the square rod, put on in small quantities at frequent intervals; for herbaceous plants, basic slag, 12lb. to 20lb. to the square rod, should be added when the border is dug. Basic slag may also be used for Roses when the border is dug or forked into the top spit in the winter, at the same rate, with a dressing of sulphate of ammonia, 2lb. to 3lb., and superphosphate, 8lb., in the spring. Fish guano, 10lb. to 20lb., or Peruvian Guano, 4lb. to 8lb., per square rod is also a good dressing for Roses where cow or pig manure is not available. Any of the proprietary manures advertised as general plant foods in our pages would prove useful for your crops, as they contain all the necessary elements of plant food.

NAMES OFF LANTS.—*Dry Garden*.—1, Probably *Abies grandis*; 2, *A. nordmanniana*; 3, *Picea excelsa*; 4, *P. sitchensis*; 5, *Cedrus Deodara*; 6, *Picea Morinda* (*smithiana*); 7 and 8, *Sequoia gigantea*.—*W. H. S.*—1, *Cryptomeria japonica*; 2, *C. elegans*; 3, *Thuja orientalis*; 4, *Cupressus lawsoniana*; 5, *Picea excelsa*; 6, *Coronilla glauca*.—*John Clymo*.—*Rehmannia angulata*.—*Cymry*.—*Pulmonaria officinalis*.

SOCIETIES.

HYACINTHS AND TULIPS FROM INDUSTRIAL SCHOOLS.

THE first of what it is to be hoped will be very many exhibitions of a like character was held at 117, Victoria Street, Westminster, on April 8 and 9, under the auspices of the Social Union for Workers Connected with Certified Schools. Considering that the regulations respecting the exhibition were only drawn up early in December last and then passed by the Reformatories Department of the Home Office, it was a most surprising and highly creditable display; in fact, some of the best-grown Hyacinths were fully equal to those shown by professional growers. Some three dozen schools sent in entries on this occasion, and, of these, exhibits were sent by seventeen boys and twelve girls from twenty-nine schools. Prizes to something like £10 are being offered annually by H.M. Chief Inspector of these schools. Boys and girls competed separately and individually for these prizes, and each school's collective exhibits were also recognised as a whole. In a few instances the exhibitors' names were not supplied by the entrants; hence it is not possible on this, the first occasion, to supply a complete list of the competitors.

Boys.—For the best pot of Hyacinths, three bulbs in a pot, the first prize went to a boy from the East London Industrial School, the variety being *Grande Maitre*, pale blue, with three finely developed spikes; second to D. Myles of the Stranraer School, N.B., with the same variety; and the third prize to N. Kaufman of the Hayes Industrial School. For Tulips, J. Auld, from the Stranraer School, was first with Cottage Maid, six bulbs in the pot; second, F. Friedlander of the Hayes School; third, a lad from the Hardwicke Reformatory. For a window-box with Tulips only, a very highly creditable exhibit was awarded the first prize; it came from an exhibitor in the East London School.

Girls.—The best Hyacinths—none better being seen in all the exhibition—came from two girls in the St. Monica's School, Croydon, the best being a fine pot with several spikes of a white variety, and the second best an almost equally good exhibit of a yellow variety. An exhibit from the Dovecot School by Ethel Parker was commended. Of Tulips, the best came from Florence Bond of the Dovecot School, and the second best from a girl at St. Elizabeth's School, Salisbury. Highly commended awards were given to the following schools: The Stranraer School, N.B.; the Essex Industrial School, Chelmsford; the Tradwell Training School, Chester; the Hayes Industrial School, Hayes, Middlesex; St. Monica's School, Croydon; the Hardwicke Reformatory; and the East London Industrial School, Lewisham.

NATIONAL ROSE SOCIETY.

THE spring show of the society was held in the Royal Horticultural Society's Hall on the 16th inst., and from many points of view must be regarded a success. This much is stated advisedly, bearing in mind the comparative sunless weather of the weeks preceding the show and the abnormal conditions prevailing. Regarded as a whole, the classes were not keenly contested; many, indeed, were not contested at all, a solitary exhibitor only appearing. Happily, this was not the case in the great group class, which brought three of the more important exhibitors. Some of the cut-flower classes were also well contested; the flowers excellent.

NURSERYMEN'S CLASSES.

For a group of Roses in pots arranged on a space not exceeding 250 square feet, three competitors entered, the premier award being given to an admirably arranged group from Messrs. Hobbies, Limited, Dereham. Fronted by a bordering of Baby Elegance, Ellen Poulsen and Jessie, blush, rose, and crimson Polyantha sorts respectively, the exhibit was rich in weeping, standard and pillar sorts, and aglow with the finer Hybrid Teas and others. One of the more striking was the white-flowered Lemon Queen, a pillar sort of much excellence; while White Dorothy Perkins, Hiawatha and Pink Pearl (single) were all charming. Among dwarf pot plants, Old Gold, Sunburst, Geoffrey Henslow (very dark), Mrs. Andrew Carnegie, Snow Queen and the renowned Mme. Edouard Herriot were noted. The weeping kinds towered well above the rest, and afforded a fine display. Mr. Charles Turner, Slough, was second, having a border of Mrs. W. Cutbush, Orleans Rose, Ellen Poulsen and Jessie. Within this boundary such good things as Mme. Edouard Herriot, La Tosca, Richmond, Lady Hillingdon and Mme. Auguste Nonin, a pretty pink-flowered wichuriana sort, which was in great profusion, were seen among others. Messrs. Paul and Son, Cheshunt, were third in this important class, employing many well-grown, well-flowered standards in their group, though standard Roses hardly make for good effect. Of this particular style of growth were Mme. Edouard Herriot, Juliet, George Dickson (very dark), Louise C. Breslau (a fine cream-coloured sort), Arthur Goodwin and Mme. J. Dupuy, every plant affording evidence of cultural excellence. Among dwarf sorts were Mrs. F. W. Vanderbilt (salmon rose) and Viscount Carlow (cream pink). Silver Moon, a pure white single pillar sort, was very beautiful.

For a group of cut and pot Roses on a space not exceeding 100 feet, Mr. George Prince, Oxford, who arranged a half-circular group, was the only exhibitor, receiving the first prize for a nice lot. His best examples—Old Gold, Snow Queen, Mme. Edouard Herriot (very rich and beautiful in colour) and Mrs. Herbert Stevens (a superb white)—were all shown in big stands, and gave a fine display. Tea Rambler, Shower of Gold, Moplight, Mme. A. Nonin (pink-flowered wichuriana) and Hiawatha were other good ones in the group.

For a group of pot and cut Roses on a staging space 20 feet by 3 feet, Messrs. B. R. Cant and Sons, Old Rose Gardens, Colchester, were the only exhibitors, securing the first prize for an admirable lot. Employing imposing stands and vases for the most part, the firm displayed such as Antoine Rivoire, Mme. Melanie Soupert, Lady Pirrie, Silver Moon (a fine single white), Autumn Tints, Hugh Dickson, Hon. Mrs. R. C. Grosvenor and Mme. Edouard Herriot to advantage.

For six pillar Roses in pots, Messrs. Hobbies, Limited, Dereham, were alone, having Baby Elegance (blush), Excelsa, Pemberton's White Rambler (very good), American Pillar, Arcadia (crimson) and Lady Blanche (a pretty double white). The same exhibitors were alone in the class for six weeping standards, and were again awarded first prize, showing similar varieties to those named above.

In the class for fifty Polyantha Roses in pots, to be staged on the floor, two exhibitors came forward, the first prize being given to Mr. C. Turner, Slough; second, Messrs. Hobbies, Limited, Dereham. In the former, Ellen Poulsen, Jessie, Mrs. Cutbush, Orleans and Katherine Zeimet (white) were shown. In the latter, Amory Forceau (blush, double) and Annie Muller (rose, semi-double) were the more conspicuous.

In the cut bloom class, thirty-six blooms in not fewer than twenty-four varieties, there were three competitors, Messrs. B. R. Cant, Old Rose Gardens, Colchester, taking the lead, having a superb flower of Mrs. Edward Mawley (which gained the silver medal) and excellent examples of Lyon, Mme. Melanie Soupert, Souvenir de Pierre Notting (fine yellow), Captain Cant, Dean Hole, Richmond, Hon. Mrs. R. C. Grosvenor (blush), Hugh Dickson, Antoine Rivoire and William Shean. Second, Messrs. G. and W. H. Burch, Peterborough, who had very good Yvonne Vacherot

(blush), Edward Mawley (red), W. Shean, Prince de Bulgarie and Frau Karl Druschki. Messrs. F. Cant and Co. were third with less weighty blooms, though The Bride, Mme. Charles Lutaud, Avoca, Juliet and Mrs. Fred Straker were nice examples.

For eighteen cut blooms, not fewer than twelve varieties, there were again three contestants, Messrs. A. Dickson and Sons, Newtownards, being in the place of honour with a high-class lot of flowers. Sunburst, Souvenir de E. Guillard, St. Helena, Lady Plymouth, Mrs. Foley Hobbs, Lady Greenall (of a lovely saffron orange) and Lady Barham (coral pink) were among the best. Second, Mr. Elisha J. Hicks, Twyford, who had excellent blooms of White Killarney, Hugh Dickson (dark red), Edward Mawley, Mabel Drew (cream), Mrs. Charles Reed (blush) and Marian Grace Wells (rose). Third, Mr. G. Prince, Oxford, whose White Maman Cocot, White Killarney and Frau Karl Druschki were all good.

For six pots of new Roses, Messrs. Paul and Son, Cheshunt, were the only exhibitors. The best varieties were Edgar M. Burnett (a small La France), Leonie Lambert (blush pink) and Dr. G. Kruger (reddish), the

for Mrs. Charles Reed, Mme. Edouard Herriot and Mrs. George Roupell, the last of cream and light orange, and very charming.

For a collection of Roses cut or in pots, the last-named exhibitor was again alone, being awarded first prize for a group which included Princess M. Mertchersky (peach colour), Juliet, Liberty, British Queen, Prince de Bulgarie and Mrs. T. Webber, all in good form.

For six distinct new Roses, one stem of each, two competitors appeared, Messrs. A. Dickson, Newtownards, being awarded first for Souvenir de E. Guillard, Killarney Brilliant, Mrs. Forde, Primrose and others; second, Mr. E. J. Hicks.

AMATEURS' CLASSES.

CUT BLOOMS IN EXHIBITION BOXES.

For twelve blooms, not fewer than six varieties, Mr. E. J. Holland, Sutton, was alone, and was awarded first prize, showing Melanie Soupert, Cleopatra, Cynthia Forde, Dean Hole, St. Helena and Mme. Jules Gravereaux.

The above-named exhibitor was first for six blooms of any one variety, showing a glorious set of William Shean, a lovely pink variety and splendid grower, but lacking fragrance. This variety also gained the silver medal. Second, Dr. C. Lamplough, Alverstoke, who staged Mme. Jules Gravereaux.

Mr. E. J. Holland was the only exhibitor in the basket class for one basket of one variety, staging excellent Melanie Soupert, and for one basket, any number of varieties, gaining the first prize in each.

LADIES' SECTION.

For a vase of cut Roses lightly arranged, there were three competitors. Mrs. F. A. Tisdall, Woodford Green, was first; second, Mrs. Courtney Page, Ridgway, Enfield, both having excellent Kaiserin Augusta Victoria. Mrs. Chaffey Giddins, Barnet, was third with My Maryland.

For a decoration of cut Roses for a dinner-table, six competitors entered, most of the arrangements being good. First, Mrs. Courtney Page, Ridgway, Enfield, who set up an imposing lot of Ophelia (cream and pale pink) with light trails of Asparagus Fern. We thought the main central vase too formal-looking. Second, Mrs. Brown, Brokes Lodge, Reigate, who had a superb lot of Richmond with the lightest touches of Jessie and Asparagus Fern; third, Mrs. F. A. Tisdall, Woodford Green, whose arrangement was the most delightful of all. At judging-time this lot was insufficiently open; at 2 p.m. it was glorious. Two exhibitors used the famous Mme. Edouard Herriot, but the flowers were somewhat coarse-looking and lacking colour.

NON-COMPETITIVE CLASSES.

Messrs. Piper, Bayswater and Barnes, were the only exhibitors here, and arranged a highly artistic lot of flowers in baskets, vases and on stands. Liberty, Mme. Abel Chatenay, Mme. Edouard Herriot, Kaiserin Augusta Victoria, Sunburst, Lady Hillingdon, White Queen, Richmond and Molly Sharman Crawford were some of the more beautiful in a glorious lot of flowers.

NEW VARIETIES.

Two new varieties received the high award of the society's gold medal. The most interesting of these was

Hoosier Beauty.—A glorious scarlet crimson bloom of great fullness and substance of petal, with long, stout stems. The shape is semi-conical, and the petals are slightly reflexed, as we see them in Miss Cynthia Forde. Its outstanding feature, however, was the delicious perfume. This was exceptionally pronounced. We understand this superb novelty was raised in America, and is a seedling of that grand maroon crimson Rose Chateau de Clos Vougeot. Shown by Messrs. G. Beckwith and Son. The other gold medal variety was named

Queen of the Belgians.—This is a large, single pink flower, with a prominent central disc of yellow stamens. The petals are broad and shell-like, and the flowers are produced singly on long, slender stems. The raiser and exhibitor, Mr. E. J. Hicks, claims that it is perpetual flowering. It should prove very useful for table decoration.

A new variety that received a certificate of merit was named

Mary Greet.—This came from Messrs. Alex. Dickson and Sons, Newtownards. It is a large, full flower of conical shape, borne on very long and stout stems. It reminds us somewhat of Pernet-Ducher's Entente Cordiale when at its best.

BEST BLOOMS.

The best blooms in the show, for which the society's silver medal is given, were: In the nurserymen's section, a magnificent flower of Mrs. Edward Mawley, shown by Messrs. B. R. Cant and Sons; in the amateurs' section, Mr. E. J. Holland secured the honour with a really wonderful flower of William Shean.

THE NEW ROSE HOOSIER BEAUTY. THIS RECEIVED A GOLD MEDAL LAST WEEK. (See accompanying text).

latter having but one flower. The first prize was awarded.

The class for twelve Maréchal Niel blooms brought but one exhibitor, Mr. A. T. Goodwin, Rose Holm, Maidstone, who staging a superb dozen, took the first prize. The blooms were handsome in size and finely coloured.

For twelve blooms of any variety other than Maréchal Niel, three competitors entered, Messrs. A. Dickson and Sons, Newtownards, being first with J. Campbell Hall, a handsome pink and blush; second, Messrs. G. and W. H. Burch, who staged Mrs. Foley Hobbs (deep crimson); third, Mr. E. J. Hicks, who had excellent examples of Mrs. George Norwood (of rosy pink hue).

For six distinct varieties in vases, not more than five stems of each, only two competitors entered, Mr. E. J. Hicks being first with Princess Mary (a glorious single crimson), Mrs. Charles Reed, Mme. Edouard Herriot, Harry Kirk and Marquise de Hautpoul (rosy peach); second, Messrs. G. and W. H. Burch, Peterborough.

For three baskets of cut Roses, distinct, Mr. E. J. Hicks was the only exhibitor, being awarded first prize

THE GARDEN.

No. 2267.—VOL. LXXIX.

MAY 1, 1915.

NOTES OF THE WEEK.

A Choice Dwarf Rhododendron.—Some excellent plants of the dainty little blue-flowered *Rhododendron intricatum* are now flowering well at Kew, both in the rock garden and among the Heath collection near King William's Temple. The bushes are scarcely more than a foot high, the small, lilac blue flowers being freely produced in clusters of four or more. A native of Western China, this dwarf shrub is likely to prove one of the most useful of the many introductions that have reached us from that country during the last decade.

A Charming Narcissus for the Rock Garden.—Among the *Narcissi* that are suitable for the rock garden, *N. triandrus pulchellus* occupies a foremost place. The graceful flowers are produced three or four on each scape; the perianth is primrose and the cup white. It prefers a little shade in gritty soil, and a well-drained, sheltered position, when it will last in bloom for some time. With a carpet of *Viola gracilis* the effect is most attractive.

A Pleasing Spring Flower-Bed.—Whatever position *Anemone fulgens* is planted in is made conspicuous, providing the *Anemone* succeeds at all. A bed filled with it, intermixed with double *Arabis*, makes a very effective contrast, and one that can be seen from a good distance. The *Arabis* was planted in the autumn, when pieces were dibbled into the bed, and at the present time it is one of the most conspicuous beds in the garden. When it has ceased flowering, the *Arabis* will be pulled up and the bed then filled with its summer occupants.

A New and Rare Flowering Shrub. The illustration on this page represents a flowering spray of a new and as yet rare hardy shrub or small tree from China. This is named *Styrax hemsleyana*, and in appearance resembles *S. Obassia*, itself a rather rare shrub. The flowers illustrated are pure white, the racemes being about six inches long. In its native country this *Styrax* makes a small tree about twenty feet high. It should be planted, when quite small, in a mixture of peat and leaf-soil, combined with the ordinary soil of the garden. It is a very beautiful shrub, and will doubtless be extensively grown when plants are more easily available.

A Charming Spring Effect.—We were very interested in a simple scheme of white and

blue that we saw in a Southern garden a few days ago. Some sturdy bushes of the white-flowered *Magnolia stellata* had been planted near the front of a large shrub border, and beneath these the ground was lightly carpeted with the bulbous plant *Muscari Heavenly Blue*. The effect, particularly when kissed by the spring sunshine, was exceptionally pleasing, and should be noted for reference when the planting season, *i.e.*, October or November, comes round. Both shrubs and bulbs will thrive in well-drained soil of a moderately light character.

Treatment of Bouvardias.—Plants which have finished flowering may be cut well back and placed in gentle heat, and, when the young shoots appear, the plants may be shaken out of the old soil and repotted in a compost of turfy loam and leaf-soil. Place them in a temperature of 60° until the pots are well filled with roots, after which a lower temperature will suit them better. *Bouvardias* may easily be increased by cuttings, which should be taken as near the old wood as possible. Fine sifted loam and leaf-soil, with plenty of rough sand, will suit them well. Plunge the pots in gentle bottom-heat in a close pit.

Crown Imperials.—These are among the boldest and showiest of bulbous flowering plants, with their hanging cups of yellow, gold, red, or orange. For growing in the shrubbery in large groups they have few equals at this season, as they give a bold relief to their surroundings. To avoid a blank space afterwards, *Anemone japonica* should be grown with them. There are variegated forms, both golden and silver, and, happily, they belong to the red-flowered section, a fact which renders them the more conspicuous. The golden-leaved form is now one of the most ornamental in the hardy plant garden, and those who do not possess it should procure it early in the ensuing autumn.

A Pink and Blue Combination.—A rather daring combination of colours may be seen at Kew just now. Close by the Victoria Gate a large bed of the double-flowered Peach, *Prunus persica carnea plena*, is in full flower, the shrubs attaining a height of from 10 feet to 15 feet. The colour of the blossoms is a deep shade of pink, and attracts the attention of numerous

visitors. The ground beneath is carpeted with the Apennine Windflower, *Anemone apennina*, the blossoms of which are a pleasing shade of sky blue. The combination of pink and blue is good, though whether it would be so pleasing were the Peach flowers nearer the earth, and consequently closer to the blue, is doubtful. Lilac-coloured and pale pink flowers we know always make a charming association. For instance, nothing is more pleasing than *Nepeta Mussinii* planted with pink China Roses, but one would not care to carry the depth of either colour too far.

A FLOWERING SPRAY OF *STYRAX HEMSLEYANA*, A NEW AND RARE SHRUB FROM CHINA.

Thinning Herbaceous Plants.—Now that such plants as *Phloxes*, *Michaelmas Daisies* and *Heleniums* have shoots several inches high, we would remind readers of the desirability of removing the weakest of these. Three, four or five good sturdy growths to a plant are ample, and the clearing away of the remainder at this early stage will be amply repaid at flowering-time, inasmuch as the blossoms will be larger, of better colour and greater substance. Of course, where the plants are lifted annually or biennially, and only the strongest outside portions replanted, there is little necessity for any thinning at the present time.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Magnolia stellata.—Despite the experience of Magnolias as detailed by your correspondent "G. G." on page 183, he does not appear to have made the acquaintance of *Magnolia stellata*. A specimen of this species that formed a large tree as stated in the note in question would be something to write about. I note, however, that it is referred to in the past tense, so conclude it no longer exists. This is a pity, for we shall probably never see its like again. Besides this, a tree of *Magnolia grandiflora* like an Oak would be a decided novelty.—A SCEPTIC.

Berberis pinnata.—The tall Barberry about which Mr. Comfort writes on page 194, issue April 24, is not *B. Aquifolium* (Mahonia), but *B. pinnata*, closely akin to the other and not distinguishable from that species in a young state. Mr. Bean, in his recent admirable book on "Trees and Shrubs" says that some authorities reckon these to be varieties of a single species; but the habit of the two is very different in well-grown specimens. *B. Aquifolium* never becomes anything but a dense spreading shrub some 4 feet high, whereas *B. pinnata* does not spread by suckers, but rises with strong arborescent stems to a height of from 12 feet to 16 feet. It is a beautiful thing at the present season.—HERBERT MAXWELL, *Monreith*.

The Clivia as a Window Plant.—What a fine, noble-looking window plant the *Clivia* makes! Yet how seldom is it seen so grown. In a house not far from where I write are two large, healthy-looking specimens just throwing up their flower-spikes. I see them every day, and they appear to inhabit the same windows the whole year round, thus proving how amenable they are to that kind of treatment and position. The showy flowers—shades of orange red—are borne on stout stems and generally stand well out of the foliage, which is strap-shaped and somewhat of a thick, leathery nature. In a cut state the flowers keep good in cool surroundings for practically a fortnight. A suitable growing compost is loam, old decayed manure and sand. It is a good practice to keep *Clivias* on the dry side for a little while after flowering; it rests them. Another name for them is *Imantophyllums*.—C. T., *Highgate*.

The Cultivation of *Lupinus polyphyllus*.—My experiences in attempting to raise *Lupinus polyphyllus* from seed seem to me to be of enough general interest to relate to readers of THE GARDEN. For three summers I sowed seeds, which germinated well, but the seedlings soon became yellow and died after forming a few small leaves. On discussing the matter with a friend, it was suggested that perhaps the necessary bacteroid was wanting in the soil. Acting on this suggestion, I obtained some soil from a garden in which *L. polyphyllus* would grow. With this I top-dressed the seed-boxes, and the yellow, sickly seedlings soon began to grow strongly. When they were large enough, I pricked them out into a nursery bed and top-dressed them again with the foreign soil. By the autumn, when the young plants were dug up to be transplanted in their permanent quarters, they had made roots several feet long, with the typical nodules. No foreign soil was used in the permanent quarters, and the plants are now throwing up strong young shoots, so I am hoping this year to obtain flowers from them. An inter-

esting point in connection with other species of *Lupinus* is that no difficulty was experienced in growing *L. arboreus* from seed in the soil which would not grow *L. polyphyllus*. This fact seems to suggest that different species of bacteria are needed by *L. polyphyllus* and *L. arboreus* respectively.—GARDEN STEWARD.

Two Showy New Barberries.—Among the many new Barberries received from China during late years, there are several which promise to become very useful shrubs, for they have a pleasing habit and bear bright-coloured fruits freely late in the year. Two of these species which possess special attractions are *Berberis stapfiana* and *B. subcaulialata*. They bear some resemblance to *B. Wilsonæ*, the first of the new Chinese species to force its merits upon garden lovers. *B. stapfiana* is a vigorous shrub with gracefully arching branches, the young bark of which is red. At the base of each bud are three strong, sharp, needle-like spines, the larger ones being about three-quarters of an inch long. The tiny leaves are one-third to two-thirds of an inch long and one-twelfth to one-eighth of an inch wide, green above and glaucous below. Yellow flowers are borne in June in small clusters from each bud on the previous year's wood, and they are followed by bright red fruits, which ripen in October. The second species, *B. subcaulialata*, is also of graceful outline. It is distinguished from the former by its less ferocious spines, by its leaves having a rounded instead of a pointed apex, and by its fruits being red and cream in colour. In both cases the fruits are rather late in ripening, and are at their best during November and December. Both kinds succeed in ordinary garden soil, are apparently perfectly hardy, and are easily grown from seeds, which should be sown as soon as they are ripe.—W. D.

War on Wasps.—Allow me a little of your valuable space to remind readers of the vast importance of waging war on wasps this year. All foodstuffs will be dear, and I do not think any people can afford to let their fruit crops be spoilt through lack of a little attention and trouble. Moreover, it is not only one's self that one must think of, for all your readers may not have orchards and fruit trees in their possession; one must think of other people a little. Of course, the war on wasps when once begun should be continued, if necessary, all the summer, and any nests found later on should be destroyed by inserting a rag soaked in turpentine at each entrance hole and covering it up with turf; but a method which will effectually prevent there being anything like a number of nests is for every reader to make an effort to trap the queen wasps. The best way to do this is to hang up bottles with wide necks, or jars, filled from a third to half of their depth with strong-smelling liquids, such as beer, stout, or beer and sugar. These bottles should be hung up on trees, evergreens, and in any place which may be suitable for the queen wasps to hover about, and should not be placed so that they are covered from sight by foliage. Of course, this method is very unsightly, and often involves considerable labour and trouble (not to speak of injuring the gardener's reputation as a temperance man if he must buy beer or stout at the shops!); but it is surely well worth it. Wasps do such a terrible lot of damage to fruit that severe war is really necessary against them. These receptacles may remain for catching ordinary wasps in the summer, and should be refilled periodically.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Quality in Vegetables versus Size.—"A. La T.," on page 183, issue April 17, touches the spot—a very sore one—between the cook and the gardener. The "battle of the Broad Bean" in particular I have fought annually for forty years. Most of us will agree with "A. La T." that the Broad Bean is only fit for table when quite young and small. The gardener hates to gather it before it has grown coarse and large and is only fit for pigs. Carrots, too, can scarcely be too small and tender for a table delicacy. But the gardener seems to think we are donkeys, and offers us large, inferior exhibition ones, often not worth cooking. The same trouble constantly occurs in the case of Beetroot, Onions (for boiling), Vegetable Marrows, Cabbage and, in fact, most vegetables. I combat the difficulty as far as I can by carefully avoiding all exhibition kinds when ordering seeds. I suggest that it would be very interesting and instructive, and an eye-opener to the (often wilfully) blind seedsmen and gardeners, if at the vegetable shows a committee of good housekeepers and cooks were appointed as judges.—ANNE AMATEUR.

—This subject having caught my eye on page 183 of your valuable paper, I naturally read carefully "A. La T.'s" remarks, and, on second thoughts, I was inclined to think she could hardly be serious. Fancy one having to eat Broad Beans as large as kidneys, Brussels Sprouts as large as Walnuts, Salsify, one stick of which is enough for a helping; and Cauliflower which no woman could tackle alone! Really, Mr. Editor, this would be enough to make one ill. Surely, one who can afford to use Broad Beans when not larger than Marrowfat Peas should be in a position to be able to make her own selection from a reliable seedsmen's catalogue rather than trust to a collection. "A. La T." has a perfect right to grow what varieties she chooses, and to pick or waste them at her own discretion; but what about the toiling masses and the thousands of our population, many of them in a fairly good position, but with large families, who are only too thankful to our seedsmen and others for the improved varieties in the majority of kinds of vegetables? Our present-day judges and best exhibitors never favour mere size; quality being the first and most important consideration. I have just taken up one of our leading seedsmen's catalogues with the object of proving whether "A. La T.'s" remarks that the smaller and more refined-looking vegetables are now only mentioned in small print, and seldom, if ever, sent out in the guinea or other collections, are correct. Now, I find that the large majority of kinds of vegetables are fairly representative, both the large and smaller growing kinds, and there are many cases where the latter are strongly recommended in large print. I will name a few: Peas, French Beans, Beetroot, Brussels Sprouts, Cabbage, Savoy, Cauliflowers, Carrots, Celery, Cucumbers, Lettuce, Vegetable Marrows, Onions, Radishes, Tomatoes, Turnips and Potatoes. Surely enough for "A. La T." to practise with for a year.—EDWIN BECKETT.

—"A. La T." seems in a very great deal of trouble about vegetables. I do not know whether it is a man or woman who is writing, but the first part gives one the impression that your correspondent is a member of the gentler sex. We know on a great many tables small vegetables are more appreciated than large ones. One only needs experience and a glance at all the leading catalogues to find plenty of varieties that are small.

The great difficulty seems to many to grow things good enough to be called anything but small. If "A. La T." had to supply a household of always twenty persons, and often more, with enough vegetables for thirteen hot meals a week, large vegetables would not be such a grievance; and when one gets used to the splendid varieties that grow so large, it would take a long time to go back to small things that are often strong and stringy. My experience is this: that excepting a very few things that are really needed small, vegetables have made very rapid strides in quality during the last twenty years.—G. ANDREWS.

Undesirable Plants for the Rock Garden.—

Like Mr. E. T. Ellis, I had no intention of writing another letter on this subject, but as he asks me if I have grown "Arabis albidula fl.-pl. as an alpine for a few years together," I should like to say that the only use I have for it is as a vegetable doormat. It is evident Mr. Ellis and I have different ideas on alpine gardens. Who would grow Vincas, &c., mentioned by him as alpine, to the certain destruction of choicer plants? I do not remember having seen Mr. Ellis' favourites growing in the alpine gardens at Wisley, Kew or Friar Park. *A fortiori*, no true lover of alpine would attempt them in a small garden, even under a "slight drip." Has Mr. Ellis yet tried another "alpine," by name *Campanula rapunculoides*? If not, let him plant it without delay. Drip or no drip, I think it will overtake *Cerastium* or double *Arabis* before long, even with the start they have. Why will people grow these out-of-bound customers when they can get more interesting plants like *Androsaces*, *Saxifragas*, &c.?—A.

How to Grow Anemone fulgens.—

Some two or three years since I think there was some correspondence in your columns as to how to grow this plant. May I relate my experience of it? In a desultory way I have grown a plant or two of it, and, noticing they flowered well every spring, I indulged in a hundred last autumn. I planted them in very sandy soil with a little leaf-soil, protected from the north and east by some tall Hollies and Rhododendrons. Early in February they began to throw up their foliage, and about March 1st a few were in bloom. They have flowered profusely through March and into the last week of April, each plant producing about a dozen flowers. There is nothing I know of which is so brilliant on a sunny day in spring as *Anemone fulgens*, and it is especially valuable as it flowers in a month when our gardens are none too gay. Besides, it is cheap, and I find it easy. I do not trouble to lift it.—ALPINIST.

Rock Gardening and its Votaries.—I always read with pleasure "Anne Amateur's" contributions to THE GARDEN—they are so fresh and humorous; but I feel I must protest against

her note in the issue for April 17, which I do not think is justified by what has appeared in your columns. It is much to be regretted for her own sake that with an abundance of sandstone, the possession of which I envy, she does not start the cultivation of rock plants. But I think if she pursues her theory a little further, to eschew exotics, her garden will not be better than—what I admit is very beautiful—the hedge banks of a deep country lane. Her pathetic reminiscence of the Parsley Fern is, I cannot help thinking, a reflection on the lady who looked after it, and it brought to mind those hackneyed lines, "Oh! ever thus from childhood's hour." But I should very much

NEW ROSE QUEEN OF THE BELGIANS. THIS HAS PINK FLOWERS AND RECEIVED A GOLD MEDAL IN LONDON ON THE 16TH ULT.

like to know the further history of her "hedge of sorts." I read her invitation for suggestions and advice and how it was responded to, and I much wondered whether she had adopted the planting of so many exotics in her hedge, which when it grows up against her neighbour's fence will prove very interesting and toothsome to her neighbour's cow, horse or donkey.—E. B.

FORTHCOMING EVENT.

May 11.—Royal Horticultural Society's Exhibition and Meeting, 1 p.m. to 6 p.m. Lecture at 3 p.m. Royal Horticultural Hall, Vincent Square, Westminster.

SEASONABLE NOTES ON AURICULAS.

WITH the arrival of May the Auriculas will be getting past their best, the early flowering varieties being already out of bloom. The beginner should bear in mind that the stems must not be removed, as is the case in the majority of plants, the flowers being pinched off at the top of the truss, and the stem or flower-stalk allowed to gradually dry up, when it can be removed later on.

Repotting.—The most important work for May is repotting the plants, and I always endeavour to complete this task before the end of the month. Those that have passed the flowering stage are first taken in hand. The compost consists of good fibrous loam three parts, and leaf-mould one part, to which may be added a moderate sprinkling of silver sand or crushed oyster-shell. A 6-inch potful to every bushel of the soil will suffice. In some districts the loam is poor in quality, and the deficiency can be made up by adding a little decayed manure, such as may be secured from an old hot-bed. I have occasionally used a little bone-meal, and with very good results; but the amateur should not be too generous with it. As a general guide I advise not more than a 4-inch potful to each bushel of the rooting medium.

How the Repotting is Done.

I must state first of all that large pots are not necessary, and many can often trace their failure to overpotting. For full-grown examples, pots of the long thumb pattern measuring 4 inches in diameter will be large enough, with perhaps a slightly larger pot for an exceptionally strong plant. Smaller specimens should be placed in receptacles just large enough to take the roots. Ample drainage must be provided, and to this end each pot should have one-third of its depth filled with broken potsherds. Both crocks and pots ought to be clean, and if

they have been previously used for Auriculas, a good scrubbing will be necessary to remove all traces of the woolly aphid.

Having prepared the compost and the pots, one can then proceed to overhaul the plants. All the old drainage should be removed and the greater part of the soil, but I never adopt the method of shaking all the soil from the roots. Sufficient must, however, be taken away so that the bottom of the stem can be examined. If the end is decayed, it should be cut back to living tissue and then rubbed over with a little lime or powdered charcoal. In some instances the stem will be in an excellent state of preservation, and in consequence will be too long to allow the foliage to be brought near the

soil. When I have such examples to deal with, I never hesitate to shorten the stem to bring about the desired result; but the beginner should remember that no harm will accrue if the base of the stem rests upon the drainage. In all probability the roots will be covered with woolly aphis, and before disturbing the ball of soil beyond removing the drainage, I usually go over the roots with Tobacco powder or apply a little methylated spirit with a camel-hair brush. Press the soil fairly firm and leave sufficient space for watering, and when the operation is completed the leaves will be near the soil, the plants thus presenting a smart appearance.

Subsequent Treatment.—Arrange the plants in their growing quarters and give a thorough watering. For the present keep them shaded from all strong sunlight, and only give enough water to keep the foliage from drooping. In the

the Rose pillars harmonise with the general scheme of colour, we do not see why they should be omitted. There is a tendency, however, in a few gardens to overdo them. That and the use of unsuitable varieties are dangers to be guarded against.

THE SCOTCH ROSES IN BEDS.

THERE has been within recent years a perceptible increase in the attention devoted to the Scotch Roses, forms of *Rosa spinosissima*, which were at one time exceedingly popular. The greater number of the eighty or more varieties cultivated in the thirties of the nineteenth century are now lost—at least so far as regards their names—but there are many of these to be

for association with others. In themselves the small flowers of the Scotch Roses are extremely pretty. Few of them are of stiff formation, and many are of the most elegant contour and delightful in every way, though too small to please those who worship size in flowers.

The beds may either be, as has been said, composed of one variety alone—and for this purpose one of the double yellows makes a beautiful group—or they may be composed of varieties of different colours, either mixed or in blocks of each variety. One advantage offered by these Roses is that they are generally offered on their own roots, as they produce suckers freely and also strike readily from cuttings. Their habit of making suckers is, indeed one of the obstacles to their more general employment in gardens. In beds they should be carefully attended to and the suckers either removed, or, better still, periodical replanting performed.

The Scotch Roses are not difficult to satisfy in the way of soil. They will grow and flower in poor soil, but they well repay more generous treatment, and the culture adopted for other Roses, which need not now be detailed here, is eminently adapted to give larger and more lasting flowers. The plants are easily kept to the height required by annual pruning, while they never fail to give an abundance of bloom.

The old Double Yellow is one of the most plentiful, and it is a pleasure to observe it so freely grown in many cottage gardens, where it flowers most profusely year after year. The Double White is also excellent, though not so common as the yellow. One called Staffa is also double, but its flowers are of what we know as "French white." Lismore is another good double variety, the flowers being nearly pure white, but just tinged with blush sufficiently to take away the purity without reducing the beauty of the flower. There is a good double pink one named Townsend, but there are other pink varieties, one of the best of these passing, generally, simply as the Scotch Double Pink. Falkland, an old variety, has pale rose flowers, passing off nearly white; it is a capital flower. The old double rose variety called Grahamstown has had a long career and is a favourite with growers of the Scotch

Roses. Berwick, another very old variety, is semi-double and is pretty with its deep rose flowers, which are touched with white along the edges. William III., a dwarf variety, makes a charming bed by itself, and is very useful for edging other varieties. It has small, double crimson flowers and is only a few inches high. Stanwell Perpetual has semi-double, light blush flowers and has the merit of being a good autumnal Scotch Rose, in addition to flowering well early in the season. Globe has rose flowers; Lady Hamilton has buff white, rose-shaded buds. It opens semi-double and is then rosy blush. Dundee is double and rose with a white reverse. Other double or semi-double varieties might be mentioned, but any will give satisfaction. Some of the singles appeal to many. Of these the Single White; ochroleuca, golden yellow; and the Single Yellow may be referred to by name.

Dumfries.

S. ARNOTT.

A BORDER OF MIXED FLOWERS WITH ROSE PILLAR IN THE BACKGROUND.

next article I shall give a few more details in this direction.

T. W. B.

ROSE PILLARS IN FLOWER BORDERS.

SOME years ago, when a few gardeners more daring than their fellows introduced pillars of Roses to the herbaceous or mixed flower border, they were subjected to criticism that was not always exactly courteous. That they were more far-seeing than their critics gave them credit for has been proved subsequently, and in most well-ordered gardens these pillar Roses are now given a place in the flower borders. In these days of gardening for effect, nine borders out of ten are filled with many kinds of plants, some shrubby, some of annual duration only, and others that are only half-hardy, but planted there to fill the hiatus that would otherwise occur at some time during the summer or autumn. Therefore, so long as

met with in gardens where all record of the names has disappeared. At present it is difficult to secure more than a dozen named Scotch Roses from any individual nursery. There are enough, however, to make pretty hedges in the garden, while these Roses form one of the daintiest of all Rose beds, either one variety alone or several intermingled. Their flowers are not too lasting, it is true, and the display of bloom is shorter than that given by some other classes of the Queen of Flowers, but they are exceedingly pretty while in bloom, and, even when the flowers are over, the foliage is frequently beautifully tinted. A bed of Scotch Roses on the grass gives wonderfully charming effects.

One good feature of these Roses is that whatever varieties are planted together, there is no jarring colour effect. The hues seem to agree in every way, and there is not among them the hardness of colouring which renders some Roses unsuitable

DAFFODIL NOTES.

BY THE REV. JOSEPH JACOB.

The London Show (Continued).—I am afraid there were a good many grumblings about the accommodation provided for two of the three blue ribbon classes of the exhibition in the dark eastern annexe. If in trying to carry out the old maxim of when in Rome doing as Rome does I, too, allowed a slight growl to escape my lips, I humbly apologise to the Royal Horticultural Society of England, and I hereby ask all fellow-grumblers to do the same, more especially in the light of future events. We were wrong, very wrong. It was their solicitous care that had prompted them with wonderful prescience (or was it upon a secret hint from the War Office?) to guard the choicest flowers of the show from all possibility of being seen by any prying Taubes or Zeppelins, for it is quite obvious that such beautiful examples of "Kultur" would act upon German nerves like a red rag does on a bull. One hopes that equal thoughtfulness will be shown next year if the war is still with us. Alas! it may be.

Competitive Classes.—The number of entries was not as many as usual, but there were some excellent blooms to be found. I consider the twelve blooms staged by Mr. P. D. Williams in the silver-gilt cup class for seedlings raised by the exhibitor were as good a lot as I have ever seen. Quality and variety were its outstanding merits. The grand bloom of Whelp was a magnificent example of good culture, while an exquisite white trumpet, quite in the style of the still unbeaten White Knight; a fine shapely yellow one featuring Alchemist, which was illustrated in THE GARDEN last week; and a round, white-petalled, large, flat, red-eyed bloom, a little like a smooth Cossack, were superb.

I was very glad indeed to see Messrs. Barr and Sons' exhibit in the Engleheart Cup class for twelve blooms, old or new, and I congratulate the firm most heartily on their winning it. I happened to be one of the judges, and it was a very great surprise on going back, when the cards of identification were turned, to see who had carried off the first prize. Now that the ice is broken, I hope our other large trade firms will enter the lists. Fides, a large, symmetrical, pale bicolor Ajax in this twelve, came very near to being, in my opinion, the best bloom in the hall. Yet on the morning of the second day I was bombarded with "Where is Lord Kitchener?" I thought the War Minister must have come to inspect the measures taken for the safety of the flowers, and, incidentally, that of London; but I soon found that it was only the *Times* that had been doing a little judging "on its own," and had stated in the morning's issue that Lord Kitchener

Daffodil was the flower of all others to see, as being the newest and the best. It might have spotted a worse one. The seedling classes were very interesting. It was decidedly a "trumpet" show. They were present in force, here, there and everywhere, as they say. Buncombe's Bonamy, Miss Warren's fine yellows in Class 34, and Wilson's pale bicolors in Class 2 were all of a very high order. Then, Batson's 489 broke new ground. Its corona was so very small in diameter, being $1\frac{1}{4}$ inches long and a bare three-quarters of an inch wide. Mr. P. D. Williams' yellow trumpet 510 did the same. Its perianth was a most delicate

its dictums overboard whenever they do not agree with it, the question must undoubtedly be raised whether it is worth while having such a book at all. I am going to ask a question on this in committee when we next meet.

It was very pleasing to find Mr. Watts among us in khaki as a second lieutenant in the Army Service Corps (Welsh Division Territorials); but it was a pity he attempted so much, as none of his flowers was named, and in many cases the arrangement in the vases showed haste in setting them up. Captain Kitchin was also present in uniform, but did not exhibit anything. In the second amateur section Major Churcher of Woodcote, Alverstoke, gained six firsts. I thought there were fewer really poor flowers staged this year than ever before. The division of the amateur classes seems to work well, inasmuch as it attains its object, which is the giving as many as possible a chance of winning prizes. In Section III. we had Major Churcher, Canon Fowler and Miss Warren as the top dogs, while Mr. G. Stocks was a good runner-up. In Section II. Mrs. Gage-Hogg, Mr. Morton and the Rev. T. Buncombe divided the prizes between them.

Awards of Merit.—Two awards were given, to Chryse and Bath's Flame respectively, while the shapely Leedsii Venus only just missed one. Chryse is a very deep yellow Jonquil hybrid of good size, but it struck me as being too rough to ever make a first-rate show bloom; its colour carried it through. The corona is widely expanded, and has a distinct scalloped edge. Dimensions: D, $3\frac{1}{2}$; S, $1\frac{3}{8} \times \frac{7}{8}$; C, $1\frac{1}{4} \times 1\frac{1}{2}$. Bath's Flame gives one the impression of a glorified and magnified Barrii conspicuous with rather a looser general look, owing to the length and narrowness of the segments. The award in this case was given for garden purposes; hence a note should be made of its long stem of at least 20 inches.

Some Striking New Varieties. In all cases in which I have taken the measurements they are given, and also the name of the raiser.

Alchemist.—A clean-cut yellow trumpet (1A) of good substance and texture, with pointed segments well imbricated towards their base and a long, bold corona. Raised by Mr. A. M. Wilson. A rich deep yellow self.

Bonamy, raised by the Rev. T. Buncombe, is a somewhat pale yellow self of excellent proportions and rounded appearance. The segments turn up very slightly at their ends towards the trumpet, giving the whole flower a distinct style of its own. I am afraid in the hurry of getting its photograph taken I omitted to take its measurements, and the same is the case with Alchemist. This last was the larger flower. It would probably be about

NARCISSUS BONAMY, A BEAUTIFUL NEW PALE YELLOW TRUMPET VARIETY. (See text)

lemon and far removed from white, but the judges accounted it a bicolor. When I asked one of them why, I was reminded that the definition of it was "white or whitish." The judges were probably right, as I see, princeps in the classified list is pigeon-holed as a bicolor. The same judges in a class or two further on disqualified Cræsus in the division for yellow-perianthed incomparabilis or large-cupped Daffodils, because they said its perianth was not yellow. I cannot understand this, for it is put down in the classified list as 2A, and if judges are to be allowed to throw

4½ inches in diameter, while Bonamy would be about 3½ inches.

Paris, raised by Bath, Limited, is one of what I call the squat trumpet type. Not that I like the word, but I cannot think of a better. As will be seen from the measurements, the corona is on the short side, though not quite so much as might be inferred, were it not known that it has a wide flange. It is a deep yellow self. D, 4½; S, 1½ × 1¼; C, 1¾ × 2½.

Joffre (Bath, Limited) stood out well as a clean-cut Ajax of a pretty pale shade of yellow. It is a pure self. D, 4½; S, 1½ × 1¼; C, 1¾ × 1¾.

The Don (Bath, Limited) is certainly one of the best varieties that Mr. Leak has raised and, naturally, he is very proud of it. It is a pale bicolor trumpet, the perianth imbricated and the corona boldly flanged. It is the result of a cross between Weardale Perfection and Mme. de Graaff, the first of the two being the seed-bearer. Dimensions of bloom: D, 4½; S, 1½ × 1¼; C, 1¾ × 2. It will be of interest to many to know one of Mr. Leak's experiences with trumpet crosses. He has kindly permitted me to raise the veil, for he, like myself, feels himself to be a bit of a missionary about seedling raising. In many cases he has found that what he considered his best crosses are often very disappointing; while, when he has used such a rough diamond as Mme. Plomp as the seed-bearer, the results have been good.

Dorcas (A. M. Wilson) is a beautiful Jonquil hybrid of perfect form. It is distinguished by having a corona of a rather deeper shade than the perianth. Segments beautifully flat and imbricated. D, 3½; S, 1½ × ¾; C, 1 × ¾.

Ixion (Barr) is a striking giant incomparabilis or a very large, big-cupped Daffodil. The flower has a slightly drooping poise. The perianth is flat and imbricated, set at right angles to the corona, which is a bright orange red; coloured almost to the very base. D, 4½; S, 1¾ × 1¾; C, 1 × 1¾.

Gadfly (J. C. Williams).—This is also a somewhat drooping flower with an ivory white reflexing perianth and a telling eye of orange, with a broad band of dull rose. D, 3; S, 1½ × 1; C, 1.

P. D. Williams' No. 99.—A very refined white trumpet Daffodil which reminded me very much of White Knight. The perianth was solid, smooth and clean cut. One of the best flowers in the show. D, 3½; S, 1¾ × 1¼; C, 1¾ × 1.

Livonia (Mrs. R. O. Backhouse), a pretty Giant Leedsii with undulating perianth and a buff expanding cup. It stood out as very distinct in Mr. Wilson's twelve. D, 3½; S, 1½ × 1¼; C, 1 × 1½.

Jason.—A pale bicolor trumpet of Cactus form. D, 4; S, 1¾ × 1¼; C, 1¾ × 1½.

Carpathian (Engleheart).—A flower that may make a good garden plant. Very much after Glory of Leiden. D, 4½; S, 1¾ × 1¼; C, 1¾ × 2.

THE SEA PINK OR THRIFT.

ALTHOUGH *Armeria vulgaris*, or *maritima*, is a native plant of our sandy coasts, it is well worthy of inclusion among other plants in gardens, particularly those situated inland, where it would not be found in a wild state. Its neat tufts of green, grass-like foliage make an excellent edging to pathways, especially where the soil is sandy and where many other plants would fail. One has pleasant recollections of rural cottage gardens where it is so used, and where, from June onwards until well into August, its globular flower-heads give a rare display of rose pink colour. As a rock garden plant, where plenty of space is

A BEAUTIFUL GROUPING OF THE SEA PINK IN THE ROCK GARDEN AT FRIAR PARK.

available, and where it can be massed in quantity, this humble plant, or one of its varieties, will create a cascade of green and pink such as few other plants are capable of. Evidence of this is shown in the accompanying illustration, from a photograph taken in Sir Frank Crisp's garden at Friar Park, Henley-on-Thames. The white-flowered variety, named *A. vulgaris alba*, is a charming plant, and the same may be said of *A. v. lauchiana*, with extra deep pink flowers and a more tufted habit than the type. Another variety, known as *Crimson Gem*, is also worthy of a place, its blossoms being a good shade of bright crimson.

G. D. S.

THE MORaine AS A FEATURE OF THE SMALL ROCK GARDEN.

THE moraine is the latest craze among alpinists; it is the latest phase of rock gardening, and one of the most fascinating. It is also a subject on which lately a very great deal has been written. However, I do not think it is an exhausted ground yet, and I propose to treat it in a way which I think is simpler and less expensive than any I have heard of. It is no doubt an advantage to have such things as underground water, but to some the very mention of perforated pipes and water supply is a final and insuperable obstacle. I myself was in a position rather like this, being landed with over a ton of granite chips and a plot in my rock garden about three yards by two yards to turn into a moraine. I decided that the additional expense which would be involved in introducing water was too great, and so proceeded to build my moraine without it, and I may truly say that I have never regretted my decision.

It is for rock gardeners in the same position as this that these words are intended. The labour for a small moraine is not at all heavy, and very interesting. The cost varies according to the stone used and the distance it has to be carted. Living as I do on the Surrey-Sussex boundary, granite and limestone both have to be brought a considerable distance. For various reasons I decided that I could get granite cheaper and more easily than limestone. When all was paid, including carting the chips four miles from the station, they cost me 18s. As all the making of the moraine was done by myself, the labour cost me nil.

The Best Stone.—If a choice of stone is possible, the blue "Craven" limestone is usually considered ideal; almost any limestone is good. Sandstone

should be used with caution, as some forms are too soft and crumbly when in chips. Granite is satisfactory in almost every respect, except that it is not quite as porous as might be desired, and so does not withstand drought quite so well. However, it is very pleasing to look at, as the colour is good and shows off the plants to the best advantage. Broken brick makes an excellent substitute for stone, and can be mixed in equal parts with the chips in the lower layers. The surface, if possible, should be pure stone for 2 inches or 3 inches.

The Soil to be mixed with these chips I formed of loam and leaf-mould in equal parts, and a little

peat for some plants. If there is no grit among the chips, a little sharp sand should be added. I mixed this with the chips in the proportion of one to seven or ten.

How the Moraine was Made.—The ground being prepared, I spread 4 inches or 6 inches of broken bricks over it, and beat these down to make them firm and to prevent the chips washing away through them. The moraine mixture was then laid over them to a depth of 18 inches or 2 feet, and made more or less level. As it was my object to make this as natural as possible, I carried the chips back between two small cliffs, from which the moraine now spreads in quite a realistic way. To make it easier to tend the plants, some flat pieces of stone were sunk here and there to step on. To keep the chips from washing down on to other parts of the garden, the moraine was irregularly edged with fairly large rocks. It is a great help to see some well-made moraine before embarking on the construction of one, and I think that no one will do amiss to visit the rock garden of the Royal Horticultural Society at Wisley in Surrey and see the moraine there.

Suitable Plants.—I planted in this moraine chiefly difficult things and those that especially dislike excessive moisture. Among the *Androsaces* I have *Chamaejasme*, *Chumbyi*, *glacialis*, *Hausmannii*, *primuloides*, *sarmentosa*, *sempervivoides* and *villosa*. The larger ones, of the *sarmentosa* group, are romping, and the smaller ones, with the exception of the difficult *glacialis*, are strong and happy. They all like lime except *glacialis*. I am not quite sure whether *sarmentosa* is best in the moraine. It is always so glorious in a good chink. Of *Campanulas* there are *Allionii*, *cenisia*, G. F. Wilson, *pseudoraineri*, *pulla*, and there used to be *Zoysii*, but I have now lost it. All the others are flourishing. *Allionii* and *cenisia* I keep right away from lime in pure granite. The Pinks (*Dianthus*) are represented by *glacialis* and *Freynii*. Both are dwarf and very slow spreading, but well worth some trouble, as the stemless pink flowers, which nearly cover the plant in the case of *Freynii*, are very beautiful. They are almost impossible out of the moraine.

Gentiana verna is an excellent moraine plant, but requires more moisture than the average. This, however, can be supplied from above. Associated with *Primula farinosa* it is one of the most lovely sights of the marshy spots in the Alps, where I collected them both. I do not think we can do better than follow Nature's example and plant them together. The smallest *Geum*, *reptans*, is also very happy among the stone chips. Its large, bright yellow flowers are very pretty above the dark green leaves. *Edraianthus pumilio*, a plant closely allied to the *Campanulas*, which bears a profusion of beautiful purple blue bells above the thin grass-like leaves, is an ideal moraine plant. Of the *Primulas*, *carniolica* is not well suited; in fact, it was only through a stray label that it was ever planted

there. *Farinosa* does well and retains its dwarfest form. It survives drought very well in the moraine. *Tyrolensis* is a wee treasure, but constantly attacked by slugs. It is very like *Allionii*.

Perhaps most of my moraine plants are *Saxifragas*, and certainly they are at home. *Borisii* (yellow), *diapensioides* (white), *Grisbachii* (red), *lilacina* (pale lilac), *porophylla* (red), *scardica* (white) and *Strybnyi* (red) have all been planted, and, except for *Borisii*, with signal success. I think *Borisii* would prefer a sunny pocket with leaf-mould and grit. *Diapensioides* must have a great deal of lime. *Grisbachii* is a splendid plant, and, as I write, five red flower-stalks are gradually growing longer and longer out of one plant. It should be well surrounded with fairly large pieces of stone. *Lilacina* is a tiny cushion like a lichen, with large, pale lilac blooms, borne singly. It is a treasure, and grows to perfection in the grey chips. This also is just finishing a goodly flowering

ANEMONE NEMOROSA BOSNIACA.

THE typical Wood Anemone (*A. nemorosa*) is known to all, and no woodland wilding, probably, is more appreciated, as in the early springtime it carpets the earth with its white blossoms. It is interesting and instructive at such times to mark the varied places in which it makes its home—now in the driest of places, where later the Bracken will tower well overhead; anon in places cool and moist, often quite wet—yet apparently happy in both, if varying in stature by reason of its environment. It is usually, however, in moist places and in cool, deep loams that it shows its fuller strength and luxuriance, and at such times it may reach to 9 inches or more high. Object-lessons of such moment should never be ignored by the gardener, since it is out

ANEMONE NEMOROSA BOSNIACA AS A ROCK GARDEN PLANT.

season. *Porophylla* is a small red-flowered species of comparatively easy culture and very pretty. *Scardica* grows well and flowers, but not very freely.

Lastly comes the lovely *Strybnyi*, a curious plant with drooping flower-stems bearing red flowers almost obscured by the hirsute calyx of the same colour. Two *Soldanellas* also thrive in an odd corner. Last autumn I added *Androsaces pubescens* and *helvetica*, *Dianthus alpinus* and *cal-alpinus*, *Lewisia*, *Cotyledon* and *Saxifraga retusa*, but so far I know very little about them.

The only ones I protect with glass are the woolly *Androsaces*, *Gentiana verna* and *Campanula cenisia*. I hope the experience recorded above will induce some other readers to take up this fascinating and not over expensive hobby, suitable for large or small gardens. G. PHILIPSON-STOW.

Blackdown House, Fernhurst, Sussex.

of their teaching value that gardens, often enough, may be beautified beyond the limits of orthodox or rule-of-thumb methods. The fine blue Wood Anemone (*A. robinsoniana*) I have grown to a foot high with its toes constantly in water; but the fact has never precluded my planting it in light, well-drained soils, in which a plentiful supply of cow-manure compensated to some extent for the absence of moisture and cooling effects the other situation naturally afforded. True, a lesser stature—I do not think a diminished beauty—resulted; but on the principle that “a small loaf is better than no bread,” it gave much satisfaction. Of the white-flowered Wood Anemones there are several forms, single and double: *alba flore pleno*, *bracteata flore pleno*, *rosea*, *rubra* and the subject of the present note, so admirably portrayed in the accompanying illustration. It is shown on a raised bank in the rock garden at

Kew, far away from water or its cooling effects, yet beautiful withal. In its rounded form it is the most comely of the white-flowered sorts, pinkish in the bud state, the colour showing a suffusion through the otherwise white petals. It is a great beauty, meriting universal cultivation. E. H. JENKINS.

CONCERNING GARDEN SEATS.

ALTHOUGH the present weather does not conjure up any pleasant picture of sitting in the garden, we are well on the road to summer, and even the cold wind does not make us forget that warmer days are coming. There is little wisdom in deferring thoughts of garden seats until we are ready to use them, for they take some time to make. It is not so many years ago that the last word in garden seat design was rustic, and the main endeavour was to secure enough stout, contorted branches of which to build the arms and backs of seats. It must be admitted, however, that these seats were often very uncomfortable, and certainly they do not accord well with the formal sort of gardening which is now almost universal.

With a more conscious sense of design in the outlines of the garden itself, the deliberate use of natural forms in rustic woodwork has rightly gone out of fashion. We approach the question rather with the intent of producing furniture

seen in our illustration on page 213, which serves, moreover, to adorn another moral. One of the principal uses of garden furniture is to emphasise the lines of the garden itself. Seats and tables should be placed so that they form pleasant focussing points in a vista, or help to outline (as in the latter illustration) the shape of the spot where they are placed. No doubt it is ideal from the practical point of view that they should be of some hard wood like oak, which grows silvery grey under stress of weather, or teak, which is even more durable. Nevertheless, the well-seasoned deal, of a sort that does not tend to split on exposure to rain and sun, is good enough if carefully and regularly painted. Green is a doubtful colour, as it is likely to quarrel with the varied natural greens which are near it. On the whole, white is the safest, though it is apt to look rather staring during the seasons when there is no brilliant colour in the flower garden to relieve it. It is well to provide a paved space for such heavy wooden furniture as is not likely to be moved about, for gravel is not ideally comfortable for the feet, and the disadvantages of grass are obvious. L. W.

PRIMULAS FOR THE WOODLAND.

It is remarkable that whereas Daffodils, Bluebells, Crocuses and even Michaelmas Daisies are freely naturalised in the woodland, yet the wide range of hardy Primulas, so naturally adapted to the woodland, have to a very great extent been overlooked. Even the common Primrose, native of our woods and dells, has been sadly neglected

achieved, while the bulbous plants naturalised under trees and in the wild garden are the admiration of all who see them. Happily, there are many gardens in which the Primrose may be freely grown, and for beautifying a damp, rather low-lying piece of open woodland there is nothing to equal the hardy Primulas, including the Primrose. The value of these hardy flowers in the woodland was forcibly brought to mind last year when visiting the extensive gardens at Clandon Park, Surrey. Here were to be seen little copses in which *Primula denticulata* and its improved and immensely popular form *cashmeriana*, with rich violet purple blooms, were flowering to perfection. Other Primulas were naturalised, such, for instance, as *Polyanthuses*, *Primula japonica*, and even the dainty *P. rosea*. *Primulas farinosa* and *Sieboldii* had been planted extensively, while the newer species, *cockburniana*, *bulleyana* and *Veitchii*, were being tried in similar situations. The beautiful undulated woodland of this Surrey garden, provides ideal surroundings for Primulas. H. C.

SOME INSECT TREE PESTS.

THE numerous insect diseases which attack trees deserve careful consideration from gardeners and foresters, for by timely attention to an affected tree it is sometimes possible to check an epidemic. A familiar disease among Spruce is known as the Pineapple gall disease. The common Spruce (*Picea excelsa*) and the

Sitka Spruce (*P. sitchensis*) are subject to attacks, particularly when the trees are not growing under the most favourable conditions. Diseased trees are readily recognised by the swollen places noticeable on the shoots. On young shoots the galls are green, but on old branches they are brown and dead. These galls appear on one side of the branch and resemble a small cone with needles attached. They are caused by a minute insect (*Chermes abietis*), which punctures the bark when it is very soft and tender. The insect goes through several changes in form during its life cycle, and should be attacked during spring. If a tree is not badly infested, the galls may be picked off and burnt, but, in any case, much good can be done by spraying every ten days during May and June with an emulsion

formed by incorporating six pints of paraffin with 1½ lb. of soft soap and adding the mixture to thirty-six gallons of soft water. The paraffin and soap should be well mixed in one and a-half gallons of boiling water until the soap is dissolved. By this means a creamy emulsion is formed which can be mixed with the water.

The same insect attacks *Abies nobilis*, and forms ring-like galls on the under sides of the branches. This, however, is not the insect

A SELECTION OF PLAIN WHITE GARDEN SEATS.

which is a translation in stouter and simpler shapes of the forms used within the home. Corners of the garden now approximate more to the idea of outdoor rooms, and are to be furnished accordingly. The illustration above shows such a treatment in a garden at Wittersham, Kent, where the three long benches, two armchairs and a table show a pleasant formality of treatment in keeping with their surroundings. On much the same lines are the two curved benches

as a subject for the woodland garden, for it is seldom seen except when planted by Nature. One reason that may account for this is found in the fact that Primroses require a much heavier soil than would suit the above-mentioned bulbous plants, and when planted on a light soil Primroses deteriorate after a year or two. At Kew, where the soil is of a light, open nature, frequent attempts have been made to naturalise the Primrose, but a really good display of bloom has never been

which causes the gouty swellings so frequent about the growing points of stems and branches of that tree. Frequent applications of the foregoing mixture are beneficial. It not infrequently happens that trees growing on hot, dry soils, or under other unfavourable conditions, are attacked by scale insects. Among conifers, species of Cupressus, Thuya and Juniper are very liable to attack; while among deciduous trees, Willow, Ash and Pyrus are often victims. The conifers may be treated in spring as recommended for the Spruce aphid, while deciduous trees may be given in addition a winter wash of a stronger character, which will help to cleanse the bark of all kinds of impurities. This wash may be composed of 2lb. of caustic soda (98 per cent.), 1lb. of soft soap, five pints of paraffin and ten gallons of water. The soap and paraffin should be mixed with a gallon of boiling water and the soda with the remaining water, afterwards mixing all together and using as a spray. The mixture must be applied on a calm day, as it is biting, and will cause the skin to peel off the user's hands and face if he allows the spray to blow back over him. D.

SEASONABLE NOTES ON VEGETABLES.

THE months of April and May are among the busiest of the whole year in the kitchen garden. There are so many details in sowing seed, planting, regulating the crops and generally tending to the various items of culture that procrastination has its due reward. So many crops can be spoilt in such a short period by neglect; for instance, the thinning of Beet, Carrots and Parsnips, or the neglect in supporting a row of Peas just at the moment when the tendrils are searching for some support to cling to.

Onions.—No time should be lost in finally planting out the Onions raised under glass. Where a quick and luxuriant growth has to be made, the soil must be well enriched. A sprinkling of Thomson's Vine Manure at planting-time assists growth. Lift the plants carefully with a trowel or handfork, with a ball of soil attached to the roots. Do not plant deeper than before, and so keep the bulb on the surface. Should the weather be dry, sprinkle the plants overhead for a few days.

Peas.—Continue to sow Marrowfat varieties thinly in deeply dug, well-worked soil. Remove the shelter of evergreen boughs from those planted out, giving them all available light and encouragement to grow away freely. Earth up and stake successional rows. Pinch the haulm of those that

are at the top of the supports, removing all lateral growth to concentrate the whole energy of the plant into the swelling of the pods.

Runner Beans should be sown in boxes now for the earliest crop. Place in gentle heat until the seedlings are well above the soil; then remove them to a cold frame, and plant out towards the end of the month in well-prepared soil in double lines 10 inches apart, with the same distance between the plants, protecting the seedlings

plants to suffer for want of water. Plants carrying crops of fruit under glass should have all surplus growth removed and be fed with stimulants of a weak nature.

Turnips.—Continue to make sowings of Snowball, Milan and All the Year Round in well-watered drills should the weather be dry at the time, so as to hasten the germination of the seed and induce the plants to grow away quickly out of the way of the fly.

SIMPLE BOLD SEATS OF CURVED DESIGN PROPERLY PLACED IN THE GARDEN.

at first from cold winds with green boughs or boards stood on edge on the north or east side of the row.

French Beans sown in small pots early in April will now be ready to plant out in frames, both heated and cool, which will give a succession of pods. Cover the cold frames with mats, as a late frost would check the growth. A rich compost is all in favour of French Beans; they grow away more quickly, produce larger leaves, and with these more succulent pods, which is the all-important point in this vegetable. Where they grow slowly, the pods are hard and stringy; therefore every encouragement should be given to induce rapid growth. Frequent syringings when closing the frames, with plenty of sun, help considerably in this direction.

Beetroot.—The main crop should now be sown in drills 14 inches apart, covering the seed with some fine compost.

Tomatoes.—Plants intended for outside against walls and in the open should be shifted into larger pots as desired, and be grown steadily on in a cool house or frame, confining the growth to one stem, removing all side shoots, and never allowing the

Marrows in Frames, and now in the fruiting stage, should have special attention. Ventilate freely and fertilise the b'ooms to ensure a good "set." Water regularly, as much of the dropping of the fruit is attributable to dryness. Sow more seed for outdoor batches.

Winter Greens.—Seeds of Kales, Savoy and Sprouting Broccoli sown during the next week or ten days will provide plants that should come in for use during March and April of next year. Thin sowing and early transp'anting are essential to success.

Leeks should be planted out in well-prepared trenches after the manner of Celery as fast as they are ready, lifting carefully with a good ball of soil attached to the roots, which will prevent a check being given the plants. Protect the plants from cold winds with evergreen boughs. Keep the hoe moving among growing crops like spring-sown Onions, Carrots, Parsnips and Lettuce.

Mulch Peas at once if there is a prospect of drought. Fork over the soil between rows of Potatoes if in any way in a sodden condition at planting-time.

Swanmore, Hants.

E. MOLYNEUX

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Peaches and Nectarines in Pots.—The trees on which the fruits are approaching the ripening stage must be thoroughly exposed to the light, and in order that the sun's rays may reach all the fruits, some of the foliage should be removed or tied aside. The roots may receive a top-dressing of rich farmyard manure, and an abundance of water must be afforded till the fruits actually commence to ripen, at which stage water should not be given to excess.

Early Permanent Trees.—When the fruits have finished stoning, an effort ought to be made to expose them fully to the light. This may be done by propping them up with short pieces of lath. Keep all lateral growth removed and cut back fruitless wood to the basal growth. Mulch the roots with rich manure, and liberally supply them with stimulants. When the fruits commence to ripen, it may be necessary to afford slight protection from bright sun, as some varieties are very susceptible to scorching.

Figs.—To get fruits of the finest quality, they must be well exposed to light and air; therefore all surplus growth must be removed. When the first crop has been gathered, give the trees a thorough washing with the hose-pipe. If a second crop is desired, the fruits should be thinned liberally, and where the growth is too dense, the knife ought to be freely used. Later trees must have copious supplies of stimulants. Give plenty of air during favourable weather, and leave the top ventilators open slightly all through the night.

Plants Under Glass.

Chrysanthemums.—A batch of cuttings may be struck for flowering in small pots. Preference should be given to the single varieties for this purpose. Providing they have been properly hardened off, some of the most forward plants may now be placed in a sheltered position outdoors. The large-flowered kinds must be securely staked, and as a further precaution against rough winds, hurdles should be placed in suitable positions to screen them.

Arum Lilies.—These may now be moved to a sheltered position outdoors. Reduce the supply of water to the roots till the foliage dies down; then turn the plants on their sides for a period of rest. In the month of August they may be repotted.

Humea elegans.—These plants will resent any attempt to hasten them into flowering; therefore keep them moving steadily and shade during the hottest part of the day.

Rose Fortune's Yellow.—We have daily for the past two months been cutting dozens of this beautiful Rose. When the trees have flowered, the flowering wood is cut back to the base. The borders are top-dressed with fresh materials, and plenty of stimulants are afforded the trees during the summer months. The growths will require to be liberally thinned out several times during the season.

Carnations.—Malmaisons are now developing their flower-spikes, and will need more stimulants than hitherto. Clay's Fertilizer alternated with soot-water will promote strength and colour to the flowers. Remove all the side buds from the spikes and keep them neatly staked.

The Flower Garden.

Hardy Ferns.—Most of the plants are now in active growth, and it will be necessary to go over them and remove old dying fronds and weeds. Many species of hardy Ferns can be used for planting beneath trees or on steep banks. In some cases it may be necessary to add a little fresh soil to the roots of established plants.

Carnations.—Some of the Perpetual-flowering varieties are most suitable for planting in the flower garden. Plants being grown for this purpose must be hardened off in readiness for putting out towards the end of the month. They should now be growing in frames, where the lights may be entirely removed during favourable weather.

Tuberous Begonias.—Plants which were potted up and started in heat may now be moved to a cold frame. Carefully inure them to the cooler

conditions by judicious ventilation. If frost is imminent, cover the frames with mats.

Staking.—Some of the plants in the herbaceous border will soon need the support of stakes. Let this be done with careful consideration to the habit of the plants. The growths of some of the plants may need a liberal thinning.

The Hardy Fruit Garden.

Early Strawberries.—Where a plantation was made last year on a warm border to supply the earliest fruits, protection from frost will now be needed. The most efficient protection is secured by erecting a rough framework, so that tiffany or something similar may be easily rolled over it. Clean straw placed among the plants to keep the fruits clean can also be used for covering the flowers on cold nights.

Outdoor Vines.—Rub off all surplus shoots when it can be seen which are carrying the best bunches. One of the chief causes of failure in regard to ripening Grapes outdoors is that of allowing the Vines to develop too many shoots, and this fact must be borne in mind when they are in active growth. A sprinkling with some approved fertiliser occasionally will encourage roots to the surface.

The Kitchen Garden.

Lettuces.—To keep up a constant supply of this valuable salad, small sowings must be made at frequent intervals. Prick out plants which have been raised under glass. Most varieties require a distance of a foot apart.

Endive.—This may be sown thinly in rows, and the seedlings thinned out to a foot apart. There is usually not much demand for Endive during the summer months; therefore little space should be devoted to it.

Salsify and Scorzonera.—The requirements of these are identical in regard to their culture. Sow the seeds in rows about eighteen inches apart. When large enough, thin the young plants to 9 inches apart in the rows.

New Zealand Spinach.—This is a useful vegetable, especially during a dry season. Seed may be sown in rows about two feet apart, thinning the plants to the same distance in the rows.

E. HARRISS.

(Head-gardener to Lady Wantage.)

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

Plants Under Glass.

Cinerarias.—The period when the plants are required in flower will rule the time of sowing. For winter flowering, a batch may be sown now in the greenhouse, pricking off the seedlings as soon as they are large enough to handle.

Chrysanthemums.—As the plants increase in height, more head-room must be given them, either by lifting the frames (if portable) on bricks or, in the case of brick frames, by lowering the surface the plants are standing on by the removal of the soil or ashes. Any plants affected by fly should be sprayed with an insecticide, and during fine weather the lights can be kept off, replacing them only in case of frost or heavy rains.

Chrysanthemum Potting Compost.—If the grower has plenty of shed accommodation at command, the compost for the final potting could now be prepared, as it will then be in good condition when it is required later on. The mixture should be kept fairly rough and not made too rich in manures, as far better results are obtained by applying the manure in a liquid form after the plants get established in the new soil.

Violets.—As the plants pass out of flower they may be dispensed with, keeping only a few from which runners can be obtained during August or September. This will clear the frames and allow them to be used for other subjects. The young plants which were put out some time ago will benefit from a syringing in the late afternoon, should the weather be bright and dry.

Bouvardias.—If cuttings were rooted earlier in the season, the plants will now be ready for potting. The Bouvardia thrives in plenty of leaf-soil and sand, and does not like too high a

temperature; in fact, a cold frame from now onwards will suit it splendidly if the lights are shaded during bright sunshine.

The Kitchen Garden.

Runner Beans.—A good sowing should now be made. As slugs and other pests are sometimes very severe on the young seedlings, it will be well to apply a dusting of soot or fine ashes when the seedlings are about to appear on the surface. Apart from their value as a vegetable, Runner Beans may be used with good effect as flowering plants where perhaps a temporary screen is required. Painted Lady is an ideal variety for this purpose.

Celery.—When accommodation in cold frames can be had, the young plants should be given more room by pricking them out 4 inches or 5 inches apart. The syringe must be used freely and the plants shaded for a few days until they recover from the check of removal.

Tomatoes.—Make a sowing to furnish plants that will fruit during the autumn. Plants which are fruiting should receive another top-dressing of loam made rich by the addition of a good fertiliser.

Cucumbers.—If these are to be grown in a frame, make up a hot-bed by mixing clean leaves with some fresh stable litter. After a few days the plants can be put into their places. Ventilation requires special attention when Cucumbers are grown in this way.

The Flower Garden.

Bedding Geraniums.—Like all other bedding plants, these should be well hardened off before being planted out; it is a mistake to keep them too long in the close and perhaps shady conditions of glass houses. Where room in frames can be had, they may be removed there, and failing this, they can be stood in any sheltered position outdoors, where they may be conveniently covered up on cold nights.

Lobelia cardinalis.—This plant, being fairly hardy, may be put out where it is to grow. For preference it likes plenty of moisture, so should the weather be very dry at the time of planting, a thorough watering will be necessary.

Pentstemons may now be safely planted out, whether they are at present growing in pots or on some sheltered border. As some plants may possibly die later, it is a safe precaution to pot up a few of each variety in 6-inch pots, so that any dying plants can be replaced.

The Hardy Fruit Garden.

Strawberries.—It is now time to mulch plants which are fruiting. This not only keeps the fruit clean, but prevents to a great extent the too rapid evaporation of moisture, should the season be very dry. Clean straw is best, if procurable; but before applying it the plants may be given an application of some readily assimilated fertiliser, such as Clay's. Following this, the ground should be gone over with the hoe.

Young Strawberries.—Where the plants are very vigorous, a crop may be taken from the young plantation which was made during August. If, however, the plants are small, it will be to the interests of the crop for next year to remove all the flowers. Encourage a free growth by an occasional hoeing, and if one has the valuable aid of a liquid manure tank, help may be given by applying the liquid in a diluted form during wet and showery weather.

Fruit Under Glass.

Pot Trees.—Such fruit trees as Apples and Pears in pots will be at different stages of development. When the fruits have just started to swell after being fertilised, a judicious thinning should take place, remembering, of course, that there is always a possibility of fruit dropping. This must be allowed for, especially in the case of certain varieties of Pears. The trees which are in a more advanced state of growth and with larger fruits ought to have fairly frequent applications of stimulants. When the grower has not the convenience of an orchard-house, care must be taken that pot trees are not left for long growing in the shade of any other permanent fruit trees.

Castlemilk Gardens, Lockerbie, N.B.

THE CULTIVATION OF PHYLLOCACTI.

[In Answer to a Correspondent.]

THE following notes as to the cultivation of the different Phyllocacti may be of service to your correspondent, and, by following them, the white-flowered kind should be induced to bloom in a satisfactory manner. It is very probable that this is *Phyllocactus Cooperi*.

The Phyllocacti are essentially greenhouse plants, and are more satisfactory if grown in a structure where the winter temperature does not at any time fall much below 50°. At that season of the year they need comparatively little water; that is, just sufficient to keep the soil slightly moist. As with succulent plants in general, full exposure to the sun is very necessary to these Phyllocacti, except just when they are in flower, as the blossoms remain fresh longer when they are shaded.

With regard to the treatment of these plants, I will indicate it from the present time, when the flower-buds make their appearance. The plants should be stood in a sunny part of the greenhouse, and kept moderately watered; that is to say, not always saturated. After the blossoms are over is the best time to repot the plants, a suitable compost for the purpose being made up principally of loam, lightened by a little sand, and leaf-mould or peat, with some brick rubble, broken finely.

It is very important that the pots are quite clean and effectually drained, while at the same time they must not be too large, as Phyllocacti greatly resent a mass of soil around the roots. The compost should be thoroughly mixed together, and, in potting, the soil must be pressed down evenly and made moderately firm. After this work is complete, a good plan is to put a central stake to each plant and loop the shoots thereto in a natural manner; that is to say, just sufficient to keep them from swaying about, and not enough for them to present a bunched-up appearance. A good watering should then be given through a fine rose in order to settle everything in its place. As the roots are at that season active, they will soon take possession of the new soil. If the plant does not need repotting, it will be greatly assisted by an occasional dose of weak liquid manure during the growing season.

Throughout the summer months the plants may be liberally watered, always keeping them fully exposed to the sun. If the greenhouse in which they are growing is shaded, it will, in all probability, be quite possible to group them together at one end and remove the shading from that portion. From midsummer onward, if the space is required, they may be stood out of doors, selecting for the purpose a warm, sunny, well-drained spot. They should be placed on a firm ash bottom, and if at the foot of a south wall, so much the better. Under these conditions, care must be taken that they are not allowed to suffer from the want of water. This treatment will lead to a thorough ripening of the wood, so essential to the formation of flower-buds. Even in the case of newly potted plants an occasional watering with weak, clear, liquid manure will be beneficial when the pots are well furnished with roots. Before the heavy autumnal rains set in, these Cacti should be taken back into the greenhouse. As winter approaches they will need less water, till in the depth of the season they require very little. With the return of spring more must, of course, be given.

These Phyllocacti are in some districts very popular as window plants. In order to grow them successfully in this way, a sunny window should be chosen, and the one thing above all to avoid is allowing water to stand in the saucers in which they are placed. During cold winter nights they should be moved away from the window, as it is the part of the room most liable to be affected by frost.

Practically the only insect pests that give trouble are scale, and these should be carefully removed with a pointed piece of wood as soon as they are seen.

Propagation of the different Phyllocacti is a very simple matter, as if the shoots are pulled out of their sockets with a side twist, they form the best of cuttings, no further preparation being necessary. A length of 4 inches to 6 inches is very suitable for the cuttings. They may be inserted around the edge of a pot 5 inches in diameter, clean, well drained and filled with a compost similar to that recommended for repotting, with the addition of more sand. Late spring and early summer is the best time to insert cuttings. H. P.

BRAMBLES AND THEIR PECULIARITIES.

TO the untrained eye the Bramble and the Blackberry are one and the same thing, but while it is true that all Blackberries are Brambles, yet there are many Brambles which do not produce Blackberries; indeed, some of them produce no fruit at all. Probably there is no plant of our hedgerows so much appreciated as the common Blackberry; at the same time, few, if any, of our native plants have given so much trouble to the botanist, who has endeavoured to cope with all the species and varieties that are found growing wild. There are many little differences and subtle gradations between some species that only the trained eye can appreciate. Those differences may be seen in the number of leaflets which go to make up a compound leaf, or there may be a marked difference in the length of the calyx lobes, or, again, the under surface of the foliage of one kind may differ from that of its nearly ally. Such characters are masked to the casual observer; but the botanist attaches a deal of importance to them, on the ground that half the interest of the plant lies hidden in its structure, which, after all, is a revelation of its past history and development. Herein lies the difficulty of nomenclature, ending in some instances in a hopeless confusion of names. Probably confusion is nowhere more apparent than in the genus *Rubus*, as Brambles are botanically known. The reason is not far to seek, for the plants are so variable that it is often hard to say where one species leaves off and another begins; moreover, the varieties are notorious for the ease with which they cross with one another, thus adding to the confusion. Hybridisation and variation have unquestionably given rise to many forms that have been raised to specific rank in local floras. Some species, however, particularly those which are not indigenous to this country, are quite distinct, and not the least remarkable is the White-stemmed Bramble (*R. biflorus*), native of the Temperate Himalayas. The stems of this Bramble are covered with a white, glaucous bloom, and furnished with strong, recurved prickles. H. C.

TULIP SHOW AND CONFERENCE

FOR THE PURPOSE OF CLASSIFICATION.

THE Council of the Royal Horticultural Society have adopted the recommendation of the Nomenclature Committee to hold a meeting for May-flowering Tulips on May 13 and 14 (cut blooms in vases) for the purpose of enabling the committee to decide on the synonyms of the varieties sent.

N.B.—The trade and amateurs may show groups in the ordinary way, but of Tulips only, with any foliage desired. These groups will be arranged along the walls of the Hall, the centre tables being reserved for cut blooms in vases. It is intended that these cut blooms should be arranged in a series of graduated shades of colour. It is of the greatest importance that every variety of Tulip procurable should be contained in these series. Therefore every exhibitor of a group is requested to provide an extra vase of three blooms of every variety in his group in addition to the vases of any not so included. In cases where it is necessary for the committee to examine a variety closely, these blooms on the tables will be used for that purpose, which will prevent any disarrangement of the staged groups. All British growers are invited to send blooms. A full collection of standard sorts of May-flowering varieties will, if possible, be brought from Holland for comparison. The Royal Horticultural Society's labels will be provided for exhibitors to write their own name and that of every vase of flowers they stage. No other labels may be used. Entry forms for this show can be had on application to the Royal Horticultural Society, Vincent Square. In filling up this form the exhibitor must state how many labels he will require, and these will be forwarded to him so that they may be carefully filled up at home before the hurry and scurry of the staging begins.

Wednesday, May 12.—Begin staging at 12 noon at Vincent Square.

Thursday, May 13.—Staging to be finished by 9 a.m., when the Nomenclature Committee begins its work and conference. None but the committee will be allowed in the Hall after 9 a.m. on this day.

Friday, May 14.—Committee continues its work, 9 a.m. At 11 a.m. amateur exhibitors and two members of exhibiting firms admitted to private view. At 1 p.m. Royal Horticultural Society's Fellows admitted. At 2 p.m. the public admitted on payment of 1s. At 3 p.m. a lecture will be given by Mr. E. A. Bowles, M.A., on "The New Classification for Garden Tulips," illustrated with lantern slides.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send a null scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

THE BARDFIELD OXLIP (J. D. L., D n).—Bardfield Oxlip and Normandy Oxlip are two local names for varieties of the common Oxlip. There is no essential difference between them. As is well known, the common Oxlip is extremely variable in size and form.

HEDYCHUM GARDNERIANUM (E. V. Coakley White).—Culturally, this species is best when treated like the Canna, that is to say, started during the winter in dryish soil beneath the greenhouse stage, started into growth in heat in March, and grown quickly to the flowering stage. The plant prefers a brisk heat—70°—during the summer, and an abundance of moisture and liquid manure when in full growth. It is the strong annual shoots from the base which flower. When the flowers appear, the plant may be put into much cooler quarters, thus ensuring their remaining much longer in beauty. Good rich fibrous loam, with a little peat, leaf-mould and finely sifted manure, should be given with ample drainage. If you have old plants, shake them free of the impoverished soil, repot, and start in brisk heat as above. The flowers are yellow, fragrant, and borne in a dense cone-like cluster a foot long at the summit of the growth. It is a native of the East Indies, and though nearly hardy in this country, is best if grown on the above lines to ensure a good annual flowering. If your plants have been grown in the past or have become weak or deteriorated by reason of wrong treatment, it is unlikely they would flower this year, though they should be grown to that end. The flowering-time is August and September, though it is controlled by the treatment the plant receives. Formerly it was used in subtropical bedding, and may occasionally be so used to-day.

CARNATIONS ATTACKED BY EELWORMS (P. J. B.).

—The only thing that is likely to be successful in warding off the death of the Carnations is a dressing of sulphate of potash at the rate of about 1½ oz. to the square yard, spread on the surface of your soil and forked in. As to the sterilisation of the soil, the most effective method is by the use of steam, but special apparatus would be needed for this work. It might be done by constructing a cement tank of suitable size and about eighteen inches in depth. Run perforated pipes along the bottom and protect them by a perforated metal false bottom from becoming silted up with soil. The pipes might be of about an inch and a-half in diameter, and the perforations an eighth of an inch in rings at intervals of about three inches. Connect the inlet pipe (no outlet pipe is required, though a safety valve might be an advantage) with a boiler, in which steam at a pressure of 60lb. to 80lb. to the square inch can be generated. After filling with soil, the tank should be covered with sackings and steam driven in until the soil temperature reaches about 200° Fahr., leaving it at that for, say, half an hour. The drier the soil, the more rapidly will the desired temperature be reached. The use of formaldehyde (40 per cent. solution) at the rate of one part to 200 part of water will kill practically all the eelworms, but probably some of the eggs may escape.

SEEDS AND PLANTS FOR OLD WALL (W. A. Flower).

The most likely things to succeed on the wall top and take care of themselves in the future are Wallflowers, Snapdragon, Red Valerian (if not too large) and the Yellow Pimpernel, *Corydalis lutea*. The whole of these may be introduced by means of seeds mixed with loamy soil or clayey loam into prepared crevices between the bricks or stones. You do not say whether the wall is of brick or stone, though the latter is greatly in favour of ultimate success. If of brick and the wall has been built with good mortar, much preparation will be required for the sides, particularly in the direction of forming stations and inserting the seed-charged soil. Then, by reason of its dryness and the difficulty of rain reaching the roots of the plants, much subsequent attention would be required in watering and the like. Early autumn is the best time to start the work, because of the atmospheric conditions prevailing at that time. If the wall is of any extent, you might do worse than consult a specialist on the spot. If of small size, we may help you further if you give us a few more particulars. For the sunny side, *Campanula fragilis*, *C. pusilla*, *Houseleeks*, *Linaria alpina*,

L. pilosa, *Aubrietias*, *Thymes* of sorts, *Erinus alpinus*, *E. albus*, *Sedums* and *Encrusted Saxifrages* should do well; for the shady side, small Ferns and *Linaria Cymbalaria*. There are others, but their success depends not a little on the nature of the wall.

TREES AND SHRUBS.

GRAFTING HOLLIES (M. L.).—You would probably experience considerable difficulty in grafting branches of fruit-bearing Holly upon an old non-fruiting plant. Grafts of two year old wood would doubtless unite quite well with the wood of the stock if grafting were carried out in the early spring, but there would be a continual fight between shoots produced from the stock and the grafted portions. When varieties are worked upon stocks of common Holly, quite young plants are used for stocks, and both grafting and budding are practised, the former indoors in the spring, the latter either indoors or outdoors during the summer. If any of your trees produce female flowers, you can get them to fruit by carrying branches of male flowers from another tree and dusting the stigma of the female flowers with pollen. If, however, your trees bear male flowers only, they will not bear fruit.

THE GREENHOUSE.

FLOWERING PLANTS IN A COLD FRAME (A Constant Reader).—You give us no idea of the size and depth of the frame—whether it is 1 foot or 3 feet deep; and unless you have a fair amount of depth, not many flowering plants could be accommodated in it. Exhibition *Chrysanthemums* cannot be well grown in such a frame, and for the summer are best in an open position where all the sun can reach them. Prior to frosts appearing, they should be removed to a well-ventilated greenhouse, where they may receive every attention till the flowering stage is reached. There are many uses to which a cold frame might be put, but as you wish for flowering plants only, you had better give us the size and depth of the frame, and we will do what we can to help you. Do you wish for summer-flowering plants only, or would Violets for winter and spring be of service?

MISCELLANEOUS.

GOLDFISH IN CEMENT TANK (E. W. A.).—A parasitic fungus, a species of *Saprolegnia*, probably *S. ferox*, often attacks goldfish in cement tanks, and is encouraged by hard, chalky water. If the water which runs through the tank is hard, it should be softened by one of the usual water softeners before it enters it. The cement tank, having been in use for four years, is unlikely to be a source of trouble now; but if the fungus increases, have the pond emptied and dried, scrub it out, and coat the inside with one of those artificial stone preparations used for waterproofing the surfaces of stone. It is sometimes found that the fungus on fish attacked may be checked by putting the fish into a bath of *Condy's Fluid*, a teaspoonful of which is dissolved in a pint of water, and a teaspoonful of this used to a gallon of water to make the bath. But affected fish should be isolated. We regret we do not know of any small book dealing with goldfish exclusively, although there are several dealing with fresh-water aquaria.

NAMES OF PLANTS.—A. M. Rose.—*Billbergia nutans*.—Bell.—1, *Ercilla volubilis*. The Ivies you send are varieties of *Hedera Helix*, but we cannot identify them from the specimens.—A. H. E.—*Puschkinia scilloides*.

SOCIETIES.

THE MIDLAND DAFFODIL SHOW.

The magnificent collection of flowers brought together in the Edgbaston Botanic Gardens, Birmingham, on Wednesday and Thursday of last week was a complete justification of the committee's decision to hold the show as usual this year. We do not think a finer display has been seen at any previous show. High quality and rarity of varieties were almost overwhelming, and we wish more visitors had been present to see such beautiful blooms. As usual, the arrangements were perfect, thanks to the organising genius of Mr. Herbert Smith and Mr. T. Humphreys, both of whom never seem to think that anything is a trouble. Herewith we give a somewhat condensed report of the exhibition, and the Rev. J. Jacob, in his "Daffodil Notes," will next week deal with some, at least, of the many outstanding flowers.

GROUP A.—CUT BLOOMS.

OPEN CLASSES.

For a collection of Daffodils, fifty varieties, representing the different divisions, there were four entries, Mr. C. Bourne, Bletchley, being first with a magnificent lot of blooms. Queen of Hearts, Bishop Gore, Kingdown, Dewdrop and Great Warley were a few of his best. Second a beautiful lot of flowers. We specially noted Red Beacon, Great Warley, Red Chief, The Fawn, Gadfly, Ivorine and Homer. Mr. F. Herbert Chapman of Rye was a good third, fourth prize going to Mr. J. Mallender, Bawtry. Six varieties of yellow trumpet Daffodils, Division 1A, three stems of each, brought forth five entries, the premier award going to Mr. F. H. Chapman, who staged Grandsire, Sea Horse and Formula, with three unnamed seedlings, that numbered 50 E 23 being exceptionally good. Mr. C. Bourne was second with fine examples of The Earl, Lord Roberts, The Doctor, Golden King, Queen of the West and Monarch. The third, fourth and fifth prizes

went respectively to Mr. W. A. Watts, St. Asaph; Mr. J. Mallender and Miss Pope, King's Norton.

A similar class for white trumpets, Division 1B, had only two entries, Mr. C. Bourne being first with very clean flowers of Ivory King, Mrs. G. H. Barr, White Emperor, Mrs. Robert Sydenham, Princess and Agatha. Second prize was awarded to Mr. J. Mallender, whose flowers also were very clean and good.

In a similar class for bicolor trumpets, Division 1C, three exhibits were staged, Miss Pope being first with beautiful flowers of Middleton Favourite, Judge Bird, Glory of Noordwijk and three unnamed seedlings; 834 among these was very promising. Mr. J. Mallender was second, his best vase being of a seedling numbered G 30. Mr. C. Bourne was third.

For six varieties of *incomparabilis*, three stems of each, Division 2A, there were only two exhibits, the premier position going to Mr. C. Bourne for some very clean and good flowers. The other exhibit was disqualified by the judges owing to one vase of a wrong section, viz., 3B, being staged.

In a similar class, but Division 2B, there were three entries. The first prize went to Mr. A. M. Wilson for a magnificent lot of flowers, Gadfly and Gay Banner being wonderful. Second honours went to Mr. C. Bourne, who had very good blooms of Lady Moore, Great Warley and Macebearer among his six. Miss Pope was placed third, Lady Margaret Boscawen being her best.

For six varieties of Barri Daffodils, three stems of each, Division 3A, there were three entries, the first award going to Mr. A. M. Wilson, Bridgewater, for magnificent examples of unnamed seedlings. Mr. C. Bourne was second, his *Eschscholtzia*, a very vivid red-cupped flower, being particularly good. Mr. F. H. Chapman was third.

In a similar class, but Division 3B, competition was rather better, five exhibits being staged. The first prize went to Mr. A. M. Wilson, Bridgewater, who had magnificent flowers of Red Chief, Whelp, Red Macaw, Alaric and two seedlings under numbers. Second honours went to Miss I. L. Wilson, who had grand blooms of Capper and some unnamed seedlings. Third and fourth prizes went respectively to Mr. F. H. Chapman and Mr. C. Bourne.

For twelve varieties of Leedsii Daffodils, Division 4, there were three entries, the Rev. J. Jacob occupying the premier position with a good lot of flowers. White King, White Mere, H. C. Bowles, Mrs. W. O. Wolseley and Nana were five of the best. Mr. C. Bourne was second, his best flowers being Bianca, Lord Kitchener and Selene. The third prize went to Mr. J. Mallender.

For three varieties of triandrus hybrid Daffodils, Division 5, three exhibitors competed, Mr. F. H. Chapman being first with beautiful flowers of Alys and two shown under number. Mr. W. F. M. Copeland was second, the third prize being withheld.

In Class 11, for six varieties of *Tazetta* hybrids, Division 8, there were again three entries, Mr. A. M. Wilson being first, all the flowers being shown under numbers. Messrs. Cartwright and Goodwin were second, Rubellite being very good.

Class 12, for nine varieties of true *Poeticus*, included a magnificent lot of flowers, three exhibitors trying conclusions. Mr. P. D. Williams, St. Keverne, S.O., was first, his blooms of Eurydice, Snow King, Tennyson, Sarchedon and Madrigal being exceptionally good. Second honours went to Mr. A. M. Wilson, who had Tennyson in grand form; third, Mr. F. H. Chapman, with seedlings, all under numbers.

SINGLE BLOOM CLASSES.—OPEN.

For a single bloom of a yellow trumpet, Division 1B, Mr. P. D. Williams was first with a magnificent seedling; second, Mr. C. Bourne; third, the Rev. T. Buncombe; fourth, Mr. F. H. Chapman; fifth, Mr. T. Batson.

In a similar class for a white trumpet, the premier award went to Messrs. Cartwright and Goodwin for a magnificent bloom of White Emperor; Mr. P. D. Williams, Mr. A. Wilson, Mr. H. Lee and Mr. C. Bourne following in the order given.

For a bicolor trumpet Mr. P. D. Williams was first with a seedling; second, Messrs. Cartwright and Goodwin; third, Mr. A. M. Wilson.

For an *incomparabilis*, Division 2A, Mr. N. Y. Lower was first with a fine bloom of *Cresus*; second, Messrs. Cartwright and Goodwin; third, Mr. J. Simkins.

In a similar class, Division 2B, Mr. P. D. Williams was first with an unnamed seedling; second, Mr. H. F. Holmes; third, Mr. C. Bourne.

For a Barri bloom, Division 3A, Messrs. Cartwright and Goodwin were first with a beautiful bloom of Mozart; second, Mr. N. Y. Lower; third, Mr. P. J. Worsley.

In a similar class, Division 3B, Mr. P. D. Williams was first with a beautiful red-cupped seedling; second, Mr. C. Bourne; third, Mr. H. R. Darlington.

For the best Leedsii Mr. P. D. Williams was again first with an unnamed seedling; second, the Rev. J. Jacob; third, Mrs. Ridley.

For the best single triandrus hybrid Mr. P. D. Williams was first with Primrose Dame; second, Mr. F. H. Chapman; third, Mr. W. F. M. Copeland.

For a single cyclamineus hybrid Mr. P. D. Williams was first with a seedling; second, Mr. W. F. M. Copeland.

For a single *Jonquilla* hybrid Mr. A. M. Wilson was first with an unnamed seedling; second, Mr. P. D. Williams; third, Messrs. Cartwright and Goodwin.

For the best *Tazetta* Mr. F. H. Chapman won premier prize with a wonderful yellow flower that had a deep red eye; second, Mr. A. M. Wilson; third, Mr. C. Bourne.

For a single bloom, true *Poeticus*, Mr. A. M. Wilson was first with a beautiful seedling; second, Mr. P. D. Williams; third, Mr. F. H. Chapman.

For the best double Daffodil Messrs. Cartwright and Goodwin were first; second, Mr. W. A. Watts; third, Mr. H. Lee.

THE GARDEN.

No. 2268.—VOL. LXXIX.

MAY 8, 1915.

NOTES OF THE WEEK.

A Good Plant of *Lewisia Howellii*.—When in the Royal Horticultural Society's Gardens at Wisley last week we noticed a particularly good specimen of this charming, though to cultivators often vexatious, plant. Three large inflorescences were fully open and twelve others were in various stages of development, with possibly a few others to come.

A New Dwarf *Rhododendron*.—Flowering for the first time in the rock garden at Wisley is *Rhododendron olicifolium*, a dwarf, compact species sent home from China by Forrest. In general appearance it somewhat resembles the well-known *R. racemosum*, but the flowers are larger and more bell-shaped, with a deeper rosy pink colour. It promises to be a very useful species for the rock garden.

Deep Blue and Pale Yellow Flowers.—On a small and rather steep bank near the Wisley rock garden we noticed a charming combination of blue and pale yellow flowers. This had been brought about by planting *Muscari Heavenly Blue* with that beautiful little *Hoop Petticoat Daffodil*, *Narcissus Bulbocodium citrinus*. Such an effect could be advantageously reproduced in many situations, and we record it now so that it may be noted for reference when planting-time comes.

Commission for Mr. T. Percy Peed.—Mr. T. Percy Peed, of the well-known firm of John Peed and Son, West Norwood, has obtained a commission in the New Army. Mr. Peed enlisted in the King's Royal Rifle Corps in the early stages of the war, and was promoted to the rank of corporal. He has now been offered, and has accepted, a sub-lieutenancy in the South Staffordshire Regiment, and entered on his new duties on the 19th ult.

Retirement of Mr. George Massee.—The retirement of Mr. George Massee, V.M.H., from the Herbarium staff of the Royal Gardens, Kew, on account of the rules regarding age limit, will cause regret among many Old Kewites. In 1893 he succeeded Dr. M. C. Cooke in taking charge of the Cryptogamic Department, where fungi of all kinds received his special attention. As an author Mr. Massee was very active, and his books on various plant diseases and fungi generally are known all over the world.

Our Sub-Editor Wounded in Action.—We regret to state that our Sub-editor, Mr. H. Cowley, who has been "somewhere in France or Belgium" with the 12th County of London Regiment since Christmas Day, has been wounded. Happily his injuries are not severe, as the following extracts from a post card written by him on the 25th ult. will show: "For the past eight days we have been in severe battle. I am slightly wounded by shell—only a bruised rib, and am in hospital. I expect to return to battle in a day or two. Dreadful warfare is still raging. It is a great struggle—we *must* win." All who know

refined, both in shape and colour, the interior of the flower being white, while the outside of the petals ranges from light blue to purple. It is by no means a new plant, but one that is seldom seen, and is excellent for the shady parts of the rock garden. The accompanying illustration represents a colony of a beautiful form of *Anemone blanda* growing in the rock garden at Wisley. The corms were, we believe, collected in Asia Minor. The flowers are large and exceptionally good in colour.

The Value of *Aubrietias*.—As a class the *Aubrietias* are among the indispensable subjects of the spring, coming and going each year, and requiring very little attention. They are now in full splendour, the tufts being masses of colour, almost hiding the foliage. There are many really fine sorts now in commerce, Dr. Mules, Fire King, Crimson King, Mrs. Lloyd Edwards, Model, Moerheimii and Leichtlinii being among the best. Where space for them is somewhat limited, they may be cut back hard as soon as the flowers are over. This will give them a close, compact habit and produce plenty of young growths for cuttings.

Briar Wood for Pipes.—According to the current issue of the *Kew Bulletin*, which quotes the Diplomatic and Consular Report, a considerable industry has arisen in Corsica during the last few years in the cutting and exporting of blocks for pipe-making, 523 tons of these little blocks being exported in 1912. "Briar wood is obtained from the Tree Heath (*Erica arborea*), and the pipe blocks are cut from nodules which form on the roots. These nodules are very hard, and vary considerably in size, many being from 9 inches to 12 inches in diameter. The burr-like character of the wood presents a singular appearance

A CHARMING FORM OF THE GRECIAN WINDFLOWER, *ANEMONE BLANDA*, IN THE ROCK GARDEN AT WISLEY.

Mr. Cowley will join us in hoping that his wound is not more serious than he indicates, and will appreciate the characteristic touch of the last three words, "we *must* win."

A Beautiful *Anemone*.—The Grecian Windflower, *Anemone blanda*, that is so beautiful in our gardens at the present time, is among the most prized of the hardy flowering plants. It matters little whether the flowers are the fine blue of the type or one of the several forms which vary from white to deep purple. The beautiful variety *scythica* is later in coming into bloom than some of the forms. The flowers are large and most

by reason of the twisted fibres, and when filled and polished is often very beautiful. *E. arborea* is known as a large bush 15 feet to 20 feet high, with tiny dark green leaves, and in March and April as a decorative flowering plant of the first quality, the small, fragrant white blossoms being produced with the greatest freedom. It succeeds well in the South of England, and several large masses of plants 5 feet or 6 feet high are among the most prominent floral effects at Kew during the spring months. The English name 'Briar' is a corruption of the French word 'Bruvère,' meaning Heath."

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Recipe Wanted for Making Elder-Flower Water.—Can any of your readers give me a recipe for making Elder-flower water?—LADY N.

Cabbage Sutton's Harbinger.—I have been much impressed with this variety during the present season. Sown on July 16 last and planted on a northern slope on September 9, it was ready for cutting the first week in April. The stock proved to be perfectly true, quite distinct, and not one plant showed signs of bolting. It is an invaluable Cabbage to all cultivators.—E. BECKETT, V.M.H.

A Tall Specimen of Berberis Aquifolium.—In answer to Mr. C. Comfort's enquiry, there is a plant of the above in a shrubbery border in Kensington Gardens, London, at least between 6 feet and 7 feet in height and from 3½ feet to 4½ feet in width. I saw it last Easter Monday, when it was carrying some excellent heads of flowers, and I happened to mention to my wife, who was with me, that it was the finest plant of its kind I had seen.—C. T., Highgate.

Flowering Sprays of a Rare Tree from Lancashire.—Mr. F. A. Fenner, Holker Hall Gardens, Cark-in-Cartmel, Lancashire, sends us flowering sprays of *Laurelia aromatica*, or *L. serrata*. In writing he states that the tree is 23 feet in height, with a 15 feet spread of branches, and that it is flowering profusely this year. This tree is a native of Chili, and is by no means common in this country, the best specimen we know, a fine tree 50 feet high, being in the gardens at Penjerrick, Cornwall. When crushed, the foliage, which is deep, glossy green, emits a decided fragrance resembling that of the Bay Laurel. It has hitherto been considered hardy only in the milder south-west counties of England and in Ireland, and we congratulate our correspondent on his success in growing and flowering it in Lancashire. The accompanying illustration of a spray gives a good idea of the size and shape of the flowers, which are greenish yellow in colour.

Cytisus fragrans.—The note on this *Cytisus* in THE GARDEN for March 6 recalls to my memory some very fine specimens in the Temperate House at Kew about forty-five years ago. The foreman of the Temperate House at that time was Mr. Andrew Dick, a gardener of the old school. He set to work to grow some specimens of this *Cytisus* as he had seen them grown in his younger days, and I must say he produced some very fine plants. They were raised from seeds, and, as they grew, the main shoot was secured to an upright stake. It was not stopped in any way, but as it grew pushed out side shoots freely, so that some of

the plants at least formed almost perfect pyramids. Speaking from memory, I should say the plants were from 8 feet to 10 feet in height; but it is quite possible, after that lapse of time, to make a mistake. However, there is no question as to the large size attained by the plants and their great beauty when in flower, in which condition they were admired by everyone. Another plant that the same cultivator was very successful with was *Fuchsia splendens*, of which he used to grow large specimens full of bloom. With regard to the *Cytisus*, although *fragrans* is now regarded as the correct specific name, it is far better known

FLOWERING SHOOT OF *LAURELIA AROMATICA*, A RARE TREE FROM CHILI. A SPECIMEN HAS FLOWERED THIS YEAR IN LANCASHIRE.

as *Cytisus racemosus*, while it is the *Genista* of the market-growers, by some of whom it is cultivated in large numbers, and in the season forms a very conspicuous feature on the costermongers' barrows in the streets of London.—H. P.

Treatment of Bouvardias.—I was interested to see a note on these beautiful greenhouse plants on page 205 of May 1 issue. In addition to stem cuttings, I have practised the taking of root cuttings for several years. Small pieces of root, taken off in early spring and planted in a pot of sandy soil, quickly make good plants for flowering the following winter.—A. B. ESSEX.

An Inexpensive Wall Garden.—The discussion on "Undesirable Plants in the Rock Garden" affords a valuable excuse for writing under the heading, for the two principal subjects of controversy, *Arabis alpina* and *Cerastium tomentosum* are two of the finest, though the commonest plants for this purpose. Their rampaging (I thank the controversialists for teaching me the word) qualities are in this connection valuable assets. No one can fail to admire these beautiful plants, yet in a small rock garden they must, the enthusiast, give place to rarer plants. But surely we are not bound to ban them entirely

from the garden or to limit them to the doubtfully artistic rôle of edging plants. Their inclusion in the wall garden is a welcome compromise. They will drape a dry wall to a considerable depth, and as the dry wall is usually footed by a hard path, the encroachment on this can be tolerated or stopped, according to the will of the owner. The plants I here mention as suitable for the wall garden are all easy to grow and give fine floral results, and once they are established they need less attention than plants in other situations. Beyond occasional weeding and trimming off of dead foliage and stems, the wall garden can very well take care of itself, for even in a dry summer no watering is needed if a good back run of soil is provided, and especially if a sloping face is given to the wall. I recommend readers to try their skill first of all with the following plants. Choice kinds can be added as the reader becomes familiar with their requirements by their behaviour in the rockery. The Rock Pinks are fine for the purpose, as are also most Saxifrages. Even the old-fashioned London Pride may find a place. *Aubrietia*, of course, is indispensable, and *Alyssum saxatile* gives a fine glow of golden colour. I have not yet tried *A. argenteum* for the purpose, but its habit seems to indicate its suitability. Sea Pinks and Rock Roses are sure to do well. There are also many Sedums suitable, notably *S. ibericum*, and I fancy *S. spectabile* would also do splendidly. *Nepeta Mussinii* is an old and tried favourite. Rock Roses and *Viola cornuta* must be included also *Santolina*, *Rosemary* and

most probably *Southernwood*. *Phlox subulata*, *Veronica rupestris*, *Iberis sempervirens*, *Arenaria montana*, *Draba aizoides*, *Anthemistinctoria*, various kinds of *Campanula*, *Centranthus ruber*, *Snappedragons*, *Wallflowers*, *Linum flavum* and *L. perenne*—all these may be expected to do well if given a fair start. There is hardly any garden where a praiseworthy excuse cannot be found for the making of a wall garden. Whatever the aspect, and whether shaded, sunny, sheltered or exposed, we can always find suitable plants to adorn such a wall.—WILLIAM F. ROWLES.

The Fritillary as a Wild Plant.—In "H. C.'s" interesting article on "The Charm of Common Spring Flowers" he mentions the Fritillary. It is readily grown in the garden and sows itself freely, the white variety more freely than the chequered. Let me suggest to your readers to grow it from seed. It is grievous to see this flower in Oxford Market, tied up in stiff bundles so as to quite destroy its graceful beauty, and, again, gathered in handfuls by the village children and not seldom thrown aside to wither. My friend Mr. Potter assures me that gathering the flowers year after year in tens of thousands must lead to the diminution and, finally, to the extermination of the flower, as it is prevented from increasing in the natural way by seed. I fear that the ruthless plucking of the flowers is more harmful to the Fritillary than to other bulbous plants, because it has so little foliage besides that on the flower-stalk. The sight of a Fritillary meadow in bloom would be still more delightful if the flowers were allowed to seed, as we should then have a sheet of bloom. I wish that the owners of some of the meadows would keep them carefully preserved from gathering and allow us to see them when in full bloom.—F. A. STURGE *Coed Efa, near Wrexham.*

Sparrows and Gooseberry Flowers.—On page 193 of THE GARDEN for April 24 there is a note referring to sparrows and Gooseberries. The sparrows are spoken of as destroying the flowers of Polyanthus, Primroses, Sweet Peas, Gooseberries, &c. A few years ago I noted the same thing, also that they bit them only, never eating them, but leaving the pieces of destroyed flowers on the ground around the plants. It seemed to be moisture in the flowers and leaves they were after. That idea was acted upon. They are no trouble now. They are welcome in the garden. Pieces of fat are hung up for the tits, and crumbs are thrown out for the sparrows, and they are hourly visitors. Sometimes both the sparrows and the tits are seen on various plants, but they do no harm. It is thought they are seeking insects. They are never disturbed. The immunity from harm is secured by providing the moisture the birds need; but the water must not be placed on the ground. The sparrows are too suspicious of the gardener's enemy (the cat) to use it there. It must be mounted on a pedestal 4 feet or 5 feet high, say, a piece of quartering with brackets at the top to support a painted tin or iron bowl about ten inches across. If the tin or iron is not painted, the water will become stained with rust, and the birds will not use it. The robins are very often seen having a long bath in it. It should be very shallow.—O. N. E. ANOTHER. [We thank our correspondent for his letter, but regret that the sparrows with which we have to contend are not so considerate as his. Water and food they have in abundance, yet they ravage every choice plant that is available.—ED.]

Undesirables in the Rock Garden.—As I have hitherto taken no part in the interesting correspondence which has appeared in THE GARDEN, I am possibly in a better position to offer a few remarks on a recent contribution to the controversy—a remarkable letter which appeared in your issue of April 17 over the signature of "Anne Amateur." From it one must only conclude that its writer has never seen any of the many hundreds of gardens in the kingdom in which alpines are grown and appreciated—not

necessarily rock gardens, but even in rock-edged borders and in plain soil. "Anne Amateur" is horrified that "undesirables"—strong-growing, rampagous plants—should be "cribbed, cabined and confined" for the benefit of their weaker neighbours. Some of the suggested methods of restraint were, no doubt, drastic; but the gardener with limited space at his disposal finds great difficulty in keeping within reasonable bounds plants like Cerastiums and Linarias, which—not content with ramping above ground—run for yards under soil and rocks to reappear among choicer things. Personally, instead of endeavouring to restrain these invaders, I have tried as far as possible to replace them by plants of similar appearance but less invasive habit, as, for instance, substituting *Arenaria montana* for Cerastiums. But some plants are not easily replaced, and if one grows them and they encroach beyond reasonable bounds, the ordinary gardener endeavours to limit their encroachments as best he can. Not so "Anne Amateur"; her flowers shall "freely grow and blow at their own sweet will"! I wonder if "Anne Amateur" has ever grown some of the more rampant herbaceous plants, such as *Campanula rapunculoides*, *Polygonum sachalinense*, the taller *Linarias*, *Asters* and *Helianthus*. From the above quotation from her letter one can only presume that she has not, and I would therefore suggest to her as a pleasing experiment that she should plant some of each of these in a bed and let them "freely grow and blow at their own sweet will." I can assure her that at first they will magnificently fulfil her expectations and will grow freely, though as time passes, in their struggle for existence, they will not be able to blow as freely as she and they might desire. I cannot give her the name of the ultimate winner of this titanic struggle, but it should be a close thing between the *Linaria* and the *Polygonum*. Of this, however, I am sure: when she tires of the experiment she will require a pickaxe to break up the tangle of roots she will find in the bed and surrounding grass. Fortunately, "Anne Amateur's" ideal garden is not often seen. I recollect such an one—a jungle which was usually described as "Mrs. —'s very wild garden." The average gardener is happily content to grow all sorts and conditions of plants, restraining the encroachers and encouraging the compact growers. He cares for his plants as a benign parent might care for his children, restraining the strong and encouraging the weak. May the day be far distant when he will be applauded for leaving the weaklings to fight unaided their unequal battle for existence! The discussion in THE GARDEN has at least had one effect: it has caused "Anne Amateur" to resolve that she will not grow alpines. In the circumstances it is a resolution to be commended. Long may she keep it, for so long will the glorious gems of the mountain world be saved from that certain death by strangulation to which "Anne Amateur" would consign them in her tangled wilderness.—M. H.

FORTHCOMING EVENTS.

May 11.—Royal Horticultural Society's Meeting and Exhibition, Vincent Square, Westminster, 1 to 6 p.m.

May 14.—Royal Horticultural Society's Exhibition of Tulips, Vincent Square, Westminster. Fellows admitted at 1 p.m.

May 18.—Royal Horticultural Society's Chelsea Show (three days).

ROSES IN A WEST LOTHIAN GARDEN.

NOT for many years have we enjoyed such a fine summer and autumn in this district as we did in 1914, and the great bulk of garden flowers were exceptionally fine. Roses, early in the season, gave great promise, and certainly the first crop of bloom was everything that could be desired, except that its duration was very short, owing to the dry, sunny weather experienced at the time. The second growth was early and vigorous, and our hopes ran high, expecting to beat our fine record of the previous autumn. Alas! at the end of July we experienced a week of exceptionally cold weather, the thermometer on several nights dropping to 40° or under (on two occasions 38° were registered). The low temperature, accompanied with heavy rain, brought on a severe attack of mildew, which we found impossible to effectually check.

The result was, therefore, a disappointingly poor crop of autumn blooms. Only a few varieties were anything like satisfactory. Even that hitherto unbeatable autumn Rose, Gustav Grunerwald, gave only a very moderate number of good blooms. I am glad to say that, as usual, General Macarthur was the best Rose in the garden, and even on September 28 was making a brave show. Almost equal in excellence was Mrs. E. Powell. This showed but very slight traces of mildew, its glossy, leathery foliage seeming to resist the scourge better than most. Curiously enough, Château de Clos Vougeot was finer than usual, the growth being much more upright than ever before, and the flowers opened well. Rayon d'Or also flowered well, the colour being very clear and brilliant. Lady Ashtown gave some good blooms quite late in autumn, while M. Paul Ledé also had a few exquisitely coloured blooms of good size.

Another fairly satisfactory variety was Mme. Second Weber. This was exquisitely fine at the first blooming. Another Rose that did quite well in autumn was Laurent Carle. The blooms were large and much brighter in colour than usual. Mrs. David McKee, although not over-floriferous, gave some exquisite blooms. Beauté de Lyon, though entirely mildew-proof, is yet a useless garden Rose. The colour is wonderful, but the blooms last only about a day and are very sparingly produced. Lyon Rose was poor in autumn, but more than usually fine at the first blooming. The habit of this Rose is slightly improving here.

The following varieties were very poor last autumn, although more than usually fine in July: Mme. Mélanie Soupert, Mme. Maurice de Luze, Pharisæer, George C. Waud, Mrs. A. R. Waddell, Liberty, Mme. Ravary, Le Progrès, Hugh Dickson, J. B. Clark (exceedingly fine early in the season), Mrs. John Laing, George Dickson (not a very free bloomer here), Edward Mawley, Mrs. R. G. Sharman Crawford, Caroline Testout (extra fine), Viscountess Folkestone, Mrs. W. J. Grant, Betty, Clara Watson, Harry Kirk, Killarney, Kaiserin Augusta Victoria, Marquise de Sinety, Mrs. Aaron Ward, Richmond (better than usual), Rosomane Gravereaux, Warrior, White Killarney and Ulrich Brunner.

Preston House Gardens, Linlithgow. C. BLAIR.

DAFFODIL NOTES.

BY THE REV. JOSEPH JACOB.

The Midland Show.—"Birmingham" has once more come and gone. It is said that in the Civil War in England in the seventeenth century, operations of husbandry went on in some parts quite as usual until the presence of the contending forces on the next farm revealed the stern reality of war in their midst. So it seems to be to-day with the Daffodils. They came to Birmingham from Ireland, Cornwall, Wales, Holland and the Midlands as if there was no such thing as fighting. The presence in khaki of The Brodie of Brodie and Mr. H. G. Hawker might have been the first inkling they had of the fierce conflict in which we are engaged; they looked so much as they always look in their tiered unconcern.

Yes; the flowers were there just as in past years. Fewer cups and eyes perhaps, but, on the other hand, more trumpets. No Engleheart and no Crosfield, but more and better than ever before from Barr and Wilson. No competitors, it is true, for the Cartwright Cup for twelve new varieties that have not been in commerce more than four years, but they fully atoned for this delinquency by their rally round the "home-made" seedling classes, while they verily mobbed the open "fifty" and the amateurs' "twenty-four." No Sydenham to hospitably entertain us—only a semi-public dinner, but with "conversations" afterwards which have never been surpassed for freedom of speech and general interest.

From all these facts readers will infer, and infer truly, that if there were hiatuses, there were also compensations, and that the Midland Show of 1915—notwithstanding war and weather—was no whit inferior to its predecessors. In some ways it differed. Messrs. Barr and Sons entered in several of the classes for seedlings and new varieties, and did not return home empty-handed. Now, Mr. Pearson, Mr. Coey, Mr. Leak, Mr. Ware, you have had a lead; won't you follow suit next year? Mr. A. M. Wilson is, I know, a *very* hard nut to crack, and now that he has got into his stride he will always take a lot of beating; but British troops stand up to "Jack Johnsons." There is plenty of ammunition of the best and latest pattern being made at Shovell; but I fancy the manufactories at Lowdham, Donard, Wisbech and Inglescombe have not been idle of late, and who knows what surprises they may have in store! Among the non-competitive groups one was glad to see that of the Donard Nursery Company from Ireland, for the second year in succession. Had it been better put together and stiffened with choicer varieties, it would doubtless have gained a higher award. That splendid Daffodils can be grown there was shown by the grand King Alfreds, which occupied a central position on

THE NEW NARCISSUS MOZART, WHICH RECEIVED AN AWARD OF MERIT AT THE BIRMINGHAM SHOW. (See page 221).

the stand. One cannot pass by without comment the new roof of what is called the Exhibition Hall, but which is really only a continuation of the conservatories in which the show is held. Mr. W. H. Whitelock, who is the chairman of the Botanical Gardens Committee, told me that he was anxious to keep our Midland Show at the Gardens, and that he hoped the re-roofing had made us more comfortable. I thought it a distinct improvement. The accustomed place of Engleheart knew him not, I regret to say. One had hoped that after the miss at London, Birmingham would have been possible; but it was not to be. The absence of his group was a distinct loss which everyone felt. Birmingham without Engleheart somehow was not the Birmingham of old. I sincerely hope that this second miss does not mean the great veteran's retirement from show life. Our president, Mr. P. D. Williams, was not able to come himself, and we had to be content with his understudy and with some very fine flowers, which, among other achievements, carried off the Bourne Cup to Cornwall. It was very pleasant to see Mrs. E. M. Crosfield in the absence of her husband. After astonishing the good folk in the Forest of Dean, he was resting on his laurels and enjoying a quiet day's fishing at his newly found home near Chepstow. I hope he does not intend to follow the example of Diocletian and retire

I mean. Our New Zealand friends did not like to see so many blooms shown unnamed. I presume we all think much the same, but as no one yet has invented a feasible plan of naming *all* new varieties, we feel we have to make the best of things as they are.

As several visitors were unaware that there was to be a dinner at Birmingham on the evening of the first day of the show, I would like to take the opportunity of saying that the society intends, in accordance with a resolution passed on the evening of the first day of the 1914 show, to make this an annual affair.

New Flowers.—It is always difficult at a show to say which are the best flowers; tastes differ so much that a unanimous agreement is impossible. It is an easier task to single out the most novel. I think the variety that might be so described was

Cicely, a neat, cup-shaped Jonquil hybrid of good form and with most remarkable colouring, the perianth and corona both being of a buff or almost apricot colour. Perhaps Sundew and Centaur were the runners-up. I append descriptions of some of the best and most striking.

Centaur (A. M. Wilson), shown in Class 37 for the White Daffodil Trophy, is a fine bloom of good substance and shape. The whole flower is of a uniform whiteness and has a beautiful clean-cut look. D, $3\frac{1}{2}$; S, $1\frac{1}{2} \times 1\frac{1}{2}$; C, $1\frac{1}{2} \times 1\frac{1}{2}$.

into private life. The palace and garden at Spalato must have been *very* tempting; so, no doubt, is a good stretch of a good river; but Daffodils—

The Dinner.—The first one without our founder, Robert Sydenham, passed off very well. We all tried to dine as usual, knowing that this would have been his wish. About thirty of us sat down to an excellent little repast, fortified by which nearly everyone got on his feet and talked Daffodils. It was only time that prevented it being a regular round-robin affair, for, alas! in the midst of our treasurer's (Mr. C. L. Adams) remarks, eleven o'clock came and cut him off.

The presence of Professor Thomas from Auckland, New Zealand, and Mr. Wilson, now of Somerset, author of a charming little work, written from his *personal* experience, entitled "The Narcissus at the Antipodes," gave a piquancy to the proceedings which we all relished. We saw ourselves as others see us. We were told that triandrus hybrids were a mistake, as none rivalled the wild species. We heard that we were hardly particular enough about refinement and attached too much weight to size; and so on.

One suggestion deserves particular notice—a "bantam" class! Why not? It would be of great interest to have one in which the diameter of the bloom was limited to 3 inches, as it would provide an opening for many flowers that otherwise would open and bloom unseen at shows. Pure Gold, Wendy, Eoster, Ruby and Little Joan are types of what

Sundew (Barr), a giant, star-shaped incomparabilis of great size and lovely texture. The perianth is a uniform primrose and has very pointed segments. The corona is yellow and but little expanded. Dimensions: D, $4\frac{1}{2}$; S, $1\frac{7}{8} \times 1\frac{1}{2}$; C, $1\frac{3}{8} \times 1\frac{3}{8}$.

Mozart (Brodie), one of the flowers which gained an award of merit, is a very shallow-cupped incomparabilis of good substance and with much imbricated segments of a good shade of primrose. The cup is deep yellow and has a well-defined edge of red, which here and there runs in towards the centre as if the brim was composed of three or four large scallops. Dimensions of bloom: D, 3; S, $1\frac{1}{4} \times 1\frac{1}{4}$; C, 1. This was shown by Cartwright and Goodwin.

Gascon (A. M. Wilson) is a giant incomparabilis which looks even bigger than it really is, notwithstanding the perianth *slightly* reflexing. In its natural pose the flower has a diameter of $4\frac{1}{2}$ inches, but when the segments are placed at right angles to the corona it becomes $4\frac{3}{4}$ inches. The reflex relieved the "hit-me-in-the-eye" look which otherwise it would have had. It is a seedling from Princess Mary. Perianth, maize, inclining to a more lemon colour near the cup, which is a deep yellow suffused with orange red, the shade deepening towards the margin. Size: D, $4\frac{1}{4}$ (or $4\frac{3}{4}$ when flattened); S, $2 \times 1\frac{3}{8}$; C, $1\frac{1}{8}$.

Rochester Quinton (Chapman) is a charming flower which, notwithstanding its size, may be

called pretty. It is a seedling from Firebrand crossed with Swashbuckler, and comes under Class 2B. Perianth, white, with some green towards the base of the cup; cup, Nelsonii shaped, with a wide margin of red dissolving into a green centre. D, $3\frac{7}{8}$; S, $1\frac{1}{2} \times 1\frac{1}{4}$; C, $\frac{5}{8} \times 1$.

Puritan Maiden (Pearson), an exquisite, up-setting flower. She has two suitors for her hand, Mr. Trumpet and Mr. Leedsii; both want her, and I do not wonder. The flower is the result of a secondary cross of some of Pearson's well-known Leedsii. Perianth, pure white; cup, pale cream, with a pretty recurving brim. D, $3\frac{3}{8}$; S, $1\frac{1}{2} \times 1\frac{1}{4}$; C, $1\frac{3}{8} \times 1\frac{1}{2}$.

Chapman's First-Prize Poetaz in Class 24 is the result of a cross between Chaucer and Jaune à Merveille. There were two large, smooth, round flowers on the stem, which looked like pale yellow Poets. It is a decided advance. Size of the flowers: D, $2\frac{5}{8}$; S, $1 \times 1\frac{1}{4}$; C, $\frac{3}{4}$.

White King (Mallender), a very shapely Leedsii, with a smooth, flat perianth which keeps its shape even in old age. Perianth, very flat, well imbricated, pointed; cup, expanding, pale primrose. D, $4\frac{1}{4}$; S, $1\frac{5}{8} \times 1\frac{1}{4}$; C, $1\frac{1}{4} \times 1\frac{5}{8}$. An excellent show bloom.

Of course, these must not be taken as all the good new flowers at Birmingham. As I have already hinted, there were so many that the average visitor must have wondered what the future of the Daffodil is to be.

AURICULAS FOR THE OUT-DOOR GARDEN.

IN the spring months, when our gardens are filled with dancing Daffodils, gorgeous Tulips, modest Primroses and Sweet Violets, as well as lots of other sweet-smelling or brilliant-hued flowers, it is not surprising that the modest Auricula has to a great extent escaped attention. Yet a few well-grown plants of the section known to nurserymen as 'alpine Auriculas—to distinguish them from their more aristocratic brethren that are only suitable for exhibition purposes—possess a subtle charm that seldom fails to fascinate the average flower-lover.

The history of the Auricula that we know to-day has been a somewhat chequered one. Although grown in our gardens in Queen Elizabeth's time, it was not until about the middle of the seventeenth century that the Auricula began to develop those delightful colours that raised it to a pinnacle of fame, and it was not until a century later that the first edged or show Auriculas were raised. Towards the end of the eighteenth century plants of the latter class were making large prices, and from that time onwards until well into the Victorian Era the show Auricula occupied a position in the front rank of what were termed "florists' flowers." With the development of artistic ideas and

the demand for flowers suitable for the outdoor garden, the show Auriculas fell into disfavour, and it is unlikely that they will ever regain their erstwhile proud position. At the present time they are cultivated by only a few enthusiasts in this country, who appear to understand perfectly their few likes and dislikes.

When those whose business it was to raise new Auriculas realised the trend of public taste, they wisely turned their attention to the alpine section as being suitable for cultivation in the outdoor garden, with the result that among them we now have flowers of exceptionally rich and soft colours, large size and good substance, and, above all, that subtle fragrance without which the Auricula would lose the greatest of its charms.

Unfortunately, the erroneous idea has become prevalent that all Auriculas are difficult plants to grow, and that they need a great deal of protection and attention to bring them to perfection. No doubt this false idea has to some extent been due

proportion of sand, and the seeds must only be lightly covered with clean sand; they are very small and germinate slowly, hence the necessity for shallow sowing, porous soil and thorough drainage. After sowing the seeds, each pot or pan should be stood in a shaded cold frame and covered with a sheet of glass. The seedlings ought to be pricked out separately into shallow boxes or pots filled with fine, porous soil as soon as large enough to move easily, and about fourteen months after sowing, or even earlier if preferred, they will be strong enough to go into their flowering quarters outdoors.

It is in the selection of a permanent place for outdoor-grown Auriculas that some care is needed. They appear to prefer cool, rich, yet well-drained soil, with a light overhead shading from brilliant sunshine. I used to grow them in rather heavy, thoroughly dug soil under the thinnest portions of old Apple trees, well away from the trunks, and also out of the way of excessive drip from the

out in September or for flowering in pots in the conservatory in spring. If grown perfectly cool, the alpine Auriculas make charming pot plants, and their delicious fragrance finds favour in the spring in both conservatory and dwelling-house.

Such, briefly, is the cultivation necessary for one of our oldest flowers, the "Dusty Miller" of our gardens, and one that deserves greater attention from flower-lovers than it receives at present. As with many other beautiful flowers, cottagers have all along realised its merits, and some of the finest alpine Auriculas in existence may be met with in old cottage gardens far outside the sphere of modern civilisation. W. H.

HARDY BAMBOOS AND THEIR CULTIVATION.

THERE are few subjects that add so much grace and beauty to a garden during the autumn and winter months as the hardy Bamboos. Well-grown specimens create an imposing effect, and impart a decidedly tropical aspect to the garden, especially those of the *Phyllostachys* section. It is essential to give the plants sheltered positions where they can receive protection from the cold winds, which do more harm to the foliage than frost. Bamboos are seen to advantage against a background of dark green, such as is provided by a group of Hollies, and there are few gardens where it is not possible to find such a position for them.

The Best Soil.—They succeed best in moist, loamy soil, which should be deeply cultivated beforehand, and in most cases some well-rotted farm-yard manure should be incorporated with the soil.

When to Transplant.—May is the best time to transplant, and it is also a suitable period to plant out young specimens from pots, although this may be done at any time during the summer. It is important to water young plants during hot, dry weather, and even established specimens derive much benefit from occasional thorough soakings during a dry summer. When planting, it is well to remember that the

Arundinarias flourish most in partial shade; but those of the *Phyllostachys* group prefer more sunshine, and will not succeed if heavily shaded by trees.

Mulching.—It is desirable to apply a mulch of well-rotted manure in May or early June, as this helps to conserve moisture in the soil, and subsequent waterings wash the manurial properties down to the roots. Bamboos succeed admirably on the banks of a stream or lake where their roots have the benefit of moist surroundings, and in such positions they look very graceful overhanging the water. On the whole I find a hot summer suits Bamboos the best, provided they are suitably supplied with moisture as they then make vigorous growth.

The Best Varieties.—There are probably about forty varieties in cultivation, and of these I propose to mention the best for general planting. As is well known, most of the Bamboos are natives of

A VIEW IN THE HARDY BAMBOO GARDEN AT KEW. NOW IS THE TIME TO PLANT.

to the elaborate precautions and wonderful soil mixtures that florists of the old school used to adopt in growing plants of the show section. These Auriculas certainly needed, and still need, protection from heavy rains to preserve their delicate farina intact, though the plants of these, and indeed all Auriculas, are perfectly hardy. As already mentioned, the alpine Auriculas are well adapted for growing in the open garden, and if seed is purchased from a good source, a colony of plants, rich in colour and strong in constitution, may be raised with the aid of nothing more elaborate than a cold frame.

Some difference of opinion exists among growers as to the most suitable time for sowing the seeds; but if other circumstances are favourable, one cannot go far wrong in following the dictates of Nature and sowing it as soon as ripe, which is usually about mid-July. The soil used for filling the seed-pans or pots ought to contain a good

overhead branches. This soil was heavily manured with old cow-manure, to which a good proportion of very coarse sand had been added, and in this the plants thrive amazingly. A simple method of propagation that used to be adopted, and which answered perfectly well, was to take away the young, non-flowering shoots or offsets as soon as the plants had finished flowering, and these were planted in a shady place outdoors similar to that already described, and well watered for a week or two. After this necessary mutilation the old plants received a good mulching with dry cow-manure, which imparted remarkable vigour to them and induced them to give us a rare floral display the following spring, when the offsets also would throw a few trusses of large blossoms. The average gardener does not care to risk planting offsets of choice plants in the outdoor garden, and so inserts them in pots filled with good soil and grows them on in cold frames, either for planting

China and Japan, and of these *Arundinaria japonica* (Métake) is one of the most popular and useful, as it is especially hardy and vigorous. *A. nitida* is a distinct and lovely species, with purple black stems and small, lanceolate leaves. It makes an ideal specimen for the lawn. With us it has attained a height of 15 feet, and is very symmetrical in habit. *A. nobilis* is a grand Bamboo, and attains a considerable height; while *A. Simonii* is a handsome plant, which soon reaches large proportions.

There is some doubt about the origin of *A. anceps*, but it is probably a Chinese species. It is certainly one of the best Bamboos, and should be grown by all. The golden variegated foliage of *A. auricoma* renders it particularly attractive. It is one of the best dwarf kinds, of which *A. Fortunei* and *A. Veitchii* both merit a place, the broad leaves of the latter having variegated edges. *Bambusa palmata* is distinct and handsome. It spreads rapidly, and is an ideal plant for the wild garden where it has space to extend. The large leaves are a vivid green above and a glaucous hue beneath.

In the *Phyllostachys* section, *P. aurea* is an ideal plant for grouping. It is an erect grower and of a fairly dense habit. The black stems of *P. nigra* render this Bamboo very distinct. *P. mariacea* is rather uncommon, but is a noble plant with dark green stems that arch pleasingly. In *P. viridi-glaucescens* we have a beautiful species with an elegant and graceful habit. It is perfectly hardy, and its leaves always retain their fresh green colour. *P. fastuosa* is a stately Bamboo of vigorous, upright habit. The stems often reach a height of 20 feet, and form a stately feature among dwarf-growing varieties. This is probably the most handsome Bamboo that is hardy in our climate. *P. Quiloi* is a notable species of vigorous growth and branching habit. *P. sulphurea* is somewhat similar in character. It is quite rare, but is vigorous and hardy, and has beautiful golden stems. *P. mitis* is a handsome Bamboo that attains a considerable height, and the stems grow very rapidly. The attractive striped stems of *P. Castillonis* render this species very distinct and beautiful; while *P. violascens* is also a very fine plant. In *P. flexuosa* we have a graceful kind of much merit that forms an attractive specimen. The graceful stems of *P. Henonis* bear masses of delicate green foliage, which give them the appearance of feathery fronds and render this one of the most charming of all the Bamboos. *P. boryana* is a vigorous species that has the stems marked with deep purple blotches.

We now come to those Bamboos which are natives of the Himalayas, and of these *Arundinaria aristata* is one of the most distinct and handsome. It has purplish stems and tessellated leaves, and with us has attained a height of 12 feet. *A.*

racemosa somewhat resembles *A. aristata* in character, but of the two I prefer the former. In *A. spathiflora* we have an elegant Bamboo. It is a tall plant, and has a dense, plumose habit of growth.

J. GARDNER.

Batsford Park Gardens, Gloucestershire.

THE WALL BELLFLOWER AND PINKS.

The illustration on this page represents a happy grouping of two different types of plants in the rock garden. In the foreground the dainty little blue Bellflower, *Campanula portenschlagiana*

THE WALL BELLFLOWER (*CAMPANULA PORTENSCHLAGIANA*) EFFECTIVELY GROUPED WITH DWARF HYBRID PINK.

or *C. muralis*, is tumbling in flowery masses over the faces of large boulders, while, higher up, hybrid Pinks of the smaller sections provide a carpet of glaucous grey foliage, freely bedecked in the latter days of May and during June with flowers of varying shades of pink. The *Campanula* is one of the best of a large family for the rock garden, or for the interstices of dry walls or paved footways, making dense tufts of green foliage that are attractive from spring till autumn. It appreciates a rather sunny situation and good moist loam that contains a fair percentage of leaf-mould. The hybrid Pinks, in common with most of the race, thrive in rather poor calcareous soil.

SOME GOOD GREENHOUSE CLIMBERS.

THERE are many greenhouses, especially lofty structures, and what are generally termed conservatories that might be made much more attractive by the judicious employment of climbers. Bare walls could be covered, pillars clothed, and ironwork supporting the roof could also be covered, with charming effect. Some gardeners object to climbers on the score of insect pests, particularly mealy bug; but the enthusiastic grower will not be daunted by such trifles, and really they are nothing more, providing the plants are well grown and they are not allowed to become unwieldy, entangled examples of sheer neglect.

Where a large space has to be covered, the best results will be obtained by planting the climbers in a prepared border, but in many instances those grown in pots will suffice. For the majority the ordinary potting mixture of loam, leaf-soil and sand is recommended, and little difficulty will be experienced in regard to cultivation if the plants are not allowed to become dry at the base. When first brought into the greenhouse it is advisable to carefully train each shoot until the allotted space is filled, then the shoots can be permitted to take their normal course to a certain extent. The pruning consists of thinning out the weak shoots and cutting back the stronger ones to the prescribed area, and it is usually carried out immediately after flowering. The syringe should be employed on all favourable occasions, and whenever possible a solution of some reliable insecticide may be used. A suitable opportunity usually presents itself when the plants on the stages are removed or rearranged.

A Selection of Climbers. —

There are quite a series of these useful subjects, some of which produce most beautiful flowers. Taking them in more or less alphabetical arrangement, the first to receive notice will be the Bignonias, a group of vigorous climbers that require a light, sunny position to secure a full crop of bloom. *B. capensis*

has clusters of orange scarlet flowers, which are very attractive; *B. Cherere* is orange colour, and *B. speciosa* pink, stained with purple. *Brachysema acuminata* is a good pillar plant with red flowers, and the popular *Bougainvillea glabra*, with its rosy lilac bracts, should also be noted. The *Cestrum*s are very free flowering and suitable for pillars, and the blooms are borne in dense clusters at the apices of the growths. Three desirable kinds are *C. aurantiacum* (yellow), *C. elegans* (carmine) and *C. Newellii* (bright red). *Clematis indivisa* is an elegant climber with its loose trusses of creamy white flowers, and, for those who seek something out of the ordinary run, the *Glory*

Pea (*Clianthus puniceus magnificus*). It is a most distinct plant, of great beauty, and the bright crimson scarlet blossoms are always admired. Fuchsias are often employed with fine effect, especially such kinds as *The Shah*, *Clipper*, *Mrs. Rundle* and *Olympia*; while *Hibbertia dentata* is a pretty climber with yellow flowers. Both *Lapageria rosea* and *L. alba* should be included. *Lasiandra macrantha* (which also goes under the names of *Pleroma* and *Tibouchina*) is a hard-wooded plant with large, rich violet blue flowers. *Mandevilla suaveolens* is generally grown in the greenhouse, its large, pure white flowers being delightfully fragrant. The *Passifloras* (Passion Flowers) are greatly admired by some for their ornamental foliage and free-flowering qualities. A few of the best are *Allardii*, *cærulea*, *Constance Elliott* and *racemosa*.

Plumbago capensis, with its large heads of cobalt blue flowers, need hardly be mentioned, as it is so well known. There is a white form distinguished by the name of *alba*. The *Solanums*

also thrive in the greenhouse, where it is not so susceptible to mealy bug and scale. *Streptosolen Jamesonii* has showy trusses of bright orange flowers, and *Swainsona galegifolia* (deep red) with the variety *alba*, which have Pea-like flowers, are often seen in many greenhouses. The *Tacsonias*, which are allied to the Passion Flowers, are most beautiful climbers. *T. exoniensis* is rich carmine pink, and one of the best is the scarlet *Van Volxemii*. Several of the *Tropæolums* are excellent, and the glorious *Ipomœa Heavenly Blue* should be raised from seed each year.

T. W. B.

EARLY FLOWERING OR BORDER CHRYSANTHE- MUMS.

THIS desirable race of *Chrysanthemums* is responsible for much of the brightness of the

show signs of becoming dull rather early; but if it can be arranged to replace the plants with *Chrysanthemums*, the change is invariably appreciated. To grow plants for either purpose, they should be potted up early and given an open position in order to encourage well-ripened growth. Select the best plants and use them with a view to well furnishing the receptacle, but not to the extent of hindering growth through overcrowding. There is no advantage to be gained through using soil too rich, but firm potting is essential, and feeding may commence with weak liquid manure in August. Clear water must, however, be afforded freely whenever necessary, or the plants will become disfigured through the loss of the lower leaves. As early as possible attend to staking, for, once the stakes are in position, the rest, if attended to at short intervals, takes up little time; but it results in the plants being displayed to the best advantage. For this purpose the *Massé* family and the brilliant yellow variety *Horace Martin* stand unequalled.

Planting Out.—Plants intended for purely garden purposes and rooted in March will now be well established and ready for planting out. These *Chrysanthemums* are not very exacting in their requirements; any average garden soil will suit them. But the best results are obtained where it has been lightly manured and dug over in the winter. An open position away from overhanging trees gives better plants and earlier flowers than result when the plants are obliged to grow in partial shade. Yet with the exception of lateness the older varieties are most useful for planting in positions that enjoy the barest minimum of sunshine. Previous to planting, the surface soil should be broken up with the fork and afterwards made fine with the rake. Each plant should be allowed a space of 2 square feet, and the soil around the roots should be made firm, giving water, if necessary, after a neat stake has been fixed to each plant. Beyond an occasional watering in dry weather and keeping the surface soil stirred with the hoe, no other attention except that needed in tying is necessary.

Some Good Varieties.—Of varieties the following are very reliable. Most of them are at their best in September, are of good habit of growth, and possess a free-flowering nature. Some varieties are seen to advantage when disbudded, and where this style is favoured, handsome flowers may be obtained from *Countess* and *Queen of the Earlies* among the whites. *Polly* and *Mrs. J. Fielding* are good in the orange and bronze shades. Among the reds, *A'mirante*, *Crimson Polly*, *Goacher's Crimson* and *Mrs. W. Sydenham* are worthy of note. Excellent yellows will be found in *Cecil Wells*, *Cranford Yellow*, *Early Buttercup* and *Golden Glow*; while for pink varieties *Hector*, *James Bateman*, *Cranford Pink* and *Dolly Reeves* should not be overlooked. For massing and cutting in sprays, the *Massé* family and their sports are indispensable. Other notable varieties are *Roi des Blancs*, *Market White*, *Framfield Early White* and *La Nova* among those with white flowers. *Carrie*, *Leslie*, *J. Bannister* and *Champ d'Or* give a profusion of yellow flowers. Bronze shades are seen at their best in *Abercorn Beauty*, *Nina Black*, *Bronze Goacher* and *Diana*. Among the crimson shades are *Crimson Diana*, *Wells' Crimson*, *Claret* and *Ethel Blades*; while in the mauve and pink varieties *Dorothy Ashley*, *Lillie*, *Mabel Roberts*, *Perle Rose*, *Normandie* and *Patricia* are noteworthy.

F. J. TOWNEND.

THE NEW PRIMULA ADONIS THAT RECEIVED AN AWARD OF MERIT IN LONDON LAST WEEK. (See page 225.)

should be represented by *S. jasminoides*, a pretty species with clusters of white flowers slightly tinged with blue, these being borne in great profusion from spring to autumn. In favoured localities it will succeed in the open if given a sheltered position, especially in Devon and Cornwall. *S. Wendlandii* is most attractive, the lilac blue flowers being from 2 inches to 3 inches across. It is well adapted for pillars, the roof, and is a good plant for pot culture.

Smilax, whose elegant, twining stems are largely used for decorative purposes, is botanically known as *Myrsiphyllum asparagoides*. It should be trained on strings, which can be easily removed when required. The sweet-scented *Scaphanotis floribunda* is often consigned to the stove, but it will

average garden in the early autumn. When it is possible to devote a bed or a border to them, they are never seen to better advantage, and in the mixed border they are none the less attractive.

Plants in Pots.—But there are positions in many gardens where planting them in the ordinary manner would be out of the question, and yet in the autumn their presence would add much to the charm of the surroundings. Under such circumstances it is convenient to have a batch potted up, and if they are liberally treated, the results will amply repay for the trouble. Then there are often placed in positions of prominence ornamental receptacles filled with different types of bedding plants. In some cases these may

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Brasso-Cattleya Cliftonii Fowler's Variety (B.-C. digbyana-Mossiae x C. Trianae).—A hybrid of handsome proportions and considerable beauty. The glistening white sepals are suffused pink, the large lip fringed with a small blotch of crimson purple on the front lobe and coloured yellowish in the throat. From J. Gurney Fowler, Esq., Pembury, Kent.

Narcissus Cædmon.—A lovely Poeticus variety of the highest merit. The perianth segments are very solid-looking and pure; the cup is well bordered with crimson. From Messrs. Barr and Sons, Covent Garden, W.C.

AWARDS OF MERIT.

Narcissus White King.—A Giant Leedsii of handsome size and of ivory white colour, with a suspicion of palest sulphur in the crown. This fine variety, raised, we believe, by the Rev. J. Jacob, has passed into the hands of Messrs. J. R. Pearson and Sons, Lowdham.

Narcissus Mary Copeland.—We were informed that this belongs to the double incomparabilis class. It had been removed long before closing-time, and we did not see it. From Mr. Copeland.

Narcissus Marseillaise (Poeticus).—A large and shapely flower of good substance and great purity. The crimson rim is well defined.

Narcissus Distich (Poeticus).—The flower is large and the perianth segments somewhat more pointed than is usual in the Poeticus class. These two came from Messrs. F. H. Chapman, Limited, Rye.

Brasso-Cattleya vilmoriniana Shrubbery Variety (Cattleya Mossiae x B.-C. Mrs. Jeeman).—The rosy purple sepals render this very distinct and beautiful. The fringed lip is reticulated with crimson and clouded with orange in the throat. From Mr. F. Menteith Ogilvie, Oxford.

Lælio-Cattleya Isabel Sander (L.-C. canhamiana alba x C. Mossiae reineckiana).—Sepals

suffused purple, throat coloured deep orange. From Sir Jeremiah Colman, Gatton Park, Reigate.

Primula Adonis.—A very beautiful sort, having a handsome truss of large and shapely blossoms of rosy purple with distinct white eye. It has all the boldness and freedom of flowering

How to Force the Roots.—On a dry and well-situated spot of the garden a trench is made about 4 feet in breadth and 15 inches in depth. At the bottom you put a bed of mould 2 inches thick. The roots are placed perpendicularly, leaving a space of 1½ inches in every direction.

SECTIONAL VIEW OF A BED FOR FORCING CHICORY OR WITLOOF. THIS IS THE SYSTEM USED EXTENSIVELY IN BELGIUM. A CHICORY PLANT IS SHOWN AT END.

and petals white and very pure; lip white, of P. intermedia, but the raiser is emphatic that it was not evolved from that source. It is a particularly good plant. See illustration page 224. From Mr. J. Douglas, Great Bookham.

Hydrangea Radiant.—The heads of bracts are of rosy red hue and showy in the extreme. It is one of the Lemoinei hybrids, and certainly the best of its colour yet seen. From Messrs. George Paul and Son, Cheshunt.

The foregoing awards were made by the Royal Horticultural Society, before whom the plants were exhibited, on April 27.

THE CULTIVATION OF CHICORY OR WITLOOF.

AS the culture of Chicory is still little known here, I thought I might be useful to my English friends by writing about a method that is quite practical for large private gardens. Chicory constitutes a savoury vegetable in the winter and spring, whether cooked whole and seasoned with juice or white sauce, or used as a salad.

Sowing Seed.—This is how one proceeds to obtain good results. Early in May one sows seed broadcast or in lines on soil that has been well prepared beforehand, and which has assimilated the fertilising properties of manure, in order to obtain roots that will be of good shape and of average size. It is preferable to sow in lines 12 inches apart and at a depth of 1 inch. As soon as the plants have four leaves, they are thinned out in such a manner that they will be 8 inches apart in the lines. This will enable the cultivator to weed and clean easily between the rows. It would be imprudent to sow before the month of May, because one would probably see the plants running to seed.

Autumn Treatment of the Roots.—Towards the end of October or during November the Chicory roots are lifted and the foliage cut away about an inch above the neck. This foliage constitutes a good food for horned cattle. For working easily a choice of roots is made, and those of an average size are taken, say, about two inches in diameter at the top. If the roots are bigger, they produce side shoots, and this makes the Chicory lose its value and beauty. If the roots are too thin, the produce will be less. At the same time, all of them must be cut to a uniform length.

At the same time, care must be taken to put a mixture of earth and mould after each row, so that each root will be surrounded with good nutritive and well-aired ground, or the radicles of the roots will be delayed in sprouting. On this put a layer of garden soil half an inch thick which has been first sifted. If a light soil has to be dealt with, it must be pressed lightly. If it is a heavy or clayey soil, then it is useless to press, for the cones of the Chicory come forth from that which the leaves ought to assimilate in order to be able to break through the bed of earth, and the motto "Union is strength" gives a proof of this, for in any other way the scattered leaves could only break through with very great difficulty, and would have the form of cones no longer.

For forcing Chicory we put a layer of manure to a breadth of 18 inches and 1 foot in thickness, in order to produce an even temperature and so that the fermentation may be regular all over the bed. If the fermentation is thought to be too excessive, it can be ascertained by making an opening and passing the hand down the bottom of the roots, and, when a certain heat is felt, it will be as well to take away one layer of manure for four or five hours in order to cool it. After that the manure can be put back.

Chicory does not need a high temperature. Generally it is ready for picking in about a month. For this reason it is forced in batches in order to have successive crops lasting all the season. The trenches are covered with straw mats or rush mats, or even planks which have been prepared for this purpose, so as to preserve them from rain and in order to prevent the foliage decaying. To pick Chicory, the trenches are opened as far as it is necessary to gather just what is needed, and great care must be taken to cut the leaf-cones level with the neck of the roots. The roots of Chicory are a good food for cattle, and sometimes good use is also made of them in the kitchen.

For packing for distant countries it is necessary that the cones should be rolled up in paper separately, and especially to preserve them from moisture. If the package can reach its destination in one day, it is sufficient to close the basket firmly, so that the Chicory leaf-cones may not be displaced in transit. The forcing of Chicory is also carried out by means of thermo-siphon, this way of forcing being too complicated for mention here.

VICT. VANDE VELDI

PLAN OF A FORCING BED FOR CHICORY OR WITLOOF.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Permanent Vines.—As the bunches become ripe, the atmosphere must be kept dry, leaving the ventilators open both top and bottom at all times. If the roots require watering, afford them a moderate supply of clear tepid water. To keep the bunches in good condition as long as possible, cover the glass with a light shading. Weak limewash or two or three thicknesses of fish-netting will help to break the fierce rays of the sun. Artificial heat will now only be necessary to keep the atmosphere dry.

Midseason Vines.—Complete the final thinning of the bunches before the berries become too crowded, or the Grapes may be disfigured by rubbing. When the final thinning is done, mulch the border with rich farmyard manure; then thoroughly soak the border with tepid water. All lateral growth must now be regularly removed. Should red spider attack the leaves, sponge them with a weak solution of soft soap and sulphur.

Inarching Vines.—Any undesirable varieties may easily be replaced by inarching better sorts upon them. A shoot should be selected as near to the base of the rod as possible on which to inarch the scion. Young Vines struck from eyes last year and cut back in the winter make the most suitable scions. These are now in active growth, which is just the time for the operation to be accomplished.

Plants Under Glass.

Greenhouse Climbers.—These being now in active growth, require regular attention to the tying and regulating of the young shoots. Some will need to be severely thinned out, or the shoots will become hopelessly entangled. Light fumigations occasionally will destroy aphids, but red spider, thrips and mealy bug must be more severely dealt with. Plants growing in pots, also those which are well established in narrow, restricted borders, should be liberally fed with stimulants.

Calanthes.—Much care must be exercised with the management of these till they have become well rooted. The syringe will supply all the water necessary till the roots begin to permeate the soil. Even then water ought to be afforded with great care. A mean temperature of 65°, together with plenty of atmospheric moisture, will encourage a healthy growth. The plants must be shaded from bright sun.

Coleuses.—Pot on the young plants before they become potbound, and keep them growing in a warm house fully exposed to the sun. Keep the atmosphere moist by damping down the floors and staging frequently, but keep the foliage dry.

The Flower Garden.

Roses.—Attacks of mildew should be anticipated by regular spraying of the plants with some approved mildew specific. The same advice may also be urged in regard to aphids. Caterpillars must also be constantly watched for and picked off. A dusting of soot or guano previous to a storm will be of considerable benefit to old-established plants.

Spring-Flowering Plants.—Attention must now be directed to the propagation of plants for next season's bedding. Wallflowers may be sown thinly in drills on a well-prepared border. Polyanthuses should be sown in boxes and placed in a cold frame till the seeds have germinated. Aubrietias may be sown in frames. The named varieties are easily propagated from cuttings, which are now plentiful. The half-ripened shoots are most suitable for this purpose. Arabis is easily propagated from cuttings or by the division of the old plants. Pansies may be sown in a cold frame. Silene and Alyssum should be sown outdoors on a border which is not exposed to the full glare of the sun. Campanula pyramidalis is an excellent plant for the mixed border. Seed should be sown now in boxes and placed in slight warmth to germinate, afterwards growing the seedlings in a cold frame.

The Hardy Fruit Garden.

Outdoor Figs.—One of the chief causes of failure in regard to the culture of outdoor Figs

is that of allowing the trees to become congested with growths. Therefore all surplus shoots must be removed at regular intervals, thus allowing light and air free access to the remaining growths. Trees growing against walls or fences ought to be well supplied with moisture at the roots, giving plenty of stimulants to old-established trees.

Early Strawberry Runners.—It is an excellent plan to make a new plantation every year for the purpose of supplying early runners both for planting out and for forcing in pots. From such a plantation strong plants may be obtained for planting out in August, which will give a moderate crop of high-class fruits the following season. Plants intended for this purpose must have their flower-spikes removed; and in order to keep them free from weeds and promote a strong growth, hoe frequently between the rows.

The Kitchen Garden.

French Beans.—A sowing of an early kind can be made in pots or boxes and placed in heat. The seedlings may be planted in a cold frame, and will give a good return before those which are planted outdoors.

Cauliflowers.—The plants which were put out last month must be well supplied with water, should dry weather set in. Put out later plants when ready and keep a sharp look-out for slugs, or blanks are sure to occur. Make another sowing for the latest supplies.

Brussels Sprouts.—The earliest batch should now be ready for putting out. Plant in rows 2 feet 6 inches apart, allowing 2 feet between the plants. Thoroughly water them in and keep them well supplied with water till they are established.

Savoy Cabbages.—Another sowing of these may be made for the latest planting. Sow thinly in drills about a foot apart. If the ground is dry, water the drills before sowing. Should birds be troublesome, fish-netting ought to be placed over the seed-bed till the seedlings are well above the ground.

Lockinge Gardens, Berks.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Beetroot.—The present time is quite early enough to sow the main crop of this vegetable. If sown earlier, the roots are very apt to become too large and coarse. For preference sow on ground which has been well treated last season, such as where Celery grew; then it will not be necessary to add manure. If sown on ground which has been newly manured, the roots are liable to grow forked and so spoil the crop.

Peas.—The sowing of late and maincrop varieties must soon be completed, as the late supply can be obtained by sowing early varieties during June. Early Peas now growing should be staked as soon as they are a few inches above the ground.

Potatoes now appearing through the soil ought to be earthed up to protect them against a possible frost. It will also get rid of any weeds which may be troublesome.

Parsley which was raised from seed sown indoors during February or March may now be planted out, allowing a distance of a foot between the plants. After planting, a dusting of soot can be given.

Broccoli.—This date is suitable for sowing late winter and spring Broccoli, particularly if it is to be grown on moderately rich ground, as plants from earlier sowings are apt to make too free and soft a growth, which does not stand the frost so well as small, hardly grown plants.

Cauliflowers.—The plants which are to succeed the autumn-sown batch should now be planted in the open. Lift carefully with all the roots possible attached, and plant with the trowel. Surround each plant with soot as a protection from slugs.

Spinach.—The autumn-sown crop can now be dug into the ground, as better quality is to be had from the crop sown in March. As the plants will be better thinned, they should be pulled for that purpose, as well as for supplying the kitchen.

Fruit Under Glass.

Early Melons.—As the fruits approach the ripening period, slightly drier conditions must prevail. Water should almost be withheld from the roots, giving only sufficient when it is necessary to prevent the plants from flagging. Much more air must be admitted on all favourable occasions. This change of conditions towards the time of ripening will prevent to a large extent the splitting and decay of fruits reaching maturity, besides helping them to develop better flavour. Sow seed now to produce plants to take the place of the early crop when it has become exhausted.

Early Vines.—As the Grapes are colouring, more air ought to be admitted, leaving a little on both top and bottom ventilators during the night, except when very cold or stormy. Although damping should not be done so frequently, an occasional damping down during bright days will do no harm, and will certainly help to keep red spider in check.

Plants Under Glass.

Primula malacoides.—For winter and spring flowering this pretty Primula should now be sown. If it is not overpotted and is watered carefully, it is simple to grow. There is now a white form; but, except that it is a change, the original coloured kind is by far the most desirable for general use.

Malmaison Carnations in 6-inch pots which are developing their flower-stalks should be neatly staked with light Bamboo canes. A top-dressing of Clay's Fertilizer or some special Carnation manure will be of assistance, and for a change of diet some weak soot-water can be given. The older plants which are in bloom need heavier shading during bright sunshine, but care should be taken that it is not overdone, or the plants will lose that healthy colour one likes to see. The stages and paths ought to be thoroughly damped down once on all fine days.

Liliums.—Bulbs which were potted a few weeks ago are now growing freely, and require top-dressing. Use good loam mixed with a little leaf-soil or peat, also sand and a sprinkling of fertiliser. Auratums and lancifoliums, to be had in flower by July and early August, require to be kept moving in a genial growing atmosphere. They should, however, not be unduly forced. Green fly, which is generally troublesome on these plants, to be kept in check must be killed either by fumigation or by spraying with an insecticide.

Tree Carnations.—When the stock of any variety is limited and it is desired to increase it, old plants may be partly shaken out of their present pots and given a slight shift. Any leggy or bare pieces of growth can be cut away to encourage as much young growth as possible near the base of the plant.

The Flower Garden.

Chrysanthemums, if properly hardened off, may now be safely planted out. There is now no end to the number of early flowering varieties, and apart from their use for making a display during the autumn, they have few equals for cutting purposes.

Antirrhinums.—Where the beds or borders are not at present occupied by spring bedding plants, it will leave less to be done later on when the rush of general bedding out takes place if the Antirrhinums are put out now, as they are quite hardy plants.

Spring Bedding.—This display will now be at its best, and notes should be taken with a view to any alterations or improvements that can be effected for another season. Where spring bedding is carried out to any large extent, the summer bedding plants must necessarily be put out rather later to allow bulbous and other plants to partly mature their growth before being disturbed.

Sweet Peas having now started to grow, after recovering from the check of being planted out, should have any protecting material removed. During wet or showery weather a sharp look-out must be kept for slugs, which are very active during the evenings. The number of growths allowed to remain on each plant ought not to exceed three if high-class blooms are expected.

JOHN JEFFREY.

(Head-gardener to Sir R. W. Buchanan Jardine, Bart.)

Castlemilk Gardens, Lockerbie, N.B.

CELERIAC AND ITS CULTIVATION.

CELERIAC or Turnip-rooted Celery has for some time been cultivated in this country, but I am much surprised, considering its great value as a winter vegetable, that it is not grown much more extensively. For some years past it has been imported in very large quantities, both from France and Germany, and good prices have been realised; but as this is not likely to be the case during the present year, we should do well to avail ourselves of the opportunity of making good the deficit.

Fortunately, few vegetables are more easily grown, providing, of course, the right treatment is bestowed on it. Like Celery, it most certainly pays for liberal cultivation, and unless fair-sized, well-developed roots are produced, the crop will be of little value. An open piece of ground ought to be selected, which should be deeply cultivated and heavily manured, for preference during the winter months. The seed should be sown during March, raised in gentle heat, pricked off, treated as young Celery, and planted out about the second week in May. The surface should be broken down, raking it as level as possible. Allow a distance of from 20 inches to 24 inches between the rows, and 15 inches to 18 inches from plant to plant. Make very firm and give a thorough watering in. The crop should be constantly hoed and fresh soot frequently applied. At no time must the plants be allowed to suffer from the want of water; indeed, it is safe to say that during spells of drought it is practically impossible to give too much. The drainings from the farmyard, properly diluted, should be given occasionally. Beyond keeping down the weeds, it will occasion very little further trouble until the time of lifting, which should be done immediately the growth is completed and sharp frost is likely to occur, when it must be taken up, trimmed, and stored in sand or ashes in a cold, frost-proof place, where it will be found to keep in perfect condition all through the winter.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree.

SPECIES TULIPS IN POTS.

AFTER a good many attempts, I have this year been able to produce blooms on *Tulipa saxatilis*, which, I believe, is more than a good many people can do from bulbs of their own growing. Different positions in my garden, and even cold frame treatment in a sunny position all the winter long and right on till flowering-time have in the past all failed to secure what I desired. In the autumn of 1913 I had a present of some collected bulbs from Mr. C. G. van Tubergen, jun., of Haarlem, part of which were planted in a cold frame and the rest potted. These latter did very little, and but very few flowered (not that the others were any better). They were, however, well looked after, and were kept under glass and fed with diluted cow-manure water until the leaves died away. They remained where they were until September, when they were repotted and consigned to a cold frame, from which they were removed to a cool greenhouse

at the end of February. This spring I have had the gratification of a good show of bloom. In addition to the collected bulbs, I bought a few other species in 1913, and the two lots were grown together.

I have entered into all this in order to suggest the suitability of the combination of cold frame and cool house treatment for species in general. Among those that have given good results under the above conditions are the following: *Tulipas Greigii*, *fosteriana*, *kaufmanniana*, *k. coccinea*, *Ingens*, *polychroma*, *montana*, *dasystemon*, *persica*, *primulina*, *biflorus*, *armena*, *præstans tubergeniana*, *Eichleri*, *Willmottii*, *saxatilis*, *Orpanidesii* and *galatica*. From each of these and from the collected species I have had blooms quite as good in all cases as, and, in *most*, better than, I had from the self-same bulbs last year. One pot of a newly collected kind labelled with me No. 1 was particularly good. It was, I believe, a yellow form of *Greigii* known as *G. aurea*, but the surprise was that three of the four bulbs in the pot were *deliciously* scented with an aroma of Lily of the Valley. One of the three might be described as overpoweringly strong. I also found some plants of ordinary *Greigii* were very sweet, and had the same scent of Lily of the Valley or *Lachenalia glaucina*. This was new to me, although I have had the same variety out of doors off and on for a long time. I wonder if I have hit upon a good way of growing these species. When I have summered and wintered them again, I ought to know for certain, as three years should constitute a reliability trial. Meanwhile I thought my experience might be of interest to growers and would-be growers of Tulips. The essentials seem to be (1) cold frame treatment in their early stages of growth; (2) cool house treatment for ripening the bulbs; and (3) extra nourishment during this latter time. These are the only differences between my former way of growing species and what has been done in the last two years. Perhaps some other growers will relate their experiences. It will be a gain if we all know an infallible method of how to flower and keep these fine plants.

JOSEPH JACOB.

FLORICULTURE IN AMERICA.

SEVERAL floral subjects of much merit have recently appeared here in America which deserve to be more widely known by English gardeners. These include, first, a superior form of *Freesia refracta alba* called Fletcher's Improved Purity.

I notice that Messrs. Mauger and Sons of Guernsey make *F. r. a. major* a synonym of Purity. The latter was first brought to general notice a few years ago by Mr. Fisher, a grower in California. At any rate, Purity and major are both large-flowered varieties, and it is a selection from Purity that Mr. F. W. Fletcher of Auburndale, Mass., has worked up, and which he now calls his Improved Purity. Mr. Fletcher, by the way, is known to readers of THE GARDEN as the raiser of *Antirrhinum Nelrose*, the bright rose pink winter bloomer, which is also a good summer flower. It was he who introduced Violet Marie Louise to commerce in the United States of America, and was instrumental in naming that plant of great commercial value here—the Boston Fern (*Nephrolepis exaltata bostoniensis*). He has a stock of 160,000 corms or bulbs of his new large

white *Freesia*, and appears to have no difficulty in selling them at a highly remunerative price. There is no doubt about the merits of his flowers. The commercial florists in the wholesale markets at Boston and New York were paying him 50 per cent. more for his blooms in February than for the best of any other grower. He advertised them to retailers at 3dol. per 100 sprays. Many of the individual blooms are fully 2 inches across the mouth, deep in proportion, glistening pure white, and very solid. They are also fragrant, but less so than the parent type. He grows them in small houses in beds or benches 5 inches deep.

The second subject that thoroughly deserves to be taken up is Mr. J. A. Peterson's new winter-flowering *Begonia* that is named in honour of his wife. Mr. Peterson was born in Denmark, and was well drilled in European ways before making his home in this country, which owes so much to European horticulturists. He and his family now conduct a floricultural business at Cincinnati, Ohio, under the style and title of J. A. Peterson and Sons. He has raised several good *Begonias* of the Gloire de Lorraine type, the two best of those first introduced being named Glory of Cincinnati and Melior. The latter is a derivative of the French word *mellieur*, and as Melior came after "Glory," the inference is that it is better. It has larger flowers and even a freer habit of blooming. *Begonia* Mrs. J. A. Peterson, the third of the series, whose parentage is stated to be *socotrana* and *Gloire de Sceaux*, is a gem indeed. Save in the pinkish or carmine edge to the neat, small leaves (of the *Gloire de Lorraine* type) and their bronzy metallic appearance, there is nothing else of *Gloire de Sceaux* evident. All the plants I have seen exhibited at several exhibitions were only 6 inches to 9 inches high, in 4½-inch and 5-inch pots, and absolutely smothered in rich crimson or deep carmine pink flowers. The flowering habit is so pronounced that the plant never can grow lax or big. It reminds me of Veitch's *Agatha*, only the colour is different and the leaves are more attractive. Mr. Peterson states that the same plants will remain presentable and, indeed, attractive from October until early in March, or even later.

Thirdly, a decorative incurved, bright silvery pink *Chrysanthemum* that all the leading growers have been exhibiting, which is named Lillian Doty, might very well be given a trial. It succeeds out of doors at Mr. Charles H. Totty's, Madison, N.J. He grows it between his span-roofed greenhouses with the hardy, early flowering decorative and Pompon *Chrysanthemums*; but it is as a pot subject that it is seen at its finest. Grown as a free-branching plant, 4½ feet high or a little more, and the terminals disbudded to one or two flowers at most, it then produces orbicular, shell pink blooms of a somewhat stellate character. It is not easy to convey a true description of these pretty blooms; but each petal has a spiky look, giving the flower its rosette, starry appearance. As a cut bloom it is exquisite, albeit quite formal, and lasts for many days even in a warm, dry sitting-room. The largest blooms have a diameter of about three inches. I believe it is generally classed as a Pompon here; but Pompons are somewhat differently understood in England and in America, just as Rembrandt Tulips are, and it is surely best described as a decorative incurved, on the lines of those of the old Rundle family.

Fourth, and lastly, Mr. William Tricker, formerly of Lady Warwick's at Dunmow, Essex,

who is now one of the leading authorities in America on aquatic plants and Water Lilies in particular, has been exhibiting blooms of the blue *Nymphaeas* all the winter, and has reason to be satisfied with the monetary returns from the sale of them to the chief retail florists in New York. I think the returns have been a dollar a dozen. These are, of course, the tender *Nymphaeas*, of which there are several species that are practically ever-blooming, at least in this country of much sunshine. These embrace *capensis*, *cærulea*, *pulcherrima* and its improved form *Pennsylvania*, and the hybrid form of *micrantha* named *daubeneyana*. These are all day-flowering *Nymphaeas*. In addition there are the white night bloomers, *dentata superba* and *d. magnifica*, also *rubra rosea*. Each of these eight blooms freely in the winter in water at a temperature not lower than 65° up to 70° Fahr., and an atmospheric temperature a little lower for preference. There has been some amount of confusion as to the distinctions of *cærulea*, *capensis* and *stellata*. The latter does not appear to be generally recognised in this country, yet the authorities at Kew place *cærulea* as a variety of *stellata*, a species that Mr. James Hudson has made widely known in the gardens at home. These matters apart, however, it seems to have been with the blue-flowered, viviparous-leaved *daubeneyana* that Mr. Tricker has been working most, using this evidently as one parent in all his crosses. The varieties he has been showing and whose flowers he has been selling are *daubeneyana*, Mrs. Woodrow Wilson (lavender blue, suffused with rose) and Panama Pacific (blue, spotted with reddish brown). These are strong growers, and they are likely to find wide acceptance.

New York.

J. HARRISON DICK.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

CROWN IMPERIALS FAILING (M. L.).—We cannot understand why your Crown Imperials should fail to produce flowers, as you say that they are very healthy. The position should suit them quite well; in fact, they succeed with either a south, west or east exposure. They like rich soil of a loamy character, and should be planted from 4 inches to 6 inches below the surface of the soil. They may be lifted as soon as the stems have died down and can be replanted at once, or stored in a cool room and planted in the autumn.

TREES AND SHRUBS.

PROPAGATING RHODODENDRONS (A. Reader).—Seeds of *Rhododendrons* should be sown in February or March on the surface of sandy peat in pots or pans. If any covering of soil is given, it must only be a very light one of sandy peat. As a rule, however, the seeds are sown on the surface of the soil without covering, and a sheet of glass is placed over the pot or pan, that being covered again by a sheet of brown paper. Stand in a warm and moist greenhouse, and supply water by soaking the pans in a bucket or tub, so that the water will gradually rise through the soil. As soon as the young plants appear, remove the glass and stand the pans on a shelf near the light, taking care to provide shade from bright sun. As soon as the seedlings are large enough to handle, prick them off in pans or boxes about an inch apart each way. When 1 inch or 2 inches high, plant them in a border in rows 9 inches apart, and the plants about three inches apart in the rows. Some *Rhododendrons* can be increased by means of cuttings, those of small growth with small leaves being the most successful. Take cuttings of the current year's shoots, 3 inches to 4 inches long, in July, and dibble them into pots of sandy peat made moderately firm. Stand in a close frame until rooted; then treat them as recommended for seedlings. The vigorous-growing *Rhododendrons* can be increased by layering the lower branches into light soil. They may be pegged down any time between February and the autumn, but should not be disturbed for at least two years. Examine them after that time, and if well rooted, cut them away from the parent plants. A good layer of decayed leaves placed over the layered parts of the branches will assist in the formation of roots.

THE GREENHOUSE.

ADVICE ON GERANIUMS (Sheffield).—No wonder some of your *Geraniums* have a dried-up appearance, as they should not have been left without water all the winter. It is more than probable that some of the worst are past recovery, and it is not likely that many of the others have good, healthy roots. In this case your better way will be to shake them quite clear of the old soil and repot in some suitable compost. The good, healthy ones may be put into larger pots—that is, if the roots are vigorous; but in the case of the ailing ones, they should be put in comparatively small pots, shifting them into larger ones when the roots are active. After the plants are repotted, enough water must be given to keep the soil fairly moist, but not too wet. At this season they will do well in a house without any fire-heat. Cuttings taken from old plants now will root readily. They should be about four inches long, cut off at a joint, and dibbed into well-drained pots of sandy soil. Water should be given in moderation, and when the cuttings are well rooted they may be potted off. In future it will be as well to remember that in wintering *Geraniums* in a heated structure, enough water should be given to keep the soil slightly moist. Of course, an excess must be avoided, while, on the other hand, extreme dryness is equally injurious.

ROCK GARDEN.

PLANTS FOR WALL (C. B. A.).—Unless you favour the more diminutive alpine, a 2-feet high wall, no matter how constructed, does not admit of much scope. For effect the simpler way would be to plant from the top, using such things as *Thymes*, *Phloxes*, *Aubrietias*, double *Arabis*, *Alyssum*, alpine *Poppy*, *Linaria alpina*, *Wall-flower*, dwarf *Snagdragon*, *Thrift*, alpine *Pinks* and other plants. Some of these would grow erect and others trail to the ground. By arranging a trench-like cavity on the wall top so that the soil would be retained, planting could be done with ease and the plants be given a fair chance of success. In building so low a wall, a hollow-centred erection filled with mortar rubble, soil and grit would have been best, and, planting from top pockets, much success might have resulted. If you elect to plant it with the smaller-growing things, you might pick at will from the *Encrusted Saxifrages*, *Sedums*, *Cobweb House-leeks*, *Erinus alpinus* in variety, *Linaria pilosa*, the dwarfest alpine *Pinks* and others. Any of these would do for the sunny side, while the dwarfest *Ferns* and Mossy *Saxifrages* might be attempted on the northern side. If the wall is quite vertical and no set-back courses have been arranged to receive and retain moisture, much attention will be required after planting is done.

MISCELLANEOUS.

GOAT-MANURE, VIOLET BED, ETC. (A. L. S.).—All animal manures are good for garden purposes. If you have a quantity of the goat-manure, stack it for six months with its own bulk of soil. At the end of that time it might be used freely to all vegetable and flower crops. Permanent success with a Violet-bed is very often a question of soil and locality, though such beds are rarely allowed to stand longer than two years. The better way is to raise young plants annually, inserting cuttings in the autumn and planting out in March and April. For light soils cow-manure is best. It should be dug in well below the plants. Soot applied to the soil and dug in also is a useful fertiliser. Syringing periodically with soot-water during hot weather helps to keep red spider in check. The best early *Violets* for market purposes are given frame culture. By giving this, length of stem and clean flowers are assured. *La France*, *Princess of Wales*, *Victoria* and *Wellsiana* are the best singles; Mrs. J. J. Astor, *Comte de Brazza*, *De Parme* and *Marie Louise* the best doubles. The cloches manufactured by the Continuous Cloche Company can be obtained from Messrs. Waterer, Sons and Crisp, 10, The Arcade, Liverpool Street, E.C.

NAMES OF PLANTS.—C. C.—1, *Corydalis bulbosa*; 2, *Pulmonaria officinalis*, will grow in shade.

SOCIETIES.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE usual spring show of this society was held in the Waverley Market, Edinburgh, on April 28 and 29. As was anticipated, on account of the war leading to a reduction in many garden staffs, reduced railway facilities and other cognate causes, the number of entries showed a considerable reduction, being about 400 as compared with about 470 last year. The quality, however, was of a high order, and many exhibitors must have strained every effort to exhibit in such excellent style. All reduced fares having been suspended, the attendance was naturally smaller; but, taking it all over, the show was a success, which redounded to the credit of the executive and the exhibitors. It may be mentioned that soldiers in uniform were admitted at half the usual charges.

Although of smaller numbers than usual, owing to the absence of some of the trade exhibitors from a distance, the display from the trade was of special excellence, the firms which contributed making a most effective use of the capital material they brought forward. This may be gathered from the awards made in the non-competitive section. Among the exhibits were the following:

Messrs. Storrie and Storrie, Glencarse, made one of their usual highly effective displays of fruit trees in pots,

magnificent *Cinerarias*, *Calceolarias*, *Primulas*, &c. Gold medal. A similar award was made to Messrs. Hogg and Robertson of "Holland in Ireland," Dublin, for one of their imposing groups of *Tulips*, *Narcissi*, &c., the flowers including a number of novelties of much merit.

From Messrs. Cunningham, Fraser and Co., Edinburgh, there came a capital rock garden exhibit daintily arranged with many choice alpine, dwarf shrubs, &c., including their new yellow *Rhododendron*. A gold medal was awarded to this fine exhibit. A similar honour went to a magnificent group sent by Mr. David King, Osborne Nurseries, and staged at the west end of the Market. This comprised a charming display of spring flowers, with forced plants, &c. It was well worthy of the recognition it received.

Mr. John Downie, Edinburgh, also received a premier award for a notable group of *Rhododendrons*, &c.

Messrs. R. B. Laird, Dickson and Sons, Limited, Edinburgh, contributed a capital group on the floor, this embracing *Roses*, *Hydrangeas*, and other flowering and foliage plants. A gold medal was given to this fine exhibit.

Messrs. Young and Co., Hatherley, Cheltenham, sent one of their choice exhibits of *Carnations*, which was much admired. Silver-gilt medal.

Messrs. John Forbes (Hawick), Limited, were similarly honoured for their exhibit, which was strong in *Violas*, *Primulas* and a number of other spring flowers.

Messrs. James Cocker and Sons, Aberdeen, also received a silver-gilt medal for an attractive show of alpine and other spring flowers, together with good *Roses*; and Mr. D. McLeod also had his choice group of *Orchids* honoured by a silver-gilt medal.

Messrs. Reamsbottom and Co., Geashill, Ireland, made one of their brilliant displays of *St. Brigid Anemones*, &c. Silver medal.

Mr. David W. Thomson received a silver medal for a beautiful group of *Narcissi*.

Awards of merit were given to Messrs. James Cocker and Sons, Aberdeen, for two of their new *Polyanthuses*, *Bon Accord Peach* and *Bon Accord Indigo*.

Two other non-competitive but private exhibits received the well-merited distinction of gold medals. One went to a charming variety of new *Narcissi* raised by Mr. W. G. Pirie, gardener to C. W. Cowan, Esq., Dalhousie Castle, many of them worthy to take a good place in the famous collection there; and one to Mr. R. Hindle, 17, Blacket Place, Edinburgh, for a choice and well-cultivated group of *Orchids*.

Unfortunately, the restrictions of space render it impossible to do full justice to the competitive classes, which were in most cases well contested, and included exhibits of very high quality.

Plants were excellent, Mr. S. Houlden having it all his own way in the group of *Orchids* on a space 8 feet by 8 feet.

Mr. A. Smith, The Neuk, Peebles, led for four stove or greenhouse plants; and the other pot plant classes, which comprised a brilliant display of bulbs and forced shrubs, &c., resulted in wins of first prizes by such competitors as Mr. J. A. Sword, Mr. D. Kidd, Mr. G. McKinnon, Mr. F. M. Urquhart, Mr. R. Whammell, Mr. J. R. Findlay, Mr. A. McMillan, Mr. J. Thom and many others.

Roses in pots were attractive, Mr. J. Thom carrying off the leading honours here, except for climbers, in which Mr. W. J. Galloway was first.

Astilbes, *Cyclamens*, *Calceolarias*, *Primulas* and other spring flowers were capital, and *Auriculas* were shown in greater numbers than one anticipated. Alpine plants were fine, the Dalhousie Castle collection having it all its own way in the leading class, and coming in first in that for six alpine. In the above classes the number of successful exhibitors was too great for detail.

Cut flowers made a capital display, and the same remark must apply to most of these classes. Mr. W. G. Pirie was first for twelve bunches of *Narcissi*; Mr. J. Simpson for twenty-four and twelve *Roses*.

Mr. D. Kidd led for twelve bunches of stove or greenhouse plants, and he was also awarded the first prize for a decorated dinner-table.

The only class for fruit was that for a dish of *Strawberries*, where Mr. Kidd came first with fine produce.

Vegetables were excellent for the season, Mr. J. Cossar being first with the collection. Other winners in this section were Mr. D. Kidd, Mr. W. Staward, Mr. D. Fraser, Mr. R. Stuart, Mr. J. Scott, Mr. W. Harper, Mr. W. G. Pirie, Mr. J. S. Ritchie, Mr. J. Paterson, Mr. D. A. Hill, Mr. A. Lauder and Mr. W. Brow.

The show was altogether a highly creditable one, and spoke well for the manner in which the gardeners of Scotland had endeavoured to overcome the difficulties of the situation. The arrangements of the Council and committees were excellent, and admirably carried through by their secretary, Mr. D. Mackenzie.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

THE closing meeting of the spring session took place on Wednesday, April 21, when there was a good attendance of members to hear a paper by Mr. W. H. Scott, gardener to Captain Coleridge, Twyford, on "Poisonous Plants." He treated his subject in a very interesting manner, referring to a great number of plants which possessed poisonous properties in a more or less degree. He directed attention to some of our most valuable articles of food being the products of poisonous plants, but by careful cultivation they lost their poisonous qualities. A good discussion followed, and a hearty vote of thanks was accorded Mr. Scott for his valuable paper. Several exhibits were staged.

THE GARDEN.

No. 2269.—Vol. LXXIX.

MAY 15, 1915.

NOTES OF THE WEEK.

Our Sub-Editor Again Wounded in Action.—We regret to state that our Sub-Editor, Mr. H. Cowley, has again been wounded in action, and is now in hospital at Oxford. We have no particulars of his injuries, but in a postcard received from him on Monday morning he states that he was wounded in the knee while bandaging another soldier in the trenches. His address at present is Rifleman H. Cowley 2477, Surgical 7, 3rd Southern General Hospital, Oxford.

The Flowering Cherries.—One of the most beautiful effects in gardens just now is provided by the double-flowering Cherries, tall, fairly quick-growing trees, the branches of which are wreathed their whole length with large clusters of snow white blossoms. Although these erect trees are fairly common, the weeping forms of the ornamental Cherry are seldom met with. The accompanying illustration represents a comparatively young tree, yet it is sufficiently advanced to indicate what a beautiful subject it would make for planting as an isolated specimen on a lawn, or, indeed, in almost any situation where its pendulous branches would have ample room to develop. If a background of dark-leaved conifers could be provided, so much the better.

A Handsome Crab Apple.—There is an almost endless number of Crab Apples that are ornamental for our gardens at this time of the year, all of which are beautiful either in flower or fruit, or both. One that stands out among them is *Pyrus niedzwetzkyana*, a native of South-West Siberia, bearing at the present time large Apple-like clusters of rich deep purple flowers $1\frac{1}{2}$ inches to 2 inches in diameter. The richness of colour is not confined to the flowers, the young leaves and the young wood when cut also being beautiful. In the autumn the tree is very attractive with its large, dark red, conical-shaped Apples. Considered by many to be a beautiful form of *Pyrus Malus*, it was introduced into this country about twenty years ago, so that it should be more often seen than it is.

The Chelsea Show.—Following our usual custom, our next issue, dated May 22, will be a

Special Double Number. In addition to the usual features, it will contain a full illustrated report of the Royal Horticultural Society's Spring Show, to be held in the Chelsea Hospital Grounds on Tuesday, Wednesday and Thursday next. The report will be written by experts who are thoroughly acquainted with the sections entrusted to them to describe. This issue will be on sale at all bookstalls and newsagents on Thursday,

ago last March the Broom was planted in its present position, and was then a small specimen, not more than a foot high, in a 5-inch pot. It will thus be seen that it grows fairly rapidly. Although planted in rather stiff loam, this, in common with most other members of the family, will do quite well in soil composed mainly of sand.

The Rose Maggot.—This insidious pest has appeared earlier than usual this year, and already we

have found it carrying out its work of destruction in some of the earliest varieties. Its presence can be detected by the leaves, at the tops of the young shoots, being fastened together, usually with a sort of web, and presenting a crumpled appearance. Whenever this is noticed, search should be made for the grub, which is usually ensconced in the leaves, where it feeds on the flower-bud. There is no satisfactory remedy beyond this searching. If left alone, the grub will destroy the flower; hence this note of warning.
